Management of AIDS-related Kaposi's sarcoma

Di Lorenzo G, Konstantinopoulos PA, Pantanowitz L, Di Trollo R, De Placido S, Dezube BJ. Lancet Oncol 2007; 8: 167–76.

Review of current treatment strategies and ongoing investigations.

Update on KSHV epidemiology, Kaposi sarcoma pathogenesis, and treatment of Kaposi sarcoma

Uldrick TS, Whitby D. Cancer Lett 2001; 30: 150–62.

Comprehensive review of KS, including etiology and treatment options.

First-Line Therapies

• Pegylated liposomal doxorubicin	A
• Paclitaxel	A
• Antiretroviral therapy	B
• Cryotherapy	B
• Radiotherapy	B
• Alitretinoin gel	A

PEGylated liposomal doxorubicin plus highly active antiretroviral therapy versus highly active antiretroviral therapy alone in HIV patients with Kaposi's sarcoma

Martin-Carbonero L, Barrios A, Saballs P, Sirera G, Santos J, Palacios R, et al; Caelyx/KS Spanish Group. AIDS 2004; 18: 1737–40.

Randomized study comparing pegylated liposomal doxorubicin (20 mg/m² every 3 weeks) plus ART versus ART alone showed a greater

response rate (76% vs. 20%, respectively, in the intent-to-treat analysis) in the former group.

Liposomal doxorubicin is currently the chemotherapeutic agent of choice.

A randomized controlled trial of highly active antiretroviral therapy versus highly active antiretroviral therapy and chemotherapy in therapy-naïve patients with HIV-associated Kaposi sarcoma in South Africa

Mosam A, Shaik F, Uldrick TS, Esterhuizen T, Friedland GH, Scadden DT, et al. JAIDS 2012; 60: 150–7.

Fifty-nine treatment-naïve patients were randomized to ART (stavudine, lamivudine, and nevirapine) and 53 to ART and chemotherapy (triomune plus bleomycin, doxorubicin, and vincristine). Overall KS response was 39% in the ART arm and 66% in the combination therapy arm. There was no survival difference.

Multicenter trial of low-dose paclitaxel in patients with advanced AIDS-related Kaposi sarcoma

Tulpule A, Groopman J, Saville MW, Harrington Jr W, Friedman-Kien A, Espina BM, et al. Cancer 2002; 95: 147–54.

Phase II trial of 107 patients showed a complete or partial response, with or without concomitant protease inhibitor of 59% and 54%, respectively.

Randomized trial of paclitaxel versus pegylated liposomal doxorubicin for advanced human immunodeficiency virus-associated Kaposi sarcoma

Cianfrocca M, Lee S, Von Roenn J, Tulpule A, Dezube BJ, Aboulafia DM, et al. Cancer 2010; 116: 3969–77.

Seventy-three patients with advanced HIV-associated KS were randomized to paclitaxel versus pegylated liposomal doxorubicin, both of which resulted in significant improvement of pain and swelling. Overall incidence of toxicity was greater in those treated with paclitaxel.

Highly active antiretroviral therapy in AIDS-associated Kaposi's sarcoma: implications for the design of therapeutic trials in patients with advanced, symptomatic Kaposi's sarcoma

Krown SE. J Clin Oncol 2004; 22: 399–402.

This article reviews the evidence regarding the use of monotherapy

in KS. In patients with early disease (stage T₀), 80% of patients who had not previously received ART showed regression with ART alone.

Cryotherapy for cutaneous Kaposi's sarcoma (KS) associated with acquired immune deficiency syndrome (AIDS): a phase II trial

Tappero JW, Berger TG, Kaplan LD, Volberding PA, Kahn JO. JAIDS 1991; 4: 839–46.

Subjects received an average of three treatments per lesion resulting in a 70% cosmetic response rate.

Radiotherapy of classic and human immunodeficiency virus-related Kaposi's sarcoma: results in 1482 lesions

Caccialanza M, Marca S, Piccinno R, Eulisse G. J Eur Acad Dermatol Venereol 2008; 22: 297–302.

A 98% clearance rate was reported in classic lesions, and a 91% clearance rate in HIV-associated lesions, with good overall tolerability.

Phase III vehicle-controlled, multicentered study of topical alitretinoin gel 0.1% in cutaneous AIDS-related Kaposi's sarcoma

Bodsworth NJ, Bloch M, Bower M, Donnell D, Yocum R, International Panretin Gel KS Study Group. Am J Clin Dermatol 2001; 2: 77–87.

Response rate was 37% (compared with 7% treated with vehicle).

Marginal response rate and exorbitant cost make the usefulness of this modality questionable. Tretinoin gel may be a reasonable alternative topical retinoid option (Topical treatment of epidemic Kaposi's sarcoma with all-transretinoic acid. Bonhomme L, Fredj G, Averous S, Szekely AM, Ecstein E, Trumbic B, et al. Ann Oncol 1991; 2: 234–5).

Second-Line Therapies

• Intralesional interferon	C
• Interferon- α_{2b}	C
• Intralesional vinblastine	C

Intralesional interferon-alpha and zidovudine in epidemic Kaposi's sarcoma

Dupuy J, Prize M, Lynch G, Bruce S, Schwartz M. J Am Acad Dermatol 1993; 28: 966–72.

Intralesional interferon- α (1 million units three times weekly for 6 weeks) showed a response rate of 85%, but this was not statistically significant.

Interferon-alpha2b with protease inhibitor-based antiretroviral therapy in patients with AIDS-associated Kaposi sarcoma: an AIDS malignancy consortium phase I trial

Krown SE, Lee JY, Lin L, Fischl MA, Ambinder R, Von Roenn JH. AIDS 2006; 41: 149–53.

The authors observed that the administration of interferon- α_{2b} led to limited improvement in KS lesions. The maximum tolerated dose was 5 million IU/day.

Intralesional vinblastine for cutaneous Kaposi's sarcoma associated with acquired immunodeficiency syndrome

Boudreaux AA, Smith LL, Cosby CD, Bason MM, Tappero JW, Berger TG. J Am Acad Dermatol 1993; 28: 61–5.

Responses were achieved in 88% of treated lesions, but pain and hyperpigmentation are common. Pain was minimized by the addition of bicarbonate-buffered lidocaine to the diluent.

Third-Line Therapies

• Bevacizumab	C
• Sorafenib	E
• Gemcitabine	E
• Lenalidomide	E
• Thalidomide	B
• Liposomal all-trans retinoic acid, intravenous	B
• Photodynamic therapy	B
• 9- <i>cis</i> -retinoic acid	B
• Etoposide	B
• Mechanistic target of rapamycin (mTOR) inhibitors (sirolimus/rapamycin)	C
• IL-12	C
• Matrix metalloproteinase inhibitor Col-3	C
• Halofuginone	C
• Imiquimod 5% cream	C
• Sodium tetradecyl sulfate 3%	C
• Surgical excision	E
• Antiviral agents (ganciclovir, valganciclovir, foscarnet)	B
• Intramuscular immunoglobulin	E

Phase II study of bevacizumab in patients with HIV-associated Kaposi's sarcoma receiving antiretroviral therapy

Uldrick TS, Wyvill KM, Kumar P, O'Mahony D, Bernstein W, Aleman K, et al. J Clin Oncol 2012; 30: 1476–83.

Seventeen patients with HIV-associated KS were treated with bevacizumab, an anti-vascular endothelial growth factor A (VEGFA) monoclonal antibody. Overall response rate (complete response plus partial response) was 31%.

A Kaposi's sarcoma complete clinical response after sorafenib administration

Ardavanis A, Doufexis D, Kountourakis P, Rigatos G. Ann Oncol 2008; 19: 1658–9.

This is a report of a clinical response of KS to sorafenib (400 mg by mouth twice daily) when administered as treatment for renal cell carcinoma.

Gemcitabine for the treatment of classic Kaposi's sarcoma: a case series

Zustovich F, Ferro A, Toso S. *Anticancer Research* 2013; 33: 5531–4.

Four patients with classic KS successfully responded to gemcitabine as monotherapy.

Lenalidomide in treating AIDS-related Kaposi's sarcoma

Martinez V, Tateo M, Castilla MA, Melica G, Kirstetter M, Boué F. *AIDS* 2011; 25: 878–80.

Three cases are described of HIV-associated KS successfully treated by lenalidomide, an analog to thalidomide.

A retrospective analysis of thalidomide therapy in non-HIV-related Kaposi's sarcoma

Ben M'barek L, Fardet L, Mebazaa A, Thervet E, Biet I, Kérob D, et al. *Dermatology* 2007; 215: 202–5.

Only 3 of 11 patients achieved remission, with sensory neuropathy and vertigo limiting therapy in 27%.

A multicenter phase II study of the intravenous administration of liposomal tretinoin in patients with acquired immunodeficiency syndrome-associated Kaposi's sarcoma

Bernstein ZP, Chanan-Khan A, Miller KC, Northfelt DW, Lopez-Berestein G, Gill PS. *Cancer* 2002; 95: 2555–61.

A thrice-weekly dosing schedule (60 mg/m² escalating to 90 mg/m² and then to 120 mg/m² if tolerated) was more effective than once a week, without any significant difference in toxicity.

New photodynamic therapy protocol to treat AIDS-related Kaposi's sarcoma

Tardivo JP, Del Giglio A, Paschoal LH, Baptista MS. *Photomed Laser Surg* 2006; 24: 528–31.

Case report describing successful treatment of a solitary patient with epidemic KS.

9-cis-retinoic acid capsules in the treatment of AIDS-related Kaposi sarcoma: results of a phase 2 multicenter clinical trial

Aboulafia DM, Norris D, Henry D, Grossman RJ, Thommes J, Bundow D, et al. *Arch Dermatol* 2003; 139: 178–86.

Overall response was 19%. Moderate efficacy and substantial

toxicity at higher doses limit use.

Phase II evaluation of low-dose oral etoposide for the treatment of relapsed or progressive AIDS-related Kaposi's sarcoma: an AIDS Clinical Trials Group clinical study

Evans SR, Krown SE, Testa MA, Cooley TP, Von Roenn JH. J Clin Oncol 2002; 20: 3236–41.

Overall response rate was 36.1%; neutropenia and opportunistic infections were the most common side effects.

Sirolimus for Kaposi's sarcoma in renal-transplant recipients

Stallone G, Schena A, Infante B, Di Paolo S, Di Paolo S, Loverre A, et al. N Engl J Med 2005; 352: 1317–23.

All of 15 transplant patients achieved total remission when switched from ciclosporin to sirolimus for immunosuppression.

Classic Kaposi's sarcoma treated with topical rapamycin

Diaz-Ley B, Grillo E, Rios-Buceta L, Paoli J, Moreno C, Vano-Galvan S, et al. Dermatol Ther 2015; 28: 40–3.

An immunocompetent patient improved after 16 weeks of treatment with topical rapamycin.

Phase 2 study of pegylated liposomal doxorubicin in combination with interleukin-12 for AIDS-related Kaposi sarcoma

Little RF, Aleman K, Kumar P, Wyvill KM, Pluda JM, Read-Connole E, et al. Blood 2007; 110: 4165–71.

Thirty of 36 patients had a good response to liposomal doxorubicin with IL-12 for six 3-week cycles followed by twice-weekly IL-12 for maintenance for 3 years. No control group was included, and patients received highly active antiretroviral therapy (HAART) in addition to the experimental regimen.

Activity of subcutaneous interleukin-12 in AIDS-related Kaposi sarcoma

Little RF, Pluda JM, Wyvill KM, Rodriguez-Chavez IR, Tosato G, Catanzaro AT, et al. Blood 2006; 107: 4650–7.

IL-12 was administered twice weekly at varying doses. Significant results were observed at doses >100 ng/mg; side effects limited dosing above 500 ng/kg.

Randomized phase II trial of matrix metalloproteinase inhibitor COL-3 in AIDS-related Kaposi's sarcoma: an AIDS Malignancy Consortium Study

Dezube BJ, Krown SE, Lee JY, Bauer KS, Aboulafia DM. *J Clin Oncol* 2006; 24: 1389–94.

A response rate of 41% was observed at a dose of 50 mg/day. The medication was well tolerated overall.

Phase II AIDS malignancy consortium trial of topical halofuginone in AIDS-related Kaposi's sarcoma

Koon HB, Fingleton B, Lee JY, Geyer JT, Cesarman E, Parise RA, et al. *JAIDS* 2011; 56: 64–8.

Twenty-six patients with HIV and KS limited to the skin were treated with halofuginone (angiogenesis inhibitor) with response rate of 35%.

Imiquimod 5% cream for treatment of HIV-negative Kaposi's sarcoma skin lesions: a phase I to II, open-label trial in 17 patients

Célestin Schartz NE, Chevret S, Paz C, Kerob D, Verola O, Morel P, et al. *J Am Acad Dermatol* 2008; 585–91.

Imiquimod was applied under occlusion three times a week for 24 weeks. Eight of 17 patients showed some response, with 6 of 17 demonstrating tumor progression.

Intralesional vinblastine vs. 3% sodium tetradecyl sulfate for the treatment of oral Kaposi's sarcoma. A double blind, randomized clinical trial

Ramírez-Amador V, Esquivel-Pedraza L, Lozada-Nur F, De la Rosa-García E, Volkow-Fernández P, Súchil-Bernal L, et al. *Oral Oncol* 2002; 38: 460–7.

Sixteen patients were randomized to each arm. Results were equivocal but suggested a possibly greater tolerability of sodium tetradecyl sulfate.

Local therapy for mucocutaneous Kaposi's sarcoma in patients with acquired immunodeficiency syndrome

Webster GF. *Dermatol Surg* 1995; 21: 205–8.

Surgery can occasionally be helpful for isolated lesions, but recurrence is frequent; therefore this modality is of limited value.

Oral ganciclovir for patients with cytomegalovirus retinitis treated with a ganciclovir implant

Martin DF, Kupperman BD, Wolitz RA, Palestine AG, Li H, Robinson CA. N Engl J Med 1999; 340: 1063–70.

In this randomized controlled trial, intravenous and oral ganciclovir resulted in a decrease in the development of KS.

Effect of antiviral drugs used to treat cytomegalovirus end organ disease on subsequent course of previously diagnosed Kaposi's sarcoma in patients with AIDS

Robles R, Lugo D, Gee L, Jacobson MA. J AIDS Hum Retrovirol 1999; 20: 34–8.

In patients being treated for cytomegalovirus with foscarnet, progression of KS was markedly delayed.

Valganciclovir for suppression of human herpesvirus 8 replication: a randomized, double-blind, placebo-controlled, crossover trial

Casper C, Krantz EM, Corey L, Kuntz SR. J Infect Dis 2008; 198: 23–30.

Valganciclovir was noted to reduce the shedding frequency and quantity of HHV-8.

Successful treatment of classical Kaposi sarcoma with low-dose intramuscular immunoglobulins

Thoms KM, Hellriegel S, Krone B, Beckmann I, Ritter K, Schon MP, et al. Br J Dermatol 2011; 164: 1107–9.

Improvement was noted in a patient with intramuscular globulins.

Kawasaki disease

Michael Pan, Lauren Geller, Ranon Mann, Adam Friedman, and Adam Wulkan

Kawasaki disease (KD), seen primarily in infants and children, is an acute febrile multiorgan vasculitic process known for its mucocutaneous and nodal involvement. Although KD was described in Japan several decades ago, its pathogenesis has yet to be clarified. Increasing evidence supports an infectious etiology.

Management Strategies

The primary goal when treating a patient with KD is the prevention of cardiac complications, including coronary artery disease, aneurysm formation, myocardial infarction, and sudden death. Historically, the mainstay of therapy has been the use of high-dose *salicylates* (e.g., aspirin) and *intravenous γ -globulin* (IVIG) in order to manage the acute

inflammatory characteristics of this condition and to prevent the aforementioned cardiovascular sequelae.

In the acute inflammatory phase, aspirin, a potent inhibitor of prostaglandin synthesis, is initially dosed at 80 to 100 mg/kg/day orally, divided four times per day, for 2 weeks. After the patient is afebrile for 48 hours, the dose is reduced to 3 to 5 mg/kg orally daily and continued for 6 to 8 weeks until the erythrocyte sedimentation rate (ESR) and platelet count normalize. Multiple trials have failed to elucidate the benefit of high-dose aspirin therapy with regard to outcomes; therefore current evidence is insufficient to support the use of salicylates as an integral component of first-line therapy in KD.

IVIG is a known first-line therapy in the treatment of KD. IVIG, which can lead to rapid defervescence, is able to neutralize circulating myelin antibodies and to downregulate proinflammatory cytokines, including interferon- γ (INF- γ). The pediatric dosing, which is equivalent to the adult dosing, is 400 mg/kg/day intravenously over 2 hours as a single daily infusion for 4 consecutive days; alternatively, a single dose of 2 g/kg can be intravenously infused over 12 hours. Failure of IVIG therapy has been linked to a gene polymorphism in the plasma platelet-activating factor acetylhydrolase. No specific regimen has been assigned for these nonresponding cases.

Specific Investigations

- ESR, complete blood count + platelet count, lactate dehydrogenase
- Multidetector computed tomography (CT)
- Echocardiography

Kawasaki disease: an overview

Pinna GS, Kafetzis D, Tselkas O, Skevaki CL. *Curr Opin Infect Dis* 2008; 21: 263–70.

Echocardiography, stress imaging, angiography, magnetic resonance imaging (MRI), and ultrafast CT scans have been useful in the diagnosis of coronary aneurysms, occlusions, and stenosis. Echocardiography is recommended both at the time of diagnosis and after 2 to 6 weeks. It has recently been demonstrated that multidetector CT is preferable to transthoracic echocardiography or MRI. CT can detect calcification and estimate soft plaques and offers rapid data collection and simple interpretation of images, all of which

serve as an advantage over other diagnostic modalities. Conversely, MRI cannot offer rapid capture of images, thus prolonging the time under anesthesia and its associated risks. Transthoracic echocardiography can only image the proximal arteries and therefore cannot reliably detect stenosis.

The diagnosis and treatment of Kawasaki disease

Royle J, Burgner D, Curtis NJ. *Pediatr Child Health* 2005; 41: 87–93.

These guidelines highlight the difficulties in the diagnosis of KD. A meta-analysis of recent data offers insight that may assist in the early recognition of this important pediatric disease. The clinical features are common to many other childhood illnesses, so the diagnostic criteria are not highly sensitive. Blood serologies and chemistries may be helpful, but none is diagnostic and most have a low specificity. The echocardiogram should not be used as a diagnostic test. A normal echo does not exclude KD, as coronary lesions generally occur in the convalescent phase and may develop as late as 6 to 8 weeks after the onset of fever. Because there is no specific diagnostic test for KD, increased awareness of the epidemiology and the spectrum of clinical presentation is essential for early recognition and optimal management.

First-Line Therapies

• Immunoglobulin	A
• Aspirin	B

Kawasaki disease: an update on diagnosis and treatment

Kuo HC, Yang KD, Chang WC, Ger LP, Hsieh KS. *Pediatr Neonatol* 2012; 53: 4–11.

An update on treatment modalities, including methylprednisolone, TNF- α antagonists, statins, plasma exchange, and cytotoxic agents. It

concludes that high-dose aspirin does not appear to decrease the incidence of coronary artery lesions (CALs), although further studies are required.

Treating KD refractory to IVIG is a therapeutic challenge. Recent studies have shown associations of age, platelet count, ESR, hemoglobin, C-reactive protein (CRP), eosinophil count, lactate dehydrogenase (LDH), albumin, and alanine aminotransferase (ALT) with failure of primary treatment with IVIG. Because IVIG failure has an increased risk of CALs, it is essential to treat such patients with a second dose of IVIG, intravenous methylprednisolone, or a TNF- α inhibitor.

Resistance to intravenous immunoglobulin in children with Kawasaki disease

Tremoulet AH, Best BM, Song S, Wang S, Corinaldesi E, Eichenfield JR, et al. J Pediatr 2008; 153: 117–21.

IVIG treatment for the acute stage of KD has been shown to be effective and safe. However, it is known that 10% to 20% of patients are resistant to initial therapy (2 g/kg IV). These patients are at increased risk for the development of coronary artery abnormalities. Using demographic and laboratory information on IVIG-resistant cases, this retrospective study attempted to develop a scoring system to help identify future resistant cases among patients in San Diego County. This would perhaps indicate the need for secondary therapies early in the treatment of these patients. Unfortunately, the diversity of the patient population did not allow for the development of an accurate and clinically useful scoring system.

Analysis of potential risk factors associated with nonresponse to initial intravenous immunoglobulin treatment among Kawasaki disease patients in Japan

Uehara R, Belay ED, Maddox RA, Holman RC, Nakamura Y, Yashiro M, et al. Pediatr Infect Dis J 2008; 27: 155–60.

Some KD patients do not respond to initial treatment with IVIG. The purpose of this study was to determine potential risk factors associated with IVIG nonresponse among KD patients in Japan. The results emphasize that physicians should consider IVIG nonresponse in patients with recurrent KD, as well as in KD patients diagnosed and treated before the fifth day of illness who continue to have laboratory values associated with nonresponse, such as low platelet count and elevated ALT and CRP. These patients may benefit from

the administration of a second-line treatment early during the illness in addition to the initial IVIG treatment.

Treatment of acute Kawasaki disease: aspirin's role in the febrile stage revisited

Hsieh KS, Weng KP, Lin CC, Huang TC, Lee CL, Huang SM. *Pediatrics* 2004; 114: 689–93.

In North America, high-dose aspirin (80–100 mg/kg/day orally) is widely used during the acute phase of KD. However, the necessity of this therapy has yet to be elucidated. This study indicated that treatment in the acute stage of KD without aspirin had no effect on the response rate of IVIG therapy, duration of fever, or incidence of coronary abnormalities. This response was seen when children were treated with high-dose (2 g/kg) IVIG as a single infusion, regardless of whether treatment was commenced before or after day 5 of illness. Therefore the available data show no appreciable benefit of aspirin in preventing IVIG nonresponse, aneurysm formation, or shortening of fever duration.

High-dose aspirin is associated with anemia and does not confer benefit to disease outcomes in Kawasaki disease

Kuo HC, Lo MH, Hsieh KS, Guo MM, Huang YH. *PLoS One* 2015; 10: e0144603.

This retrospective study analyzed 851 KD patients who had received single-dose IVIG along with either (1) high-dose aspirin until defervescence followed by low-dose aspirin ($n = 305$) or (2) low-dose aspirin only ($n = 546$). There were no significant differences in IVIG resistance rate, CALs, or duration of hospital stay. Furthermore, this study found that after IVIG, the group that received high-dose aspirin had lower hemoglobin levels and higher serum CRP and hepcidin levels with delay in normalization. The authors concluded that high-dose aspirin does not confer any benefit and is unnecessary in the acute phase of KD.

Second-Line Therapies

• Corticosteroids	A
• Retreatment with immunoglobulin	D

Efficacy of immunoglobulin plus prednisolone for prevention of coronary artery abnormalities in severe Kawasaki disease (RAISE study): a randomised, open-label, blinded-endpoints trial

Kobayashi T, Saji T, Otani T, Takeuchi K, Nakamura T, Arakawa H. Lancet 2012; 379: 1613–20.

This multicenter, prospective, randomized trial took place at 74 hospitals in Japan. Individuals with severe KD were randomized to receive either current standard of care IVIG (2 g/kg/day given over 24 hours) and aspirin (30 mg/kg/day) or IVIG and aspirin (same dose as control) plus prednisolone (2 mg/kg/day with 15-day taper after normalization of CRP). There were 125 assigned to the intervention group and 123 received only IVIG. The incidence of CALs was significantly decreased in the intervention arm with intravenous prednisolone (4 patients) versus the control arm (28 patients). Larger studies involving individuals from various ethnic backgrounds are needed.

Effects of steroid pulse therapy on immunoglobulin-resistant Kawasaki disease

Furukawa T, Kishiro M, Akimoto K, Nagata S, Shimizu T, Yamashiro Y. Arch Dis Child 2008; 93: 142–46.

In this nonrandomized study, the effectiveness of intravenous methylprednisone (IVMP) was compared with that of additional IVIG (2 g/kg 12–24 hours) and aspirin (30 mg/kg/day) as second-line therapy for KD. Fever was rapidly alleviated after IVMP administration (30 mg/kg/day for 3 consecutive days with heparin infusion 10–20 U/kg/h) in all IVIG-resistant patients in the study; 77% recovered without recurrence of KD and did not develop coronary artery aneurysms. The findings suggested that early IVMP treatment in IVIG-resistant patients is as effective as treatment with additional IVIG as second-line therapy.

Risk factors associated with the need for additional intravenous

gamma-globulin therapy for Kawasaki disease

Muta H, Ishii M, Furui J, Nakamura Y, Matsuishi T. *Acta Paediatr* 2006; 95: 189.

The goal of this study, using data from a nationwide survey in Japan, was to identify the characteristics of patients who needed retreatment with IVIG. Elevated ESR, anemia, and high LDH are known predictive values for necessitating IVIG retreatment. In this study, male gender, incomplete and recurrent cases of KD, and treatment with IVIG at a dose of 1 g/kg or less within 4 days of illness onset were identified as independent risk factors associated with the need for retreatment. Identification of these risk factors would be beneficial to predict which patients might need IVIG retreatment. This could help physicians initially create a strategy to prevent cardiovascular complications in these patients.

Third-Line Therapies

• Ciclosporin	B
• Ticlopidine	E
• Pentoxifylline	B
• Ulinastatin	B
• Infliximab	A
• Plasma exchange	B
• Rituximab	E
• Dipyridamole	E
• Cardiac transplantation	E
• Coronary artery bypass grafting	B

Cyclosporin A treatment for Kawasaki disease refractory to initial and additional intravenous immunoglobulin

Suzuki H, Terai M, Hamada H, Honda T, Suenaga T, Takeuchi T, Hooshyar H, et al. *Pediatr Infect Dis J* 2011; 30: 610–5.

In this trial involving 28 individuals who failed IVIG therapy, ciclosporin 4 to 8 mg/kg/day oral administration was shown to be a safe, well tolerated, and efficacious option. Of the 28, 18 were afebrile within 3 days of therapy, 4 were afebrile within 4 to 5 days, and the remaining 6 failed to respond to treatment.

Response of refractory Kawasaki disease to pulse steroid and cyclosporin A therapy

Raman V, Kim J, Sharkey A. *Pediatr Infect Dis J* 2001; 20: 635–37.

A case of aggressive and protracted KD with coronary aneurysms, myocarditis, pericarditis, and valvular insufficiency, despite repeated

administration of IVIG, responded to combination therapy with pulse and high-dose corticosteroids and ciclosporin 3 mg/kg/day.

Ulinastatin, a urinary trypsin inhibitor, for the initial treatment of patients with Kawasaki disease: a retrospective study

Kanai T, Ishiwata T, Kobayashi K, Sato H, Takizawa M, Kawamura Y, et al. *Circulation* 2011; 124: 2822–28.

This is a retrospective study comparing 369 patients with KD who were treated with a combination of ulinastatin (UTI) at 15,000 U/kg/day divided into three doses, aspirin (30 mg/kg/day), and IVIG (1–2 g/kg) versus 1178 patients treated with IVIG and aspirin. Those treated in the UTI group experienced fewer CALs (3%) than those in the control group (7%). Thus treatment with UTI was associated with fewer rescue treatments and CALs.

Infliximab for intravenous immunoglobulin resistance in Kawasaki disease: a retrospective study

Son MB, Gauvreau K, Burns JC, Corinaldesi E, Tremoulet AH, Watson VE, et al. *J Pediatr* 2011; 158: 644–49.

This study, performed between 2000 and 2008, assessed fever duration and coronary artery dimensions in patients refractory to IVIG therapy who subsequently received either infliximab (5 mg/kg) or additional IVIG (2 g/kg). Individuals treated with infliximab experienced decreased fever duration and shorter hospitalization, yet similar coronary artery dimensions, compared with the control group.

Infliximab for intensification of primary therapy for Kawasaki disease: a phase 3 randomised, double-blind, placebo-controlled trial

Tremoulet AH, Jain S, Jaggi P, Jimenez-Fernandez S, Pancheri JM, Sun X, et al. *Lancet* 2014; 383(9930): 1731–38.

In this study, 196 patients were enrolled to receive either infliximab (single dose 5 mg/kg, $n = 98$) or placebo ($n = 98$) in addition to IVIG standard therapy. There was no significant difference in the rate of treatment resistance. However, there was a significant reduction in left anterior descending coronary artery Z-score, days of fever, and inflammatory markers in the group that received infliximab. No serious adverse events could be attributed to infliximab.

Resistant Kawasaki disease treated with anti-CD20

Sauvaget E, Bonello B, David M, Chabrol B, Dubus JC, Bosdure E. J Pediatr 2012; 160: 875–76.

A 6-year-old boy with KD refractory to IVIG and systemic steroids was successfully treated with rituximab (15 mg/kg/day), an anti-CD20 monoclonal antibody, initiated on day 20 of disease onset. Within 2 days of rituximab therapy, the child's fever had dissipated, and the echocardiography revealed improvement of the CALs.

Long-term efficacy of plasma exchange treatment for refractory Kawasaki disease

Hokosaki T, Mori M, Nishizawa T, Nakamura T, Imagawa T, Iwamoto M, et al. Pediatr Int 2012; 54: 99–103.

A retrospective study involving 125 patients with KD refractory to IVIG therapy treated with plasma exchange (PE) therapy. The success of PE therapy was dependent on both the presence of CALs before PE and on what day of disease onset the PE therapy was initiated. CALs remained in 2.8% of individuals treated with PE when PE was initiated before day 9 of the onset of KD. For those with CALs in whom PE was started after day 9 of KD onset, sequelae remained 15% of the time. For the 105 patients in whom the coronary arteries were normal before PE initiation, none of them went on to develop CALs. Thus PE therapy is optimal for refractory KD when used before the development of CALs.

Prevention of thrombosis of coronary aneurysms in patients with a history of Kawasaki disease

Suda K, Kudo Y, Sugawara Y. Nippon Rinsho 2008; 66: 355–59.

To prevent coronary thrombosis in KD, long-term antithrombotic therapy using antiplatelet drugs such as aspirin, dipyridamole, ticlopidine, clopidogrel, and abciximab, with or without warfarin, is recommended by official guidelines.

Optimal time of surgical treatment for Kawasaki coronary artery disease

Yamauchi H, Ochi M, Fujii M, Hinokiyama K, Ohmori H, Sasaki T, et al. J Nippon Med Sch 2004; 71: 279–86.

The authors studied 21 patients with KD and coronary complications who underwent coronary artery bypass grafting (CABG) over a 12-year period. They conclude that CABG is successful when completed shortly after the acute onset of disease.

Keloids

Brian Berman, Ran Huo, Martha Viera, and Andrea Maderal

Keloids are dermal hyperproliferative growths with excessive accumulation of dense fibrous tissue that may appear in areas of trauma. By definition, keloids are scars that extend beyond the borders of the original wound and do not regress spontaneously. In

addition to the cosmetic disfigurement and negative psychological impact that keloids may cause the patient, these scars can often present with intense pain and pruritus.

Management Strategy

The therapeutic options for keloids are numerous; however, there is no one modality that is considered to be universally safe and effective. Prevention of recurrence should be the main determinant in treatment selection. The initial rule of treatment involves *prevention* and *patient education*. It is of the utmost importance to close wounds with minimal tension and inflammation. Nonessential cosmetic surgery should be avoided in patients predisposed to developing keloids. These scars commonly develop in high-tension areas of the body. Incision sites in the skin of the midchest and skin overlying joints should be avoided, and surgical wounds should parallel skin creases.

Common therapeutic modalities include occlusive dressings, compression therapy, intralesional corticosteroid injections, intralesional interferon injections, intralesional 5-fluorouracil injections, cryosurgery, surgical excision, radiation therapy, and laser therapy. Because no single therapy is vastly superior or universally efficacious, combination therapies have led to the best success rates.

Intralesional corticosteroids have been the mainstay of treatment for keloids. The most commonly used is triamcinolone acetonide in concentrations of 10 to 40 mg/mL administered intralesionally with a 25- to 27-gauge needle at 4- to 6-week intervals. *Topical corticosteroids* and *topically applied corticosteroid-impregnated tape* are also used frequently; the basis for the latter involves recent data demonstrating that occlusion enhances percutaneous penetration of steroid by the formation of a drug reservoir within the stratum corneum. *Silicone gel sheets* and *silicone occlusive dressings* have antikeloidal effects, which appear to be a result of hydration.

Pressure devices are thought to induce local tissue hypoxia and have been shown to have a thinning effect on keloids. A novel idea in the treatment of keloids and hypertrophic scars is the use of *intralesional interferon- α_{2b}* , which has been used successfully to reduce scar height and postoperative recurrences, via a mechanism of collagen synthesis inhibition. *Interferon- γ* has also been evaluated in the treatment of

keloids, with modest results.

Cryotherapy can be used as monotherapy or in conjunction with other treatment modalities, most commonly triamcinolone, with reported efficacy. Its mechanism of action involves the induction of vascular damage and tissue anoxia that ultimately leads to necrosis. However, some reported side effects have included hypopigmentation and postoperative pain. A specialized intralesional needle cryoprobe method has been recently reported to result in better efficacy and fewer side effects.

Radiation therapy has been used as monotherapy or as an adjuvant to surgical excision. The carcinogenesis risks of radiotherapy are extremely small; however, the concept of using potentially harmful radiation to treat benign lesions is a persistent and important issue.

Surgical excision alone yields widely varying results with high (55%–100%) recurrence rates. The *combination of surgical excision with other modalities, such as intralesional corticosteroids or with pressure dressing, x-ray therapy, interstitial radiation, and brachytherapy*, reduces recurrence rates to a range of 10% to 50%.

CO₂ and argon lasers have been used in the past in the treatment of keloids but have recently been replaced by the *Nd:YAG and 585-nm pulsed-dye laser* because of their better efficacy and fewer adverse effects. *Intralesional injection of 5-fluorouracil* has been beneficial for hypertrophic scars and for keloids. *Bleomycin, retinoic acid, intralesional verapamil, and mitomycin C* have all been reported to have good efficacy in small clinical trials, but more clinical experience with these agents is needed.

Specific Investigation

- Skin biopsy

Dermatofibrosarcoma protuberans is a unique fibrohistiocytic tumor expressing CD34

Aiba S, Tabata N, Ishii H, Ootani H, Tagami H. Br J Dermatol 1992; 127: 79–84.

Dermatofibrosarcoma protuberans can be easily misdiagnosed as a keloid. Histopathology may help differentiate the two, but expression of CD34 by tumor cells occurs only in dermatofibrosarcoma protuberans.

First-Line Therapies

• Intralesional corticosteroids	B
• Compression	B
• Occlusive dressing	B
• Intralesional 5-fluorouracil	B

A new uniform protocol of combined corticosteroid injections and ointment application reduces recurrence rates after surgical keloid/hypertrophic scar excision

Hayashi T, Furukawa H, Oyama A, Funayama E, Saito A, Murao N, et al. *Dermatol Surg* 2012; 38: 893–7.

Twenty-one keloids were treated with surgical excision, then corticosteroid injections after removal of the sutures and every 2 weeks (for five more times) thereafter. In addition, all postsurgical wounds received self-administered steroid ointment application twice daily for 6 months after suture removal. Recurrence occurred in 3 of the 21 keloid cases (14.3%) and one of the six hypertrophic scar cases (16.7%).

Keloids treated with topical injections of triamcinolone acetonide. Immediate and long term results

Kiil J, *Scand J Plast Reconstruct Surg* 1977; 11: 169–72.

In a prospective clinical trial of 52 patients, intralesional injections of triamcinolone acetonide alone resulted in significant flattening and reduction of pruritus in 93% of the keloids. One third had partial recurrence at 1 year, and at 5 years more than 50% had recurred. All recurrences were successfully treated with further triamcinolone acetonide injections.

Outcomes of surgical excision with pressure therapy using magnets and identification of risk factors for recurrent keloids

Park TH, Seo SW, Kim JK, Chang CH. *Plast Reconstr Surg* 2011; 128: 431–9.

In this study, 1436 ear keloids in 883 patients were treated with surgical excision followed by pressure therapy using magnets. The overall recurrence-free rate was 89.4% after a follow-up period of 18 months. Keloid recurrence was significantly associated with the presence of prior treatment history, keloid low growth rate, and high patient body mass index.

A surgical approach for earlobe keloid: keloid fillet flap

Kim DY. *Plast Reconstr Surg* 2004; 113: 1668–74.

Surgical revision of keloids on earlobes followed by intradermal scaffold/linear surgical incision was performed in 19 subjects (26 earlobe keloids). At 12 months, the recurrence rate was 19.2%. There were no device-related adverse events.

Comparison of a silicone gel-filled cushion and silicone gel sheeting for the treatment of hypertrophic or keloid scars

Berman B, Flores F. *Dermatol Surg* 1999; 25: 484–6.

In this study of 32 keloid patients, 53% treated with silicone gel cushion and 36.3% treated with silicone gel sheeting had a reduction in keloid volume.

Clinical evaluation of a new self-drying silicone gel in the treatment of scars: a preliminary report

Signorini M, Clementoni MT. *Aesthet Plast Surg* 2007; 31: 183–7.

A prospective trial involving 160 patients that compared postoperative treatment with a self-drying transparent silicone gel with no treatment. Sixty-seven percent of patients in the treatment group had a significant improvement in scar quality.

Combination of different techniques for the treatment of earlobe keloids

Akoz T, Gideroglu K, Akan M. *Aesthet Plast Surg* 2002; 26: 184.

Nine patients were treated with surgical excision of their earlobe keloids, followed by triamcinolone acetonide injection and silicone gel sheets. No recurrences occurred in eight of the nine patients.

Intralesional 5-fluorouracil in keloid treatment: a systemic review

Bijlard E, Steltenpool S, Niessen FB. *Acta Derm Venereol* 2015; 95:

778–82.

Systematic review of 18 publications with 482 patients. 5-fluorouracil treatment was effective in 45% to 96% of patients, but only triamcinolone with 5-fluorouracil performed better than triamcinolone alone.

Comparison of the efficacy of intralesional triamcinolone acetonide and 5-fluorouracil tattooing for the treatment of keloids

Sadeghinia A, Sadeghinia S. *Dermatol Surg* 2012; 38: 104–9.

Forty patients were randomized to treatment with either intralesional triamcinolone acetonide injection or 5-fluorouracil tattooing every 4 weeks for 12 weeks. At 44-week follow-up, superior improvement was observed in the 5-fluorouracil group for lesion erythema, pruritus, height, surface, and induration. No side effect was detected in either of the groups.

Second-Line Therapies

• Intralesional interferon- α_{2b}	B
• Cryosurgery	A
• Radiation	B

Recurrence rates of excised keloids treated with postoperative triamcinolone acetonide injections or interferon alfa-2b injections

Berman B, Flores F. *J Am Acad Dermatol* 1997; 37: 755–7.

There was a statistically significant reduction in the recurrence of 124 excised keloids with postexcision interferon- α_{2b} (18.7% recurrence) versus excision alone (51.1%) and versus treatment with postoperative intralesional triamcinolone (58.4%).

Effects of interferon- α 2b on keloid treatment with triamcinolone acetonide intralesional injection

Lee JH, Kim SE, Lee A-Y. *Int J Dermatol* 2008; 47: 183–6.

Forty keloid lesions from 19 patients were treated either with triamcinolone acetonide intralesional (TAIL) combined with interferon- α_{2b} or with TAIL alone. Superior results were obtained with combination therapy, with more than 80% improvement in lesion depth and volume in most patients.

Cryotherapy in the treatment of keloids

Rusciani L, Paradisi A, Alfano C, Chiummariello S, Rusciani A. *J Drugs Dermatol* 2006; 5: 591–5.

Of 135 patients with 166 keloids treated with cryotherapy between 1990 and 2004, 79.5% responded very well with a volume reduction of 80% or more after three treatments. Median follow-up time was 4 years. The most common adverse effects included atrophic depressed scars and, in 75% of cases, residual hypopigmentation.

A comparison of the combined effect of cryotherapy and corticosteroid injections versus corticosteroids and cryotherapy alone on keloids: a controlled study

Yosipovitch G, Widijanti Sugeng M, Goon A, Chan YH, Goh CL. *J Dermatol Treat* 2001; 12: 87–90.

Ten patients with 28 keloids were treated with cryotherapy alone, steroid injection alone, or cryotherapy and steroid injection. At 8 months' follow-up the combination therapy was significantly better at reducing keloid thickness and pruritus than either treatment alone. None of the keloids treated with combination therapy recurred. No significant side effects were noted.

Hypofractionated electron-beam radiation therapy for keloids: retrospective study of 568 cases with 834 lesions

Shen J, Lian X, Sun Y, Wang X, Hu K, Hou X, et al. *J Radiat Res* 2015; 56: 811–7.

Retrospective study of 568 patients with 834 keloids treated with radiotherapy. Relapse rate was 9.59% and time to relapse 6 to 28 months. No radiation-induced cancers were observed.

Keloids can be forced into remission with surgical excision and radiation, followed by adjuvant therapy

Yamawaki S, Naitoh M, Ishiko T, Muneuchi G, Suzuki S. *Ann Plast Surg* 2011; 67: 402–6.

The authors treated 91 keloids in total, with 51 keloids (56.0%) resolved completely, by a combination of surgical excision and postoperative irradiation. Eighty-one keloids (89.0%) showed good results with additional treatment of intralesional steroid injections.

Treatment of keloids by surgical excision and immediate postoperative single-fraction radiotherapy

Ragoowansi R, Cornes PG, Moss AL, Glees JP. *Plast Reconstruct Surg* 2003; 111: 1853–9.

In a retrospective study of 80 patients treated with postoperative single-fraction radiotherapy, 9% of keloids relapsed after 1 year and 16% relapsed after 5 years.

Retrospective analysis of treatment of unresectable keloids with primary radiation over 25 years

Malaker K, Vijayraghavan K, Hodson I, Al Yafi T. *Clin Oncol J Roy Coll Radiol* 2004; 16: 290–8.

In this retrospective study involving 86 keloids in 64 patients, 97% of keloids showed significant regression after completing radiotherapy with either kilovoltage x-rays or electron beams, without significant side effects. The patients were treated with a total of 3750 cGy administered in five once-weekly fractions.

Postoperative high-dose-rate brachytherapy in the prevention of keloids

Veen RE, Kal HB. *Int J Radiat Oncol Biol Phys* 2007; 69: 1205–8.

Postoperative ¹⁹²Ir brachytherapy showed better cosmetic results at higher dosages, with only one keloid recurrence out of 38 observed after a once-administered 6-Gy and twice-administered 4-Gy regimen.

Postkeloidectomy irradiation using high-dose-rate superficial brachytherapy

Kuribayashi S, Miyashita T, Ozawa Y, Iwano M, Ogawa R, Akaishi S, et al. *J Radiat Res* 2011; 52: 365–8.

A total of 36 keloids were treated with high-dose-rate superficial brachytherapy after keloidectomy. The median follow-up period was 18 months (range 9–29 months). Only three keloids (9.7%) showed local recurrence.

Surgical excision with adjuvant irradiation for treatment of keloid scars: a systemic review

van Leeuwen MC, Stokmans SC, Bulstra AE, Meijer OW, Heymans MW, Ket JC, et al. *Plast Reconstr Surg Glob Open* 2015; 3: e440.

Systematic review of 33 articles that contained 3130 patients with 3470 keloid scars treated with excision followed by low-dose or high-dose brachytherapy. High-dose brachytherapy showed lower recurrence rates compared with low-dose brachytherapy and external radiation, and a short time (<7 hours) interval postexcision was associated with lower recurrence rate compared with long time interval (>24 hours).

Third-Line Therapies

• Laser surgery	C
• Imiquimod	A
• Mitomycin C	B
• Intralesional interferon- γ	C
• Topical retinoic acid	B
• Intralesional bleomycin	B
• Verapamil	B
• Surgery	B

Management of ear lobule keloids using 980-nm diode laser

Kassab AN, El Kharbotly A. Eur Arch Otorhinolaryngol 2012; 269: 419–23.

Twelve patients with a total of 16 lobule keloids were treated with 980-nm diode laser and subsequent intralesional triamcinolone acetonide injection. Between two and five treatment sessions led to 75% of patients with more than 75% reduction of keloid size, with no recurrence in the past 12 months.

Effect of pulse width of a 595-nm flashlamp-pumped pulsed dye laser on the treatment response of keloidal and hypertrophic sternotomy scars

Manuskiatti W, Wanitphakdeedecha R, Fitzpatrick RE. Dermatol Surg 2007; 33: 152–61.

In 19 patients with keloidal or hypertrophic median sternotomy scars, pulsed dye laser with pulse width of 0.45 ms was significantly effective in reducing scar volume and improving elasticity. However, the reported reduction in scar volume was only 24.4% after three treatments.

The effect of carbon dioxide laser surgery on the recurrence of keloids

Norris JEC. Plast Reconstruct Surg 1991; 87: 44–9.

In this retrospective study, 23 patients had adequate follow-up. One had no recurrence, 9 required corticosteroids to suppress recurrence, and 13 were considered to be treatment failures.

Pilot study of the effect of postoperative imiquimod 5% cream on the recurrence rate of excised keloids

Berman B, Kaufman J. J Am Acad Dermatol 2002; 47: S209–11.

Thirteen keloids were treated with excision and imiquimod 5% cream every night for 8 weeks. Ten patients with 11 keloids completed the 6-month study, and there were no recurrences.

Role of mitomycin C in reducing keloid recurrence: patient series and literature review

Gupta M, Narang T. J Laryngol Otol 2011; 125: 297–300.

Twenty patients with 26 earlobe keloids were treated with surgical shave excision and topical mitomycin C. No recurrences were noted after 24 months.

Intralesional interferon gamma treatment for keloids and hypertrophic scars

Larrabee WF, East CA, Jaffe HS, Stephenson C, Peterson KE. Arch Otolaryngol Head Neck Surg 1990; 116: 1159–62.

Five of the 10 study patients had a reduction in their scar size by at least 50% in linear dimensions. The treatment protocol was one treatment per week for 10 weeks. Up to 0.05 mg of interferon- γ was injected weekly.

The local treatment of hypertrophic scars and keloids with topical retinoic acid

Janssen de Limpens AMP. Br J Dermatol 1980; 103: 319–23.

There was a reduction in keloid size and symptoms in 77% of 28 intractable keloids treated with topical retinoic acid.

Treatment of keloids and hypertrophic scars using bleomycin

Aggarwal H, Saxena A, Lubana PS, Mathur RK, Jain DK. J Cosmet Dermatol 2008; 7: 43–9.

Over 3 months, four courses of bleomycin were administered through a multiple superficial puncture technique in 50 patients with keloids and hypertrophic scars. Forty-four percent of patients experienced complete flattening of lesions, and 22% showed more than 75% lesion regression.

Comparison of intralesional verapamil with intralesional triamcinolone in the treatment of hypertrophic scars and keloids

Margaret Shanthi FX, Ernest K, Dhanraj P. Indian J Dermatol Venereol Leprol 2008; 74: 343–8.

In this randomized, single-blind, parallel group study in which 54 patients were allocated to receive either verapamil (2.5 mg) or triamcinolone (40 mg) every 3 weeks up to 6 months, there was a reduction in vascularity, pliability, height, and width of the scar with both the drugs after 3 weeks of treatment. Triamcinolone had a faster reduction rate, but verapamil had a lower rate of hypopigmentation.

Keratoacanthoma

M. Laurin Council, and George J. Hruza

The Keratoacanthoma (KA) is a unique tumor of the skin with characteristics of both benign and malignant neoplasia. Typically, the

lesion presents as a rapidly growing (weeks to months) crateriform nodule on sun-exposed skin of the middle aged or elderly Caucasian. During the proliferative phase, lesions grow quickly and can reach an impressive size. Once mature, KA stops growing before involuting. If observed, resolution of a KA classically occurs within several months. Clinically and histologically, a KA shares several characteristics with well-differentiated cutaneous squamous cell carcinoma (SCC). Histologically, for example, lesions appear as a symmetric exoendophytic proliferation of glassy keratinocytes with a central keratin-filled crater. Because a KA can be impossible to discern from a well-differentiated SCC, some dermatopathologists refer to the lesions as *SCC, KA-type*. Unlike SCC, the lesions are often clinically self-limited and spontaneously regress. Before regression, a KA can cause significant local destruction and morbidity. Because of these features, many consider KA a form of aborted SCC or low-grade malignancy. Although KAs appear most commonly as solitary lesions, multiple lesions may occur in the setting of a genodermatosis (e.g., Ferguson-Smith, Witten and Zak, Grzybowski, or Muir-Torre syndrome); during koebnerization (after surgery, phototherapy, laser, or placement of a tattoo); or as eruptive lesions in response to certain systemic medications, such as ciclosporin, BRAF inhibitors, and vismodegib.

Management Strategy

Because an accurate distinction between a clinically low-grade KA and a more aggressive SCC is challenging histologically, lesions should be removed in their entirety whenever possible. Although several features have been described to distinguish a self-involuting KA from its more aggressive counterpart (such as fewer mitoses, less pleomorphism, and good demarcation), these histologic criteria can be noted in both lesions. Complete removal aids in diagnosis and prevents further growth and proliferation, with associated local destruction, and decreases the likelihood of metastasis in the event of histologic misclassification of a SCC as KA.

Once a diagnosis has been established, management aims to stimulate resolution, prevent local destruction, minimize the risk of recurrence, and achieve a favorable cosmetic outcome. Management of a KA is therefore dependent on the size and location of the lesion(s), the rate of growth, and the causative factors (if known).

Small, solitary lesions are best treated with *excision*, with complete margin analysis (Mohs micrographic surgery) where appropriate. Low-risk lesions in select candidates may be treated with destructive methods such as *cryotherapy or electrodesiccation and curettage*. If confidence in a diagnosis can be ascertained, observation can be entertained, but with great caution. *Large lesions may be treated with topical (imiquimod or 5-fluorouracil) or intralesional (5-fluorouracil, methotrexate, or bleomycin) chemotherapy or x-ray therapy*. Eruptive KAs are best treated by removal of the cause, when known and practical, by systemic therapy, or by field treatment with photodynamic therapy (PDT) or other topical mechanisms, such as 5-fluorouracil, with or without occlusion.

The level of evidence in the literature for the treatment of KAs is poor—typically anecdotal evidence of single case reports. Nevertheless, larger studies encompassing SCC can be pertinent to management of these unique lesions.

Specific Investigation

- Biopsy

Solitary keratoacanthoma

First-Line Therapies

• Mohs micrographic surgery	C
• Excision	C

AAD/ACMS/ASDSA/ASMS 2012 appropriate use criteria for Mohs micrographic surgery: a report of the American Academy of Dermatology, American College of Mohs Surgery, American Society for Dermatologic Surgery Association, and the American Society for Mohs Surgery

Ad Hoc Task Force, Connolly SM, Baker DR, Coldiron BM, Fazio MJ, Storrs PA, et al. J Am Acad Dermatol 2012; 67: 531–50.

Expert consensus panel recommends Mohs micrographic surgery as appropriate treatment for primary keratoacanthomas of any size on the head, neck, hands, feet, pretibial shin and genitalia; for lesions >1 cm on the trunk and extremities; for recurrent KAs of any size or location; and for keratocanthomas >0.5 cm on the trunk and extremities in immunocompromised patients.

Prognostic factors for local recurrence, metastasis, and survival rates in squamous cell carcinoma of the skin, ear, and lip

Rowe DE, Carroll RJ, Day Jr. CL. J Am Acad Dermatol 1992; 26: 976–90.

Authors evaluated the medical literature over a 50-year period to determine which treatment modality offers the best cure rate for SCC of the skin and lip. For primary tumors of the skin, Mohs micrographic surgery reportedly had a 3.1% recurrence rate at 5 years compared with 8.1% for surgical excision. For locally recurrent lesions, Mohs micrographic surgery reduced the rate of recurrence from 23.3% to 10%, compared with simple excision.

Keratoacanthomas treated with Mohs' micrographic surgery (chemosurgery). A review of forty-three cases

Larson PO. J Am Acad Dermatol 1987; 16: 1040–4.

During a 6- to 24-month follow-up period, one patient recurred (2.4%).

Second-Line Therapies

• Destruction	C
• Observation	C
• Intralesional chemotherapy	C
• Topical therapy	D
• Photodynamic therapy	D
• Radiation	C

Cryosurgery for skin cancer: 30-year experience and cure rates

Kuflik EG. Dermatol Surg 2004; 30: 297–300.

The author reports his experience using cryosurgery to a temperature of -50° to -60°C for 4406 new and recurrent skin cancers in 2932 patients. Of the 132 treated SCCs, no lesions recurred at 5-year follow-up.

Evaluation of curettage and electrodesiccation in the treatment of keratoacanthoma

Nedwich JA. Australas J Dermatol 1991; 32: 137–41.

A retrospective series of 111 KAs in 106 patients treated with curettage and electrodesiccation. A recurrence rate of 3.6% is noted after 3 to 26 months.

Natural course of keratoacanthoma and related lesions after partial biopsy: clinical analysis of sixty-six tumors

Takai T, Misago N, Murato Y. J Dermatol 2015; 42: 353–62.

Regression rate of KA was 98.1%, and that of KA-like SCC was 33.3%. No regression was noted in lesions classified histologically as crateriform or infundibular SCC.

Intralesional methotrexate treatment for keratoacanthoma

tumors: a retrospective case series

Aubut N, Alain J, Claveau J. *J Cutan Med Surg* 2012; 16: 212–7.

Complete response of 74% was noted in 46 cases; no significant adverse events. An average of 1.8 injection sessions was necessary, for a mean total dose of 10 mg.

Successful treatment of keratoacanthoma with intralesional fluorouracil

Goette DK, Odom RB. *J Am Acad Dermatol* 1980; 2: 212–6.

Case series of forty-one KAs in 30 patients were treated with weekly injections of 5-fluorouracil. Forty lesions cleared after an average of three injections.

Treatment of keratoacanthoma with intralesional bleomycin

Sayama S, Tagami H. *Br J Dermatol* 1983; 109: 449–52.

Six patients with biopsy-proved KA were treated with one or two injections of varying volumes of 0.5% bleomycin. All lesions regressed within 2 to 6 weeks of therapy.

Intralesional interferon alfa-2b treatment of keratoacanthomas

Oh CK, Son HS, Lee JB, Jang HS, Kwon KS. *J Am Acad Dermatol* 2004; 51: S177–80.

Four patients with histologically confirmed KA of the head or neck were treated with weekly interferon alfa-2b injections. All lesions resolved completely in 5 to 7 weeks.

Treatment of keratoacanthomas with 5% imiquimod cream and review of the previous report

Jeon HC, Choi M, Paik SH, Ahn CH, Park HS, Cho KH. *Ann Dermatol* 2011; 23: 357–61.

Complete regression was seen after 9 to 11 weeks in four patients with KA treated with imiquimod cream 5% three to four times weekly. In addition, the authors summarize seven other prior reports of imiquimod use in 14 total patients with KA of the face or hand. Complete remission was noted in all reported cases within 4 to 11 weeks; application frequencies ranged from twice daily to three times weekly.

Clinical efficacy of short contact topical 5-fluorouracil in the treatment of keratoacanthomas

Thompson BJ, Ravits M, Silvers DN. J Clin Aesthet Dermatol 2014; 7: 35–7.

Nine patients with biopsy-proven KA were treated with twice-daily 5-fluorouracil until complete resolution of the lesion (4–6 weeks). Two patients experienced temporary erythema, and all reported satisfaction with the treatment.

Efficacy of topical photodynamic therapy for keratoacanthomas: a case-series of four patients

Farias MM, Hasson A, Navarrete C, Nicklas C, Garcia-Huidobro I, Gonzalez S. Indian J Dermatol Venereol Leprol 2012; 78: 172–4.

Four solitary lesions cleared after three sessions of PDT with methyl aminolevulinic acid cream. No evidence of recurrence was noted, and excellent cosmetic outcomes were reported at 3 years of follow-up.

Radiation therapy of giant aggressive keratoacanthomas

Goldschmidt H, Sherwin WK. Arch Dermatol 1993; 129: 1162–5.

A retrospective review of 16 aggressive KAs, 14 of which had recurred after surgery, responded to a fractionated course of superficial radiation therapy with complete resolution and satisfactory cosmesis.

Multiple keratoacanthomas

First-Line Therapies

• Oral acitretin	E
• Oral isotretinoin	E
• Oral erlotinib	E
• Combination	D
• Radiation	C

Acitretin induces remission in generalized eruptive keratoacanthoma of Grzybowski

Sami N, Bussian A. Int J Dermatol 2015; 54: e67–9.

A 66-year-old woman presented with generalized eruptive KAs. After 6 months of acitretin 25 mg/d, all initial lesions resolved and no new lesions developed. The patient remained in remission at the time of reporting, 6 months after the discontinuation of the drug.

Generalized eruptive keratoacanthomas of Grzybowski treated with isotretinoin

Vandergriff T, Nakamura K, High WA. J Drugs Dermatol 2008; 7: 1069–71.

A 68-year-old man with generalized eruptive KAs of Grzybowski was started on 20 mg isotretinoin daily for 1 month. The dosage was increased to 40 mg daily an additional 3 months. Regression of lesions was noted, and no new lesions appeared. Two years after discontinuation of the medication, the patient remained in complete remission.

Treatment of multiple keratoacanthomas with erlotinib

Reid DC, Guitart J, Agulnik M, Lacouture ME. Int J Clin Oncol 2010; 15: 413–5.

An 82-year-old man with multiple KAs was started on 150 mg/day of the epidermal growth factor receptor inhibitor, erlotinib, which resulted in rapid clinical improvement.

Successful treatment of multiple keratoacanthoma with topical imiquimod and low-dose acitretin

Barysch MJ, Kamarashev J, Lockwood LL, Dummer R. J Dermatol 2011; 38: 380–2.

An 86-year-old woman with multiple KA of the lower extremity, recurrent after excision and radiation, was started on imiquimod 5%. Improvement, but not clearance, was noted until addition of acitretin 25 mg daily. Lesions resolved within 2 months of combination therapy and recurred abruptly upon discontinuation of therapy. Resumption of the topical and systemic treatments resulted in a sustained remission for 1.5 years while on treatment.

Superficial radiotherapy for multiple keratoacanthomas

Bruscino N, Corradini D, Campolmi P, Massi D, Palleschi GM. Dermatol Ther 2014; 27: 163–7.

A 76-year-old woman with multiple KAs was successfully treated with superficial radiotherapy. At 1 year's follow-up, resolution of the lesions was noted.

Keratoacanthomas related to predisposing factors

First-Line Therapies

• Cessation or completion of therapy	C
• Photodynamic therapy	E

Eruptive keratoacanthoma-type squamous cell carcinomas in

patients taking sorafenib for the treatment of solid tumors

Smith KJ, Haley H, Hamza S, Skelton HG. *Dermatol Surg* 2009; 35: 1766–70.

Fifteen patients taking the multikinase inhibitor sorafenib for solid tumors developed multiple KAs during therapy. Lesions resolved upon completion of sorafenib.

Eruptive keratoacanthomas associated with leflunomide

Tidwell WJ, Malone J, Callen JP. *JAMA Dermatol* 2016; 152: 105–6.

Case report of eruptive KAs associated with leflunomide for arthritis, which resolved upon cessation of leflunomide and initiation of oral isotretinoin.

Photodynamic therapy for multiple eruptive keratoacanthomas associated with vemurafenib treatment for metastatic melanoma

Alloo A, Garibyan L, LeBoeuf N, Lin G, Wechniak A, Hodi FS, et al. *Arch Dermatol* 2012; 148: 363–6.

Case report of multiple KAs in the setting of vemurafenib therapy treated with multiple cycles of photodynamic therapy. Treated areas experienced significant clinical regression.

Keratosis pilaris and variants

Christina M. Correnti, and Anna L. Grossberg

Keratosis pilaris (KP) is a common inherited disorder of unknown etiology characterized by tenacious keratin plugging of follicular orifices affecting characteristic body sites. It typically presents in childhood on the extensor aspects of the upper arms, anterior surfaces of the thighs, and lateral aspects of the cheeks. In more extensive cases, it may extend onto the distal extremities, shoulders, back, and

buttocks. Perifollicular erythema is common, and a background of erythema on the cheeks may also be seen in keratosis pilaris rubra (KPR). Other variants of KP include erythromelanos follicularis faciei et colli (EFFC) and keratosis pilaris atrophicans (KPA), which includes keratosis pilaris atrophicans faciei (ulerythema ophryogenes), keratosis follicularis spinulosa decalvans (KFSD), folliculitis spinulosa decalvans (FSD), and atrophoderma vermiculatum; these subtypes are also addressed in this chapter.

KP may be seen in conjunction with other skin disorders, such as atopic dermatitis; it may also arise or become exacerbated in association with various medical conditions or states, including pregnancy, and may be a feature of infants presenting with cutaneous stigmata of malnutrition. Extensive or persistent disease has also been observed in patients with Down syndrome and cardiofaciocutaneous syndrome, among others. KP has also developed in the setting of certain medications, notably Raf inhibitors.

Management Strategy

KP is very commonly asymptomatic and often does not require treatment. Those with extensive or symptomatic involvement often desire treatment, and even mild KP may cause patients cosmetic distress to the point of seeking therapy. It often becomes less prominent with increasing age, even without directed therapy.

Initial treatment aims to decrease excessive skin roughness and follicular accentuation. *Keratolytic agents* such as glycolic acid, ammonium lactate, salicylic acid, and urea-containing humectants are the mainstays of treatment. Use of a compound of salicylic acid 2% in 20% urea cream or salicylic acid 6% in propylene glycol combines the properties of an emollient with a keratolytic agent. Twice-daily application of one of these agents for at least a 3-week trial is recommended. The addition of gentle massage with a polyester sponge during a shower or bath may provide additional benefit. Vigorous scrubbing can lead to irritation and should be avoided. Once adequate relief of symptoms has been achieved, maintenance therapy of weekly or twice-weekly application of a topical keratolytic agent is recommended.

Topical retinoids may be utilized in some cases but must be gradually uptitrated in strength to avoid irritation. Tazarotene 0.05% cream has been shown to decrease the pruritus, erythema, and

roughness of KP in a recent placebo-controlled trial. *Oral isotretinoin* has been helpful in some patients with *ulerythema ophryogenes* and *atrophoderma vermiculatum*.

If a significant inflammatory component is present, the inflammation can be treated for defined short time periods with a *medium-potency topical corticosteroid* in an emollient base. Once inflammation has abated, corticosteroids should be discontinued, and treatment should transition to keratolytics.

Cutaneous laser and light therapies have been utilized for several variants of KP ([Table 124.1](#)).

Specific Investigations

- Consider serum testosterone levels in obese females
- Ophthalmologic examination in cases of *keratosis pilaris atrophicans*

The prevalence of cutaneous manifestations in young patients with type 1 diabetes

Pavlović MD, Milenković T, Dinić M, Misović M, Daković D, Todorović S, et al. *Diabetes Care* 2007; 30: 1964–7.

The presence and frequency of skin manifestations were examined and compared in 212 unselected type 1 diabetic patients and 196 healthy sex- and age-matched control subjects. KP affected 12% of the diabetic patients compared with 1.5% of control subjects.

Other conditions associated with KP include high body mass index, ichthyosis, atopic conditions, pregnancy, cardiofaciocutaneous syndrome, and hyperandrogenism in obese females. KP-like lesions have been observed in patients treated with vemurafenib for metastatic melanoma.

Keratosis pilaris atrophicans. One heterogeneous disease or a symptom in different clinical entities?

Oranje AP, van Osch LD, Oosterwijk JC. *Arch Dermatol* 1994; 130: 500–2.

Patients with *keratosis pilaris atrophicans* are reported to have increased incidence of ocular abnormalities, including photophobia, corneal deposits, juvenile cataracts, and corneal dystrophy.

This review also clarifies the confusing nosology of KP variants (ulerythema ophryogenes or KP atrophicans faciei, atrophoderma

vermiculatum, keratosis follicularis spinulosa, FSD).

Table 124.1

Cutaneous laser and light therapies in the treatment of keratosis pilaris (KP) and variants

Variant	Modality	Details
Keratosis pilaris spinulosa decalvans	Non-Q-switched, high-energy, pulsed ruby laser	One case of KPSD of the scalp was complicated by recurrent secondary infection with limited response to multiple oral antibiotics and topical corticosteroids. Five treatments with a normal mode, non-Q-switched, high-energy, pulsed ruby laser at fluences of 19–21 J/cm ² at 6-week intervals led to a significant reduction of inflammation in treated areas, at the expense of a persistent diminution of hair growth at 8-month follow-up. ^a
KP atrophicans (KPA)	585-nm pulsed-dye laser (PDL)	Twelve patients received two to eight treatments with energies ranging from 6.0–7.5 J/cm ² resulting in erythema improvement but not textural improvement. ^b
Keratosis rubra pilaris (KRP)	532-nm potassium titanyl phosphate laser	A fluence of 12–14 J/cm ² and pulse width of 510 ms was used for an initial seven treatments at 6- to 8-week intervals, then two treatments at 4-month intervals, resulting in cosmetic clearance of keratotic papules and reduction in facial erythema. ^c
KRP	595-nm PDL	Seven treatments spaced 6 weeks apart with spot size of 7 mm, a density energy up to 12 J/cm ² , and a pulse duration of 3 ms maintained marked improvement in erythema and follicular hyperkeratosis for 9 months. ^d
KPA	Intense pulsed light (IPL)	Four women were treated with five to nine sessions with an IPL system with a cut filter of 570 nm, power density between 40 and 47 J/cm ² divided into two pulses of 3 ms, with a delay between both of 20 ms, resulting in over 75% reduction in erythema, observed reduced roughness, and no recurrence after 10 months. ^e
KRP or KPA	PDL	Ten patients with either condition were treated with two to seven sessions using PDL of 595 nm, spot size of 7 or 10 mm, pulse duration of 0.5 or 1.5 ms, and a fluence from 5–9 J/cm ² , resulting in over 75% to total resolution of erythema, with one case of postinflammatory hyperpigmentation. ^f
KP	Q-switched 1064-nm Nd:YAG laser	Twelve patients with KP were treated with 10 sessions every 2 weeks at 4.0–5.0 J/cm ² , 4-mm spot size, for three passes, resulting in more than grade 2 improvements in skin texture and dyspigmentation. ^g
KP	Long-pulsed 1064-nm Nd:YAG laser	Eighteen patients with untreated KP were treated three times at 4-week intervals using a 30-msec pulse width and fluence of 34 J/cm ² , with the contralateral arm serving as a control, resulting in significant improvements in erythema and the number of keratotic papules. ^h
KP	Combination of 595-nm PDL, long-pulsed 755-nm alexandrite laser, and microdermabrasion	Twenty-nine sites in 26 patients with KP were treated using a combination therapy, including 595-nm PDL with nonpurpuragenic fluences, a long-pulsed 755-nm alexandrite laser, and microdermabrasion. Pretreatment and posttreatment photographs and patient satisfaction rates were compared 3 months after treatment: 41.4% of sites demonstrated grade 3 clinical improvement, 34.5% had grade 2 improvement, 13.8% had grade 1 improvement, and 10.3% had grade 4 improvement. Improvements were noted in erythema, skin texture, and brown

		discoloration. Prolonged scaling was a potential adverse event. ⁱ
KP	810-nm diode laser	Of 18 Fitzpatrick type I–III patients completing this randomized, split-body, placebo-controlled trial, 3 were lost to follow-up and 2 withdrew due to laser-induced postinflammatory hyperpigmentation. After three treatments spaced 4–5 weeks apart, two blinded dermatologists rated the sites at 12 weeks. Skin texture improved significantly, but baseline erythema was not improved. ^j

Red face revisited: disorders of hair growth and the pilosebaceous unit

Ramos-e-Silva M, Pirmez R. *Clin Dermatol* 2014; 32: 784–99.

This comprehensive review of diseases of the hair and pilosebaceous unit that may cause a red face includes epidemiology, clinical presentation, pathogenesis, and therapy of inflammatory follicular keratotic syndromes, ulerythema ophryogenes,

atrophoderma vermiculatum, KFSD, and FSD.

First-Line Therapies

• 10% lactic acid cream	B
• 5% salicylic acid cream	B
• Sodium lactate and urea cream	B
• Polyester sponge	D
• Salicylic acid in urea	D
• Topical corticosteroids	D

Epidermal permeability barrier in the treatment of keratosis pilaris

Kootiratrakarn T, Kampirapap K, Chunhasewee C. Dermatol Res Pract 2015; 2015: 205012.

A blinded, prospective, randomized, split-side trial of 50 KP patients compared twice-daily 10% lactic acid (LA) and 5% salicylic acid (SA) for 3 months of therapy and 4 weeks after completion. The mean reduction of the lesions from baseline was statistically significant for both 10% LA (66%) and 5% SA (52%), with LA being statistically more effective ($p > 0.05$).

The authors suggest LA be tried first, given faster improvement and greater efficacy, despite its potential side effect of mild localized skin irritation.

Evaluation of a sodium lactate and urea crème to ameliorate keratosis pilaris

Weber TM, Kowcz A, Rizer R. J Am Acad Dermatol 2004; 50 (Suppl 1): 47.

A formulation containing sodium lactate and urea was tested on 32

subjects with mild to severe KP. The authors reported progressive, statistically significant improvements in overall condition, skin roughness, and skin tone at 3, 6, and 12 weeks of use.

Practical management of widespread, atypical keratosis pilaris

Novick NL. J Am Acad Dermatol 1984; 11: 305–6.

Thirty patients with widespread atypical or psychologically troubling KP were treated for prevention of excessive skin drying with application of salicylic acid 2% to 3% in 20% urea cream using a polyester sponge and use of emollient-based topical corticosteroids if a prominent inflammatory component was present. All patients reported satisfaction with cosmetic results. Clearing of lesions was noted in 75% to 100% of cases, with elimination of most lesions achieved within 2 to 3 weeks of daily therapy.

Keratosis pilaris decalvans nonatrophicans

Drago F, Maietta G, Parodi A, Rebora A. Clin Exp Dermatol 1993; 18: 45–6.

This is the first case report of a patient with an eruption of keratosis pilaris decalvans nonatrophicans with follicular keratotic papules on the limbs and trunk and body hair loss without scarring. The patient was treated with emollients and multivitamins, and the eruption spontaneously cleared with hair regrowth after 3 months.

Traditional methods of treated KP seem to be effective in treating cases of keratosis pilaris decalvans.

Second-Line Therapies

• Topical tazarotene	A
• Topical tretinoin	D
• Isotretinoin	E
• Topical tacrolimus	A
• Aquaphor	A
• Dermabrasion (for atrophoderma vermiculatum)	E

A comparative trial comparing the efficacy of tacrolimus 0.1% ointment with Aquaphor ointment for the treatment of keratosis pilaris

Breithaupt AD, Alio A, Friedlander SF. *Pediatr Dermatol* 2011; 28: 459–60.

This was a bilateral, paired comparison, double-blind study that showed improvement but no difference between Aquaphor and tacrolimus 0.1% ointment in 27 patients.

Topical tacrolimus was more likely to lead to >75% improvement (six tacrolimus sites vs. one Aquaphor site), though this failed to reach statistical significance, likely due to small sample size.

Tazarotene 0.05% cream for the treatment of keratosis pilaris

Bogle MA, Ali A, Bartel H. *J Am Acad Dermatol* 2004; 50 (Suppl 1): 39.

A randomized, placebo-controlled, double-blind prospective study of tazarotene 0.05% cream for the treatment of KP on the posterior arms of 33 patients resulted in statistically significant improvement in pruritus, erythema, and roughness of KP lesions.

Natural history of keratosis pilaris

Poskitt L, Wilkinson JD. *Br J Dermatol* 1994; 130: 711–3.

This retrospective questionnaire study of 49 patients with KP yielded 14 patients who had benefited from a variety of treatments. Of these patients, 8 reported therapy with topical tretinoin cream to be helpful.

Two reported dramatic improvement with oral tetracyclines; however, the questionnaire did not permit exclusion of possible coincident acne.

Clinical findings, cutaneous pathology, and response to therapy in 21 patients with keratosis pilaris atrophicans

Baden HP, Byers HR. *Arch Dermatol* 1994; 130: 469–75.

Twenty-one patients with keratosis pilaris atrophicans were treated with various agents, including keratolytics, antibiotics, topical corticosteroids, and oral retinoids, all with very limited response. Treatment of four patients with isotretinoin 1 mg/kg resulted in little or no improvement in three patients and exacerbation of the condition in one patient.

A case of atrophoderma vermiculatum responding to isotretinoin

Weightman W. Clin Exp Dermatol 1998; 23: 89–91.

Atrophoderma vermiculatum is a rare variant of KP that results in reticular or honeycomb scarring of the face. In this case report, two 6-month therapeutic courses of 0.50 mg/kg/day of isotretinoin, 2 weeks apart, halted progression of further atrophy, and the patient remained free of new lesions after 1 year.

In severe cases of atrophoderma vermiculatum with significant scarring, a trial of isotretinoin therapy may be worthwhile to halt progression of the disease.

Atrophoderma vermiculatum. Case reports and review

Frosch PJ, Brumage MR, Schuster-Pavlovic C, Bersch A. J Am Acad Dermatol 1988; 18: 538–42.

Dermabrasion may be used to reduce eventual scarring.

A case of ulerythema ophryogenes responding to isotretinoin

Layton AM, Cunliffe WJ. Br J Dermatol 1993; 129: 645–6.

Ulerythema ophryogenes, a variant of KP, begins in the eyebrows as small, discrete, horny, pinhead-sized, follicular-based papules that spread to the forehead and scalp. Atrophy and alopecia of the eyebrows and scalp may result. There is a variable response to isotretinoin.

Third-Line Therapies

• Tetracyclines: oxytetracycline, minocycline	E
• Long-pulse, non-Q-switched, ruby laser (KP spinulosa decalvans)	E
• Dapsone (keratosis folliculitis decalvans)	E
• Pulsed tunable dye laser (KP atrophicans)	C
• Intense pulsed light (KP atrophicans)	E
• Potassium titanyl phosphate laser (keratosis rubra pilaris)	E
• Pulsed dye laser (keratosis rubra pilaris)	E
• Pulsed dye laser (KP or KP atrophicans faciei)	C
• Q-switched 1064-nm neodymium-doped yttrium aluminium garnet laser	C
• Long-pulsed 1064-nm neodymium-doped yttrium aluminium gamet laser	C
• 810-nm diode laser	C

Keratosis pilaris rubra: a common but underrecognized condition

Marqueling AL, Gilliam AE, Prendiville J, Zvulunov A, Antaya RJ, Sugarman J, et al. Arch Dermatol 2006; 142: 1611–6.

This series of 27 cases distinguishes the clinical presentation of KPR compared with EFFC and other overlapping variants of KP. EFFC is very similar to KPR, with follicular papules of the face and/or neck, except it tends to develop later in life, most frequently in the second decade, more commonly in males, and possesses the differentiating features of a lack of torso involvement and the presence of hyperpigmentation. Treatments given for KPR in these patients included emollients; urea, LA, SA, topical corticosteroids, or a combination of these ingredients; topical agents containing cholecalciferol; and topical or systemic retinoid agents. In most patients, there was no substantial improvement with these treatments. One patient had excellent response with pulsed dye laser (PDL).

Some authors consider KPR and EFFC to be forms of the same condition, whereas others have considered EFFC as a part of the KPA group.

Folliculitis spinulosa decalvans: successful therapy with dapsone

Kunte C, Loeser C, Wolff H. J Am Acad Dermatol 1998; 39: 891–3.

In this case report, a patient presented with FSD with keratotic follicular papules on the trunk and extremities; lateral eyebrow alopecia; and erythema, scaling, and follicular hyperkeratoses on the scalp. Isotretinoin and topical corticosteroids were ineffective. Dapsone (100 mg/day) led to the resolution of inflammation and pustulation on the scalp within 1 month. The scarring alopecia did not expand after dapsone therapy.

Complete eradication of chronic long standing eczema and keratosis pilaris following treatment with dextroamphetamine sulfate

Check JH, Chan S. Clin Exp Obstet Gynecol 2014; 41: 202–4.

Dextroamphetamine sulfate treatment for sympathetic nervous system hypofunction markedly improved chronic eczema in two patients as well as KP in one of the patients.

Eczema and KP are two more chronic dermatologic conditions, aside from chronic urticaria and prurigo nodularis, that may improve with dextroamphetamine sulfate treatment.

Photopneumatic therapy for the treatment of keratosis pilaris

Ciliberto H, Farshidi A, Berk D, Bayliss S. J Drugs Dermatol 2013; 12: 804–6.

In this small unblinded study of 10 patients, photopneumatic therapy improved both the erythema and redness associated with KP for at least 1 month after one treatment.

Dermatologic toxicities to targeted cancer therapy: shared clinical and histologic adverse skin reactions

Curry JL, Torres-Cabala CA, Kim KB, Tetzlaff MT, Duvic M, Tsai KY, et al. Int J Dermatol 2014; 53: 376–84.

In this review of published reports of dermatologic toxicities with multiple targeted cancer therapies, RAF inhibitors (vemurafenib and sorafenib) were associated with multiple cutaneous epithelial proliferations, including KP, seborrheic keratosis, verruca vulgaris, actinic keratosis, keratoacanthoma, and squamous cell carcinoma.

Langerhans cell histiocytosis

Catherine Borysiewicz, and Anthony C. Chu

Langerhans cell histiocytosis (LCH) is a reactive condition defined by the accumulation/proliferation of a clonal population of epidermal Langerhans cells. Recent studies showing mutation in cell proliferation/regulatory pathways, however, suggest that it should be

considered a neoplasm of myeloid origin. Patients can have either single or multiple organ involvement. Children tend to have more aggressive disease than adults.

LCH encompasses the diseases previously known as *histiocytosis X*, *eosinophilic granuloma*, *Hand–Schuller–Christian disease*, *Letter Siwe disease*, *congenital self-healing reticulohistiocytosis (Hashimoto–Pritzker)*, *Langerhans cell granulomatosis*, and *nonlipid reticuloendotheliosis*.

Management Strategy

Before institution of therapy, a full investigation must be completed. A definitive diagnosis can be made histologically by identification of Langerhans cells that express CD1a by immunohistochemistry and the finding of Birbeck granules by electron microscopy.

Treatment depends on the organ(s) involved and the severity of the disease and thus should be tailored to the individual patient. Most published data are based on case reports and small case series in children, and this evidence may not always be directly applicable to adults. Patients are staged as single system disease (with bone involvement, this is further stratified into monoostotic and polyostotic bone disease), multisystem disease, and multisystem disease with evidence of organ dysfunction. Although some patients with LCH may undergo spontaneous remission, the disease is unpredictable, and many patients progress from single system disease to multisystem disease. Organs most commonly involved include the bone, skin, lymph nodes, pituitary, liver, lungs, central nervous system, gastrointestinal tract, spleen, bone marrow, and endocrine system.

Single system bone or skin disease has a good prognosis and may not require treatment. *Curettage* or *intralesional steroid* injections can also be used in single system bone disease. Single system skin disease may respond to local measures with *topical steroids*, *topical nitrogen mustard*, *topical tacrolimus*, or *phototherapy*. Single system lung disease may respond to *prednisolone* at 2 mg/kg/day. In single system disease that does not respond to these measures, single system lymph node disease, and multisystem disease without organ dysfunction, systemic treatment with *azathioprine* (2 mg/kg/day), with or without low-dose, weekly *methotrexate* (5–10 mg/week), may lead to resolution.

In recalcitrant disease or in multisystem disease with evidence of organ dysfunction, treatment will depend on the age of the patient.

Organ dysfunction of key organs—liver, lungs, spleen, and bone marrow—carries the worst prognosis. Trials have demonstrated that in pediatric patients, *prednisolone with vinblastine* is the treatment of choice. This combination is less effective in adults, who are also more sensitive to their side effects. In adult patients, first-line treatment is *etoposide*. In pediatric studies the use of maintenance therapy has been shown to reduce the overall morbidity of the disease. Adults often have a more chronic and relapsing course to their disease, and maintenance therapy with *azathioprine* for 1 year should be considered in all patients with multisystem disease. In both children and adults with multisystem disease with organ dysfunction, there remains a small group who do not respond to conventional therapy. In these patients, *2-chlorodeoxyadenosine* has proved useful and, in severe disease, *bone marrow transplantation* has been successful. A number of drugs have been used in various stages of the disease, but most are anecdotal case reports.

There has been great interest in the last 4 years in the finding of BRAF V600E and MAP2K1 mutations in LCH, and this has led to treatment in a few patients with recalcitrant disease with vemurafenib.

Long-term morbidity can be correlated to organ involvement or occur as a direct consequence of treatment and includes skeletal deformities, risk of secondary malignancies (particularly with the use of alkylating agents and radiotherapy), endocrine dysfunction, and infertility.

Specific Investigations

Routine investigations

- Biopsy of organ involved for staining for S100 and CD1a or electron microscopy for Birbeck granules. The presence of Birbeck granules may also be demonstrated by immunohistochemical staining of langerin (CD207)
- Full blood count with differential
- Coagulation tests (prothrombin time [PT], activated partial thromboplastin time [APTT])
- ESR
- Liver function tests
- C-reactive protein

- Chest x-ray
- Whole body position emission tomography (PET) computed tomography (CT) is the most effective way to identify both skeletal and nonskeletal disease

Indicated investigations

- Lung function tests in patients with lung disease
- High-resolution CT chest for all adult smokers or children with chest signs or symptoms
- Bronchoalveolar lavage for CD1a + cells or open lung biopsy if evidence of lung involvement
- CT brain and pituitary fossa if signs of diabetes insipidus
- Plasma and urine osmolality if signs of diabetes insipidus (plus a water deprivation test, if required)
- Full hormone screen if diabetes insipidus confirmed
- Magnetic resonance imaging (MRI) brain if lytic skull lesions, diabetes insipidus, or symptoms suggestive of central nervous system (CNS) involvement
- Panorthogram if gum involvement
- Bone marrow biopsy if hematologic abnormalities
- Abdominal ultrasound and liver biopsy if abnormal liver function
- Multiple bowel biopsies if evidence of malabsorption or failure to thrive in an infant

Histiocytosis syndromes in children: approach to the clinical and laboratory evaluation of children with Langerhans cell histiocytosis

Broadbent V, Gadner H, Komp DM, Ladisch S. Med Pediatr Oncol 1989; 17: 492–5.

Multiple organ systems may be affected in patients with LCH. Therefore the following studies are recommended for all patients at diagnosis: a complete blood count with white blood cell differential, liver function tests, coagulation times (PT and PTT), chest radiograph, and radiographic skeletal survey (more sensitive than a radionuclide bone scan for detecting bone lesions). A measurement of urine osmolality after overnight water deprivation should also be obtained. Further evaluations should be tailored to patients based on specific presenting signs and symptoms.

BRAF V600E mutation correlates with suppressive tumour

immune microenvironment and reduces disease free survival in Langerhans cell histiocytosis

Zeng K, Wang Z, Ohshima K, Liu Y, Zhang W, Wang L, et al. Oncoimmunology 2016; 5: e1185582.

Study in 97 patients with LCH showed BRAF V600E mutation in 37.1% of patients, and this was significantly correlated with increased program cell death 1 ligand 1 (PDL1) expression and that BRAF V600E mutation and PDL1 were independent prognostic factors for disease survival in this disease.

BRAF V600E and MAP2K1 mutations in Langerhans cell histiocytosis occur predominantly in children

Zeng K, Ohshima K, Liu Y, Zhang W, Wang L, Fan L, et al. Hematol Oncol 2016; 10.1002/hon.2344 [Epub ahead of print].

Study in 97 patients with LCH showed BRAF V600E and MAP2K1 mutations in 32% and 17.5%, respectively. These mutations were significantly more common in children than in adults ($p = 0.001$).

First-Line Therapies

Skin disease

• Topical nitrogen mustard	C
• Phototherapy (PUVA, narrowband UVB)	E
• Topical tacrolimus	E

Multisystem disease

• Vinblastine	B
• Etoposide (VP16)	B

Topical nitrogen mustard: an effective treatment for cutaneous Langerhans cell histiocytosis

Sheehan MP, Atherton DJ, Broadbent V, Pritchard J. J Pediatr 1991; 119: 317–21.

Sixteen children with multisystem LCH with severe skin involvement were treated with topical nitrogen mustard with rapid clinical improvement. One child developed a contact allergy after use.

Long term follow up of topical mustine treatment for cutaneous Langerhans cell histiocytosis

Hoeger PH, Nanduri VR, Harper JI, Atherton DA, Pritchard J. Arch Dis Child 2000; 82: 483–7.

Topical nitrogen mustard (0.02% mechlorethamine hydrochloride mustard) was found to be safe in cutaneous disease. Follow-up in this study was an average of 8.3 years.

Topical nitrogen mustard ointment with occlusion for Langerhans' cell histiocytosis of the scalp

Treat JR, Suchin KR, James WD. J Dermatolog Treat 2003; 14: 46–7.

Topical nitrogen mustard ointment 0.01% under occlusion cleared a patient with scalp LCH in 3 weeks without irritation.

Topical nitrogen mustard in patients with Langerhans cell histiocytosis

Lindahl LM, Fenger-Gron M, Iversen L. Br J Dermatol 2012; 166: 642–5.

Ten children and four adults with skin involvement with LCH treated with nitrogen mustard and studied retrospectively. In five patients the skin improved, but in four patients systemic disease progressed; six patients developed contact dermatitis.

Topical nitrogen mustard is the best studied and most effective topical therapy. Contact allergy and risk of cutaneous carcinogenicity limit its use. It is not recommended for disease involving large areas of skin.

Satisfactory remission achieved by PUVA therapy in Langerhans cell histiocytosis in an elderly patient

Sakai H, Ibe M, Takaahashi H, Matsuo S, Okamoto K, Makino I, et al. J Dermatol 1996; 23: 42–6.

Case report of a 74-year-old man with cutaneous LCH and diabetes insipidus. Five weeks of PUVA therapy led to complete clearance of

skin lesions. The endocrinopathy persisted.

Cutaneous Langerhans cell histiocytosis in an elderly man successfully treated with narrowband ultraviolet B

Imafuku S, Shibata S, Tashiro A, Furue M. Br J Dermatol 2007; 157: 1277–9.

Doses of 0.4 J/cm² to 1.0 J/cm² were given incrementally (total irradiation of 9.3 J/cm²). Eleven sessions led to almost complete resolution in a Japanese man, which persisted at least 12 months after therapy was discontinued.

Etoposide in recurrent childhood Langerhans cell histiocytosis: an Italian cooperative study

Ceci A, De Terlizzi M, Colella R, Balducci D, Toma MG, Zurlo MG, et al. Cancer 1988; 62: 2528–31.

Twelve of 18 patients with recurrent LCH had a complete response and 3 a partial response after treatment with etoposide (200 mg/m²/day given 3 days every 3 weeks).

Langerhans cell histiocytosis in childhood: results from the Italian Cooperative AIEOP-CNR-H.X. '83 study

Ceci A, de Terlizzi M, Colella R, Loiacono G, Balducci D, Surico G, et al. Med Pediatr Oncol 1993; 21: 259–64.

Ninety patients were divided into those with and without organ dysfunction. Monotherapy with either vinblastine or etoposide was an effective treatment in patients without organ dysfunction.

A randomised trial of treatment for multisystem Langerhans' cell histiocytosis

Gadner H, Grois N, Arico M, Broadbent V, Ceci A, Jakobson A, et al. J Pediatr 2001; 138: 728–34.

This controlled trial of 24 weeks of vinblastine (6 mg/m², IV weekly) or etoposide (150 mg/m²/day for 3 days every 3 weeks) and an initial dose of methylprednisolone (30 mg/kg/day for 3 days) recruited 143 untreated children with multisystem LCH. The two treatments were found to be equally effective with response rates of 58% for vinblastine and 69% for etoposide. Vinblastine is considered safer for use in children.

Etoposide has been consistently shown to be effective in multifocal LCH. However, the small risk of secondary leukemia after treatment in children

with etoposide limits its use to the most high-risk pediatric patients.

Second-Line Therapies

• Prednisolone	B
• 6-Mercaptopurine	B
• Thalidomide	C
• Methotrexate	C
• Cytosine arabinoside (Ara-C)	C
• 2-Chlorodeoxyadenosine (2-CdA)	C

Improved outcome in multisystem Langerhans cell histiocytosis is associated with therapy intensification

Gadner H, Grois N, Pötschger U, Minkov M, Aricò M, Braier J, et al. Histiocyte Society. Blood 2008; 111: 2556–62.

This randomized controlled trial had 193 patients with multisystem disease. Arm A consisted of 4 weeks of prednisone 40 mg/m² once daily tapering over 2 weeks, vinblastine 6 mg/m² IV weekly for 6 weeks followed by 18 weeks of 6-mercaptopurine 50 mg/m² daily with vinblastine (6 mg/m²), and prednisolone (40 mg/m² for 5 days) pulses every 3 weeks; etoposide 150 mg/m² weekly for the first 6 weeks followed by pulsed therapy every 3 weeks was added in arm B. Both regimens had similar response rates (63% vs. 71%), 5-year survival probability (74% vs. 79%), and relapse rate (46% vs. 46%). *The more intense chemotherapy regimen with etoposide was better in patients with liver, lung, spleen, and hematopoietic system involvement.*

Treatment strategy for disseminated Langerhans cell histiocytosis

Gadner H, Heitger A, Grois N, Gatterer-Menz I, Ladisch S. Med

Pediatr Oncol 1994; 23: 72–80.

A study of 106 patients divided into three groups: group A (multifocal bone disease), group B (soft tissue disease without organ dysfunction), and group C (patients with organ dysfunction). All patients received 6 weeks of etoposide, vinblastine, and prednisone, followed by continuation therapy with 1 year of 6-mercaptopurine, vinblastine, and prednisone. Patients in group B also received etoposide during continuation therapy, and group C received both etoposide and methotrexate. A complete response was seen in 89% of group A, 91% of group B, and 67% of group C patients.

This study treated patients with 1 year of “maintenance” chemotherapy, which has not been shown to be superior to the use of intermittent treatment for disease exacerbations.

A case of adult Langerhans cell histiocytosis showing successfully regenerated osseous tissue of the skull after chemotherapy

Suzuki T, Izutsu K, Kako S, Ohta S, Hangaishi A, Kanda Y, et al. Int J Hematol 2008; 87: 284–8.

A case report of an adult with large osteolytic lesions in the skull that successfully responded to 6 weeks of prednisolone and vinblastine, followed by the addition of 6-mercaptopurine for a further 12 months. After treatment x-ray examination confirmed bone regeneration.

Successful treatment of cutaneous Langerhans cell histiocytosis with thalidomide

Sander CS, Kaatz M, Elsner P. Dermatology 2004; 208: 149–52.

Thalidomide 200 mg once daily was given to a 38-year-old male with recurrent mucocutaneous LCH. He had significant improvement within 4 weeks and complete healing after 3 months. Treatment was continued at 100 mg once daily without relapse.

Langerhans cell histiocytosis with vulvar involvement and responding to thalidomide therapy—case report

Fernandes LB, Guerra JG, Costa MB, Paiva IG, Duran FP, Jaco DN. An Bras Dermatol 2011; 86: S78–81.

A 57-year-old woman with extensive skin involvement, including the scalp, face, trunk, axillae, and vulva. Systemic steroids and thalidomide at 100 mg/day led to complete resolution after 4 months.

Disease relapsed on stopping treatment but was brought under control with thalidomide at 50 mg/day as maintenance therapy.

A phase II trial using thalidomide for Langerhans cell histiocytosis

McClain KL, Kozinetz CA. *Pediatr Blood Cancer* 2007; 48: 44–9.

Sixteen patients with LCH who had relapsed once or twice despite treatment were included in the trial. Six patients were considered high risk. The rest consisted of patients with skin and/or bone and/or brain involvement. Adults were commenced at 100 mg (children 50 mg) daily, which was increased by 50 mg per month until efficacy or toxicity was achieved. No high-risk patient responded to treatment. Four low-risk patients had complete responses, three had partial responses, and two did not respond.

Oral methotrexate and alternate-day prednisone for low-risk Langerhans cell histiocytosis

Womer RB, Anunciato KR, Chehrenama M. *Med Pediatr Oncol* 1995; 25: 70–3.

Thirteen low-risk children were treated successfully with prednisone 40 mg/m²/day on alternate days and weekly methotrexate 20 mg/m² for a minimum of 3 months. Toxicity was minimal, and recurrences were treated with the same regimen.

Cytosine-arabioside, vincristine, and prednisolone in the treatment of children with disseminated Langerhans cell histiocytosis with organ dysfunction: experience at a single institution

Egeler RM, de Kraker J, Voûte PA. *Med Pediatr Oncol* 1993; 21: 265–70.

Eighteen patients with multiorgan involvement (8 with organ dysfunction and 10 without organ dysfunction) received chemotherapy containing cytosine–arabioside, vincristine, and prednisolone. Sixty-three percent of patients with organ dysfunction and 80% without the organ dysfunction had sustained remission.

This regimen is well tolerated and avoids the risk of secondary malignancies associated with etoposide. Results compare satisfactorily with other chemotherapeutic regimens.

Successful treatment of Langerhans cell histiocytosis with 2-

chlorodeoxyadenosine

Goh NS, McDonald CE, MacGregor DP, Pretto JJ, Brodie GN. *Respirology* 2003; 8: 91–4.

A young man with LCH involving lungs and bone who had previously failed to respond to two chemotherapy regimens. Complete symptomatic remission was achieved after five cycles of 2-CdA (0.1 mg/kg/day for 7 days per cycle) with no evidence of recurrence at 5 years.

Efficacy of continuous infusion 2-CdA (cladribine) in pediatric patients with Langerhans cell histiocytosis

Stine KC, Saylor RL, Saccente S, McClaine KL, Becton DL. *Pediatr Blood Cancer* 2004; 43: 81–4.

Ten children with reactivated LCH or high-risk disease were treated with 2-CdA (initially 5 mg/m²/day for 3 days increasing to 6.5 mg/m²/day for 3 days). All 10 had clinical responses. Seven patients remained disease free for a median of 50 months. Three patients needed further drug therapy but were clinically in remission.

Cladribine (2-chlorodeoxyadenosine) in frontline chemotherapy for adult Langerhans cell histiocytosis: a single centre study of seven cases

Adam Z, Szturz P, Vanicek J, Moulis M, Pour L, Krejci M, et al. *Acta Oncol* 2013; 52: 994–1001.

Retrospective study of six males with multisystem disease and one male with multifocal bone disease treated with cladribine at 5 mg/m² subcutaneously in five cases or intravenously in two. Treatment was enhanced with cyclophosphamide and corticosteroids in two patients. Durable complete remissions were achieved in six patients with a median follow-up of 37 months. One patient had an early relapse.

This confirms the efficacy of 2-CdA in LCH, particularly in patients who have failed on other forms of treatment.

Third-Line Therapies

• Radiotherapy	B
• Ciclosporin	B
• Bone marrow transplantation	C
• Trimethoprim–sulfamethoxazole	C
• Vemurafenib	C
• Interferon- α	D
• 2-Deoxycoformycin	E
• Interleukin-2	E
• Isotretinoin	E
• Acitretin	E
• Lenalidomide	E
• Photodynamic therapy	E
• Clofarabine	E
• Mistletoe	E

Results of treatment of 127 patients with systemic histiocytosis (Letterer-Siwe syndrome, Schüller-Christian syndrome, and multifocal eosinophilic granuloma)

Greenberger JS, Crocker AC, Vawter G, Jaffe N, Cassady JR. *Medicine* 1981; 60: 311–38.

Many patients discussed in this retrospective study achieved

remission from local radiation therapy for bone and soft tissue lesions.

Chemotherapy is now generally preferred due to the slight risk of secondary malignancy, but also the fact that LCH is often a generalized disease and local treatment is thus limited.

Cyclosporin A therapy for multisystem Langerhans cell histiocytosis

Minkov M, Grois N, Broadbent V, Ceci A, Jakobson A, Ladisch S. Med Pediatr Oncol 1999; 33: 482–5.

Twenty-six patients with refractory LCH were treated with ciclosporin alone or in combination with prednisolone, vinblastine or etoposide, and/or antithymocyte globulin. The median dose was 6 mg/kg/day (range 2–12 mg/kg/day) for a median duration of 4.5 months. One patient had a complete response, and three had a partial response.

Ciclosporin has been effective in only a small number of patients with LCH, and remissions tend to be short.

Hematopoietic stem cell transplantation in patients with severe Langerhans cell histiocytosis and hematological dysfunction: experience of the French Langerhans Cell Study Group

Akkari V, Donadieu J, Piguet C, Bordigoni P, Michel G, Blanche S, et al. Bone Marrow Transpl 2003; 31: 1097–103.

Eight patients with LCH and hematologic dysfunction received a hematopoietic stem cell transplant (three autologous and five allogeneic). All had responded poorly to initial chemotherapy. Autologous transplant failed in all patients. Three patients had a complete response, and two died from toxicity after the allogeneic transplant. Ultimately only two patients had no recurrences after 21 months and 7 years of follow-up.

Improved outcome of treatment resistant high risk Langerhans cell histiocytosis after allogeneic stem cell transplantation with reduced-intensity conditioning

Steiner M, Matthes Martin S, Attarbaschi A, Minkov M, Grois N, Unker E, et al. Bone Marrow Transpl 2005; 36: 215–25.

Treatment-related mortality after hematopoietic stem cell transplant for multisystem refractory LCH is unacceptably high (50%). Therefore a novel approach is to use a reduced intensity

conditioning (RIC) protocol. Nine patients with multisystem-risk, organ-positive LCH who had active disease despite numerous therapies underwent RIC allogeneic stem cell transplant; 78% (seven of nine) were alive without evidence of disease after 1 year. Two patients died.

Stem cell transplant for refractory LCH can be highly toxic but can achieve sustained disease control. Several other case reports have documented long-term remissions after bone marrow transplantation. This approach is generally reserved for patients with fulminant disease not responding to chemotherapy.

Effect of trimethoprim-sulphamethoxazole in Langerhans cell histiocytosis: preliminary observations

Tzortzatou-Stathopoulou F, Xaidara A, Mikraki V, Moschovi M, Arvantis D, Ageloyianni P, et al. *Med Pediatr Oncol* 1995; 25: 74–8.

Twenty-three children with both single and multisystem disease were treated for a 4-week to 3-month duration. Patients with single system disease responded well, whereas those with multisystem disease had a more limited response.

Dramatic efficacy of vemurafenib in both multisystemic and refractory Erdheim Chester disease and Langerhans cell histiocytosis harboring the BRAF V600E mutation

Haroche J, Cohen-Aubart F, Emile JF, Arnaud L, Maksud P, Charlotte F, et al. *Blood* 2013; 121: 1495–500.

Two patients with skin or lymph node LCH showing BRAF V600E mutation were treated with vemurafenib for 4 months. Patients responded, but persistent active disease was still observed.

Widespread skin-limited Langerhans cell histiocytosis: complete remission with interferon alpha

Kwong YL, Chan ACL, Chan TK. *J Am Acad Dermatol* 1997; 36: 628–9.

Subcutaneous interferon- α at 6 MU daily for 9 months followed by 3 MU for 9 months led to resolution of a patient with extensive single system cutaneous disease.

Intralesional interferon- α has been used for localized cutaneous disease also.

Successful treatment of two children with Langerhans' cell

histiocytosis with 2'-deoxycoformycin

McCowage GB, Frush DP, Kurtzberg J. *J Pediatr Hematol Oncol* 1996; 18: 154–8.

Two patients (aged 3 and 5) who were refractory to multiple chemotherapeutic agents were treated with 2'-deoxycoformycin 4 mg/m² intravenously weekly for 8 weeks, then every 2 weeks for at least 16 months. Both patients achieved sustained remission with continued treatment. Toxicity was limited to asymptomatic grade III to IV lymphopenia and abnormalities of lymphocyte mitogen responses.

Interleukin-2 therapy of Langerhans cell histiocytosis

Hirose M, Saito S, Yoshimoto T, Kuroda Y. *Acta Pediatr* 1995; 84: 1204–6.

A 20-month-old girl with disseminated LCH who had failed chemotherapy achieved a transient remission with intravenous IL-2.

Langerhans cell histiocytosis: complete remission after oral isotretinoin therapy

Tsambaos D, Georgiou S, Kapranos N, Monastirli A, Stratigos A, Berger H. *Acta Derm Venereol* 1995; 75: 62–4.

A patient with single system cutaneous disease achieved a complete response to oral isotretinoin at 1.5 mg/kg/day for 9 months with no relapse at 5 years.

Langerhans cell histiocytosis in an adult: good response of cutaneous lesions to acitretin

Cardoso JC, Cravo M, Cardosos R, Brites MM, Reis JP, Tellechea O, et al. *Clin Exp Dermatol* 2010; 35: 627–30.

Erosive LCH in the groin was treated with acitretin 25 mg/day and topical steroids. After 1 year the patient was free of skin lesions and treatment was stopped. No follow-up was documented.

Lenalidomide induced therapeutic response in a patient with aggressive multi-system Langerhans cell histiocytosis resistant to 2-chlorodeoxyadenosine and early relapse after high dose BEAM chemotherapy with autologous peripheral stem cell transplant

Adam Z, Rehak Z, Koukalova R, Szturz P, Krejci M, Pour L, et al. *Vnitr Lek* 2012; 58: 62–71.

An adult patient with multisystem LCH had relapsed after treatment with a combination of etoposide and cyclophosphamide, then cladribine, and then BEAM chemotherapy (carmustine, etoposide, cytarabine, melphalan) with autologous stem cell transplant. Treatment was started with lenalidomide 25 mg/day for 21 days in 28-day cycles. After four cycles, 50% reduction in size of lymph nodes was noted on imaging. With further cycles, etoposide 100 mg on days 22, 23, and 24 was added. After five cycles, complete remission was achieved, and the patient underwent allogeneic bone marrow transplant 4 months later.

Photodynamic therapy for multi-resistant cutaneous Langerhans cell histiocytosis

Failla V, Wauters O, Caucanas M, Nikkels-Tassoudji N, Nikkels AF. *Rare Tumours* 2010; 2: e34.

An 18-month-old boy with severe skin involvement failed to respond to topical steroids and topical nitrogen mustard. Systemic corticosteroids and vinblastine improved the trunk, but not the scalp. Methyl aminolevulinate-based photodynamic therapy resulted in significant regression of the scalp lesions. Follow-up for 6 months showed no recurrence.

Clofarabine in refractory Langerhans cell histiocytosis

Rodriguez-Galindo C, Jeng M, Khuu P, McCarville MB, Jeha S. *Pediatr Blood Cancer* 2008; 51: 703–6.

Two children with LCH refractory to treatment (including 2-CdA) were treated with five or six cycles of clofarabine (optimized to 25 mg/m²/day for 5 days), which induced remission in both patients.

Response to subcutaneous therapy with mistletoe in recurrent multisystem Langerhans cell histiocytosis

Seifert G, Laengler A, Tautz C, Seeger K, Henze G. *Pediatr Blood Cancer* 2007; 48: 591–2.

A patient with multisystem disease, recurrent relapses, and persistent cutaneous lesions, despite chemotherapy, was treated with an aqueous extract of mistletoe (Helixor) subcutaneously three times a week, alternating doses weekly between 1 mg, 2.5 mg, and 5 mg. Cutaneous lesions cleared after 4 weeks of treatment, and the patient remained in remission after 5 years on continuous treatment.

Leg ulcers

David J. Margolis

Chronic leg wounds are likely related to the fact that legs are on the most distal aspects of the circulatory, lymphatic, and nervous system supply, in addition to the fact that the legs are the bearers of weight and gravity. Arterial and venous problems, infection, trauma, and systemic problems such as diabetes add to impaired healing. Leg ulcers secondary to other causes such as infection, keratinocyte cancers, or pyoderma gangrenosum are discussed elsewhere.

Management of leg ulcers is at least partially based on the etiology of the wound.

Management Strategy

Wound care

Many chronic wounds are contaminated by microorganisms, but most are likely not infected. It is generally believed that *debridement* is the first step toward treating wound contamination. The presence of microorganisms and necrotic tissue causes local tissue inflammation resulting in high levels of proinflammatory cytokines and tissue proteases. Debridement and aggressive cleaning can be done mechanically with curettage, scissors, or scalpel. It can also be accomplished with pressurized liquids, ultrasound, biomechanically (i.e., maggots), and enzymatically.

Dressing

Wound dressings should be chosen to address exudate control, wound protection, and pain relief. The goal is to provide a moist wound environment to promote granulation tissue formation and epithelialization. Using *hydrocolloids, hydrogels, alginates, transparent films*, and other bandages provides coverage and may promote the function of these enzymes. However, excessive exudate can saturate the wound bed, diminishing these beneficial properties, and macerate surrounding tissue, making it more prone to injury. Finally, choosing a dressing that does not adhere to the wound bed can be important to assure that it does not disrupt reepithelialization when it is removed.

Accurately identifying the key cause of wounds is essential in the management of leg ulcers though many wounds are complex and may be of more than one etiology. The following are specific approaches to different leg ulcers.

Venous leg ulcers

Venous insufficiency caused by venous reflux and/or deep venous thrombosis (DVT) is a cause of ambulatory venous hypertension, which leads to venous leg ulcers. The diagnosis of superficial or deep venous abnormality can be with a duplex ultrasound but may also be

apparent on clinical examination.

Calf muscle pump function is critical for venous outflow; thus venous ulcer management hinges on good lower limb compression. The use of *compression bandages* for venous leg ulcers has been carefully studied and is the standard care. For prevention, it is recommended that patients wear graduated *compression stockings*. *Leg elevation and weight reduction* reduce swelling severity.

Arterial ulcers

Ulcers can be caused by chronic limb ischemia, usually the result of peripheral vessel disease. Those with diabetes tend to have involvement of smaller arterioles. Lower limb ischemia causes pain and limb pallor. Arterial circulation can be evaluated noninvasively with ankle brachial index (ABI) and pulse volume recordings (PVR). The PVR may be nondiagnostic in patients with advanced calcification such as those with diabetes. In this setting a duplex ultrasound or computed tomography (CT) angiography is necessary. Treatment including proximal obstructive lesions causing ischemia may require invasive interventions such as *angioplasty* or *arterial bypass grafting*. Patients with poor arterial circulation can develop deep soft tissue infection, osteomyelitis, or gangrene, leading to amputation.

Diabetic neuropathy

Unperceived trauma and/or pressures can lead to wounding and ulcer formation in diabetic neuropathy. A 5.07 Semmes–Weinstein monofilament can be used to test for protective sensation.

Pressure ulcers

Pressure ulcers most often occur in patients with limited mobility, such as bed-ridden elderly patients or those with spine or brain injury, and are most commonly seen in areas bearing weight from sitting or lying over a bony prominence close to the surface of the skin, such as the sacrum or trochanter. Efforts should be aimed at off-loading the affected area.

First-Line Therapies

- Depending on wound etiology (e.g., surgical revascularization, compression therapy, and/or off-loading)
- Debridement of devitalized tissue and antibiotics (often not necessary)
- Wound dressings to maximize the wound environment depending on the wound setting

Chronic venous ulcers: a comparative effectiveness review of treatment modalities

Zenilman J, Valle MF, Malas MB, Maruthur N, Qazi U, Suh Y, et al. Comparative Effectiveness Review No. 127. AHRQ Publication No. 13-EHC121-EF. Rockville, MD: Agency for Healthcare Research and Quality. December 2013.

General evidence-based review on the therapy for venous leg ulcers.

Compression for venous leg ulcers

O'Meara S, Cullum NA, Nelson EA. Cochrane Database Syst Rev 2012; 11: CD000265.

Compression increases ulcer healing rates compared with no compression.

Antibiotics and antiseptics for venous leg ulcers

O'Meara S, Al-Kurdi D, Ologun Y, Ovington LG. Cochrane Database Syst Rev 2010; 1: CD003557.

No evidence supports routine use of systemic antibiotics. However, lack of evidence does not mean that it is ill advised.

Recommendations are that antibacterial preparations should only be used in clinical infections.

Compression for preventing recurrence of venous ulcers

Nelson EA, Bell-Syer SEM. Cochrane Database Syst Rev 2015; 9: CD002303.

Evidence from one trial exists that compression hosiery reduces the rate of reulceration among those with venous leg ulcers.

Diabetes, lower extremity amputation and death

Hoffstad O, Mitra N, Walsh J, Margolis DJ. Diabetes Care 2015; 38:

1852–7.

Individuals with diabetes and a lower extremity amputation are nearly three times more likely to die at any given point in time than those with diabetes who do not have an amputation. The cause of death is only partially explained by known complications of diabetes.

Second-Line Therapies

- Ablation of incompetent superficial and perforator veins for venous leg ulcers
- Cell-based therapy (e.g., living or nonviable allografts)
- Device-based therapy (e.g., hyperbaric oxygen, negative pressure therapy, etc.)
- Systemic therapy (e.g., pentoxifylline, etc.)

The impact of ablation of incompetent superficial and perforator veins on ulcer healing rates

Harlander-Locke M, Lawrence PF, Alktaifi A, Jimenez JC, Rigberg D, DeRubertis B. *J Vasc Surg* 2012; 55: 458–64.

Significant reduction in ulcer size and ultimate healing after ablation of incompetent superficial and perforator veins in patients who have failed conventional compression therapy.

A factorial, randomized trial of pentoxifylline or placebo, four-layer or single-layer compression, and knitted viscose or hydrocolloid dressings for venous ulcers

Nelson EA, Prescott RJ, Harper DR, Gibson B, Brown D, Ruckley CV. *J Vasc Surg* 2007; 45: 134–41.

Pentoxifylline increased the proportion of healing compared with placebo.

Hyperbaric oxygen therapy for chronic wounds

Kranke P, Bennett MH, Martyn-St James M, Schnabel A, Debus SE. *Cochrane Database Syst Rev* 2015; 6: CD004123.

Hyperbaric oxygen therapy may improve the healing of diabetic foot ulcers in the short term but not the long term.

Hyperbaric oxygen therapy does not reduce indications for amputation in patients with diabetes with nonhealing ulcers of

the lower limb: a prospective, double blinded, randomized controlled clinical trial

Fedorko L, Bowen JM, Jones W, Oreopoulos G, Goeree R, Hopkins RB, et al. *Diabetes Care* 2016; 39: 392–9.

A randomized clinical trial that did not demonstrate an advantage of hyperbaric oxygen therapy when added to comprehensive wound care for the treatment of a chronic diabetic foot ulcer.

Skin grafting and tissue replacement for treating foot ulcers in people with diabetes

Santema TB, Poyck PPC, Ubbink DT. *Cochrane Database Syst Rev* 2016; 2: CD011255.

Diabetic foot ulcers may benefit from the use of skin grafts and tissue replacements.

Advanced wound care therapies for nonhealing diabetic, venous and arterial ulcers

Greer N, Foman NA, MacDonald R, Dorrian J, Fitzgerald P, Rutks I, et al. *Ann Intern Med* 2013; 159: 532–42.

Advanced therapies can improve the likelihood that an individual with a nonhealing wound will heal.

Stem cells in wound healing: the future of regenerative medicine? A minireview

Duscher D, Wond VW, Maan ZN, Whittam AJ, Januszyk M, Gurtner GC. *Gerontology* 2016; 62: 216–25.

Review describing evidence to date on the use of stem cells for the treatment of chronic wounds and the challenges of conducting studies to show the clinical usefulness of this therapy.

Comparative effectiveness of a bioengineered living cellular construct vs. a dehydrated human amniotic membrane allograft for the treatment of diabetic foot ulcers in a real world setting

Kirsner RS, Sabolinski ML, Parsons NB, Skornicki M, Marston WA. *Wound Repair Regen* 2015; 23: 737–44.

An electronic medical records database cohort study comparing two advanced therapies. Both therapies appeared to be effective, although the living cellular construct was superior.

The use of human amnion/chorion membrane in the clinical

setting of lower extremity repair: a review

Zelen CM, Snyder RJ, Serena TE, Li WW. Clin Podiatr Med Surg 2015; 32: 135–46.

A summary of several studies on the use of amniotic-based products to improve wound outcomes.

Leiomyoma

Nick Collier, and Ian Coulson

Courtesy of Joseph Bikowski, MD.

Cutaneous leiomyomas are rare benign neoplasms originating from smooth muscle. Three types exist: (1) piloleiomyoma, the most common type, arising from the arrectores pilorum muscle; (2) dartoid myoma, or genital leiomyoma, arising from scrotal/labial dartos muscle or smooth muscle of the nipple; and (3) angioleiomyoma, arising from vascular wall muscle. Piloleiomyomas frequently occur as multiple lesions (80%). Multiple leiomyomas can be inherited in an autosomal dominant fashion in association with uterine leiomyoma (Reed syndrome, *multiple cutaneous and uterine leiomyomata* [MCUL1; OMIM [150800](#)]). Familial multiple leiomyomata can rarely be associated with renal cell cancer (*hereditary leiomyomatosis and*

renal cell cancer [HLRCC; OMIM [605839](#)]). Both familial forms are caused by mutations in the fumarate hydratase gene (coding for an enzyme in the tricarboxylic acid cycle) on 1q42.1, which is hypothesized to act as a tumor suppressor gene through an unknown mechanism. Clinically, cutaneous leiomyomas present as flesh-colored or brownish-red dermal papules or nodules up to 2 cm in diameter, typically distributed on the trunk and extensor surfaces of extremities. They often appear from the second to fourth decade and gradually increase in number and size. Paroxysmal pain, described as stabbing, burning, or pinching, may be triggered by cold or mechanical stimulation and is possibly due to muscle contraction or compression of entrapped nerves. Angioleiomyomas are less frequently symptomatic, whereas genital leiomyomas are asymptomatic.

Management Strategy

Symptomatic solitary lesions are best *excised*. Symptomatic multiple leiomyomas are therapeutically challenging because they involve a large area and recur after excision in 50% of cases. Selective excision of larger painful lesions may be considered, provided patients are warned of the relatively high chance of recurrence. CO_2 laser ablation of symptomatic lesions may be successful. Other therapeutic methods aim to inhibit smooth muscle contraction, and thus pain, by interfering with local tissue mediators (e.g., norepinephrine, epinephrine, and acetylcholine). There are reports of success with oral *doxazosin* (a selective α_1 -blocker) 1 to 4 mg daily, oral *nifedipine* (calcium channel blocker) 10 mg three times daily, *amlodipine* (calcium channel blocker) 5 mg twice daily, *phenoxybenzamine* (nonselective α -blocker) 10 mg twice daily, topical 9% *hyoscine hydrobromide* (anticholinergic), and oral *glyceryl trinitrate* (nitroglycerin) 0.8 to 1.6 mg as needed. Analgesics that target neuropathic pain, for example, oral *gabapentin* 300 mg three times daily and *duloxetine*, have been beneficial. Potential triggers should be avoided. Intralesional injection of *botulinum toxin A* (5 units per cm^2) has shown some benefit.

Women, particularly those with a family history, should undergo gynecologic review to exclude possible uterine involvement (“fibroids”). Menorrhagia may necessitate hysterectomy, and leiomyosarcoma, although rare, should be excluded. Potential familial

forms require referral to a clinical geneticist with informed consent for mutational analysis of the fumarate hydratase gene. Individuals considered to have HLRCC will require renal ultrasound surveillance to detect the development of renal tumors.

Specific Investigations

- Biopsy
- Biochemical assay of fumarate hydratase – for low/absent activity
- Genetic analysis – for fumarate hydratase gene mutations

Cutaneous smooth muscle neoplasms: clinical features, histologic findings and treatment options

Holst VA, Junkins-Hopkins JM, Elenitas R. J Am Acad Dermatol 2002; 46: 477–90.

A well-referenced review covering leiomyoma and angioleiomyoma. On histologic examination, leiomyomas stained with special stains such as Masson trichrome reveal brick-red smooth muscle fibers. Immunohistochemical techniques demonstrating desmin, smooth muscle actin, or muscle-specific actin confirm tumor origin.

Germline mutations in FH predispose to dominantly inherited uterine fibroids, skin leiomyomata and papillary renal cell cancer

Tomlinson IP, Alam NA, Rowan AJ, Barclay E, Jaeger EE, Kelsell D, et al. Multiple Leiomyoma Consortium. Nature Genet 2002; 30: 406–10.

The authors demonstrate that the gene predisposing to uterine fibroids, cutaneous leiomyoma, and renal cell carcinoma encodes fumarate hydratase. This enzyme acts as a tumor suppressor in familial leiomyomas, and its measured activity in the tumor is very low or absent. Mutations of the fumarate hydratase gene are found in individuals with dominantly inherited susceptibilities to multiple cutaneous and uterine leiomyomatosis and renal cancer.

Evidence for a new fumarate hydratase gene mutation in a unilateral type 2 segmental leiomyomatosis

Parmentier L, Tomlinson I, Happle R, Borradori L. Dermatology 2010; 221: 149–53.

A novel mutation, c.695delG, leading to a truncated protein,

p.Gly232AspfsX24, was found.

First-Line Therapy

• Surgical excision	D
---------------------	----------

Leiomyomas of the skin

Fisher WC, Helwig EB. Arch Dermatol 1963; 88: 510–20.

The clinical findings and natural course of 54 cutaneous leiomyomas from 38 patients are described. Surgically excised leiomyomas were found to have a high recurrence rate of 50%.

Second-Line Therapies

• Doxazosin	E
• Phenoxybenzamine	E
• Topical hyoscine hydrobromide	E
• Nifedipine	E
• Amlodipine	E
• Oral glyceryl trinitrate	E
• Cryotherapy	E
• Simple analgesics	E
• Gabapentin	E
• Duloxetine	E
• Botulinum toxin A	E
• CO ₂ laser	E

The rarity of the condition means that most publications on therapy are case reports. The therapeutic agents are not consistently effective.

Successful treatment of pain in two patients with cutaneous leiomyomata with the oral alpha-1 adrenoceptor antagonist, doxazosin

Batchelor RJ, Lyon CC, Highet AS. Br J Dermatol 2004; 150: 775–6.

Two women with symptomatic cutaneous leiomyoma were treated with oral doxazosin 1 to 4 mg daily, a reversible α_1 -blocker that, unlike phenoxybenzamine, is selective. Doxazosin was well tolerated,

and patients experienced “dramatic improvement”/complete relief of symptoms that was sustained for 6 months in one patient.

Pharmacologic modulation of cold-induced pain in cutaneous leiomyomata

Archer CB, Whittaker S, Greaves MW. *Br J Dermatol* 1988; 118: 255–60.

Two cases of cutaneous leiomyoma. One patient responded only to phenoxybenzamine 10 mg twice daily, and the other responded to hyoscine hydrobromide (the response lasted only 6 hours). The latter patient also improved with cryotherapy.

Therapy for painful cutaneous leiomyomas

Thompson JA. *J Am Acad Dermatol* 1985; 13: 865–7.

A 24-year-old man with multiple painful leiomyomas treated successfully with nifedipine 10 mg three times daily for 8 months. The dosage was increased to 10 mg four times daily after the onset of cool weather and increased pain.

Leiomyomatosis cutis et uteri

Engelke H, Christophers E. *Acta Derm Venereol* 1979; 59: 51–4.

A woman with cutaneous leiomyoma who responded to oral glyceryl trinitrate 0.8 to 1.6 mg for acute attacks, with maintenance nifedipine 20 mg and phenoxybenzamine 60 mg administered during 2 years of follow-up.

Disseminated cutaneous leiomyomatosis treated with oral amlodipine

Aggarwal S, De D, Kanwar AJ, Saikia UN, Khullar G, Mahajan R. *Indian J Dermatol Venereol Leprol* 2013; 79: 136.

A 32-year-old male with multiple painful cutaneous leiomyomas, who was intolerant of nifedipine due to headaches, experienced significant pain reduction and reduced side effects using amlodipine.

Gabapentin treatment of multiple piloleiomyoma-related pain

Alam M, Rabinowitz AD, Engler DE. *J Am Acad Dermatol* 2002; 46: S27–9.

A 54-year-old woman with numerous cutaneous leiomyomas who experienced near-complete pain relief with gabapentin 300 mg three times daily introduced gradually.

Successful pain relief of cutaneous leiomyomata due to Reed syndrome with the combination treatment of pregabalin and duloxetine

Kostopanagiotou G, Arvaniti C, Kitsiou MC, Apostolaki S, Chatzimichael K, Matsota P. *J Pain Symptom Manage* 2009; 38: e3–5.

A combination of pregabalin 600 mg daily and duloxetine 60 mg daily was used successfully to treat a 34-year-old woman with multiple leiomyomas. This produced complete pain relief that was maintained over a 12-month follow-up period.

Efficacy of intralesional botulinum toxin A for treatment of painful cutaneous leiomyomas: a randomized clinical trial

Naik HB, Steinberg SM, Middelton LA, Hewitt SM, Zuo RC, Linehan WM, et al. *JAMA Dermatol* 2015; 151: 1096–102.

Eighteen participants received either placebo or 5 units per cm² of botulinum toxin A. There was a 4-point fall in the skin-related Dermatology Life Quality Index (DLQI). There was a reduction in resting leiomyoma-related pain but not after ice provocation.

Treatment of multiple cutaneous leiomyomas with CO₂ laser ablation

Christenson LJ, Smith K, Arpey CJ. *Dermatol Surg* 2000; 26: 319–22.

A 73-year-old woman not eligible for pharmacologic therapy who had multiple cutaneous leiomyomas. CO₂ laser ablation of six symptomatic cutaneous leiomyomas induced complete pain relief that was sustained during 9 months of follow-up.

Successful treatment of multiple cutaneous leiomyomas with carbon dioxide laser ablation

Michajłowski I, Błażewicz I, Karpinsky G, Sobjanek M, Nowicki R. *Postepy Dermatol Alergol* 2015; 32: 480–11.

Leiomyomas over the deltoid were treated with CO₂ laser ablation, with each lesion being treated on four occasions at monthly intervals. The cosmetic result was suboptimal, but pain was greatly diminished.

Leishmaniasis

Suhail M. Hadi, and Ali S. Hadi

Courtesy of Joseph Bikowski, MD.

Leishmaniasis is a flagellate protozoan disease caused by many species of the genus *Leishmania*. It can be classified into three clinical forms: visceral (kala azar), which is the most severe form; mucocutaneous, which may lead to extensive destruction of the

mucous membranes; and cutaneous (Old and New World), which affects mainly exposed parts of the body, causing ulcers and eventually scarring.

Generalized and mucosal leishmaniasis may be seen in patients with human immunodeficiency virus (HIV) infection and acquired immune deficiency syndrome (AIDS). Subclinical forms of the disease do exist. Leishmaniasis is transmitted mainly by the bite of the infected female phlebotomine sandfly. However, other possible routes of transmission exist, including transfusion, needle sharing, congenital, sexual, and person-to-person contact. Only the management of cutaneous leishmaniasis (CL) will be addressed here.

Many faces of cutaneous leishmaniasis

Bari AU, Rahman SB. Indian J Dermatol Venereol Leprol 2008; 74: 23–7.

A total of 718 patients with CL were analyzed; 5.7% had unusual presentations. The most common of these presentations was lupoid leishmaniasis.

Cutaneous leishmaniasis mimicking inflammatory and neoplastic processes: a clinical, histopathological and molecular study of 57 cases

Saab J, Fedda F, Khattab R, Yahya L, Loya A, Satti M, et al. J Cutan Pathol 2012; 39: 251–62.

Skin biopsies from 145 patients were studied; 125 were confirmed as CL by polymerase chain reaction (PCR). Eighteen cases presented with a prebiopsy clinical diagnosis that ranged from dermatitis to neoplasm. Of the 125 cases, 57 showed a histopathologic pattern other than CL.

Management Strategy

CL presents with a typical lesion and a history of exposure. A skin scraping for microscopic analysis is the simplest test. Cultures from an exudate or scraping show good results. PCR offers a rapid, highly sensitive, and specific modality of diagnosis. Serologic tests can be used and include the indirect immunofluorescent antibody test, direct agglutination test, fast agglutination screening test, and enzyme-linked immunosorbent assay (ELISA).

A new vaccine has been recently studied for its protection against CL. Results showed durable protective immunity. It has the advantages of being inexpensive and administered by a noninvasive nasal route.

Pentavalent antimonials are the first-line therapy. *Meglumine antimoniate* is the drug of choice. It can be given intralesionally with local anesthetic (particularly in children, because of pain) or systemically 10 mg/kg daily for 2 weeks. *Leishmania recidivans* requires higher doses for longer periods. *Sodium stibogluconate* can be infiltrated into individual lesions 1 to 2 mL/week. In widespread severe cases it can be given intramuscularly or intravenously in a dose of 10 mg/kg/day for 2 weeks.

Pentavalent antimoniate use is complicated by a high rate of side effects, including arthralgia; fatigue; gastrointestinal (GI) upset; elevation of amylase, lipase, and liver enzyme levels; leukopenia; anemia; and electrocardiogram (ECG) abnormalities. Side effects appear to be dose related and are more common in patients with renal and liver impairment and those with cardiac arrhythmias.

Amphotericin B has been used in antimony-resistant cases.

Pentamidine isethionate (aromatic diamidine) is effective for diffuse CL. Side effects of pentamidine include hypoglycemia, diabetes mellitus, hypotension (if administered too rapidly), GI upset, and headache.

Allopurinol has antileishmanial activity, and other oral drugs such as miltefosine, zinc sulfate, rifampin, doxycycline, and azoles are also beneficial. γ -Interferon was shown to be effective as monotherapy treatment. Topical preparations such as *paromomycin* ointment and 5% *imiquimod* show considerable therapeutic potential.

Good cure rates have been achieved with both thermotherapy and cryotherapy. Lasers have been used, but further studies are needed to support their benefit. Additional treatment modalities are presented next.

Specific Investigations

- Skin biopsy
- Fine needle aspiration
- Slit-skin smear, press imprint smear
- Culture

- Leishmanin (Montenegro) skin test
- Serology
- Polymerase chain reaction (PCR) for leishmanial deoxyribonucleic acid (DNA)

The margin of the lesion contains amastigotes, whereas the center has dead skin and debris. Accordingly, the margin is preferred when performing a slit-skin smear. The aspirate can then be sent for culture or histology, which shows Leishman–Donovan bodies inside macrophages using Giemsa stain.

The gold- standard medium for culture is Novy–MacNeal–Nicolle, with positive results in 1 to 3 weeks, or Schneider *Drosophila* medium, which gives positive results in 1 week.

Microculture is a new culture medium that has higher carbon dioxide concentrations and lower oxygen and pH, which encourages more rapid amastigote to promastigote differentiation. Culture is not a reliable method in older lesions, as the organisms become scarce and difficult to isolate.

Serologic tests aim to detect the presence of antibodies against *Leishmania*. They are particularly valuable in visceral and mucocutaneous leishmaniasis.

PCR is a sensitive and powerful method of diagnosis of CL. Recently it was found that important genes involved in the innate immune response to *Leishmania* are downregulated in natural killer (NK) cells from patients with diffuse CL, particularly toll-like receptors (TLRs) and janus kinase/signal transducer and activator of transcription (JAK/STAT) signaling pathways.

Comparison of molecular, microscopic, and culture methods for diagnosis of cutaneous leishmaniasis

Rasti S, Ghorbanzadeh B, Kheirandish F, Mousavi SG, Pirozmand A, Hooshyar H, et al. J Clin Lab Anal 2016; 30: 610–5.

One hundred thirty patients were tested, and 66.9%, 56.2%, 75.4%, 73.8%, and 76.2% were positive for microscopic culture, PCR, nested PCR, and combined PCR and microscopy (proposed method), respectively. Sensitivity, specificity, and positive and negative predictive values of PCR were 99%, 100%, 100%, and 96.9%, respectively, for microscopy; 87.9%, 100%, 100%, and 72.1%, for culture; 72.7%, 100%, 100%, and 53.4%; and 97%, 100%, 100%, and 91.2% for nested PCR. kDNA-PCR was the most sensitive method for

diagnosis of CL.

Molecular detection of *Leishmania* spp. isolated from cutaneous lesions of patients referred to Herat Regional Hospital, Afghanistan

Mosawi SH, Dalimi A. East Mediterr Health J 2016; 21: 878–84.

Light microscopy examination was positive in 58%, whereas PCR was positive in 78% of cases.

Press imprint smear: a rapid, simple, and cheap method for the diagnosis of cutaneous leishmaniasis caused by *Leishmania (Viannia) braziliensis*

Sousa AQ, Pompeu MM, Frutuoso MS, Lima JW, Tinel JM, Pearson RD. Am J Trop Med Hyg 2014; 91: 905–7.

Amastigotes were seen in 92% of 75 patients. The press imprint smear was positive in 85.3%, and histopathology was positive in 44%. It is a rapid and relatively sensitive method for the diagnosis of CL.

Performance of an ELISA and indirect immunofluorescence assay in serologic diagnosis of zoonotic cutaneous leishmaniasis in Iran

Sarkari B, Ashrafmansori M, Hatam G, Habibi P, Abdolahi Khabisi S. Interdiscip Perspect Infect Dis 2014; 505: 134.

Sixty-one sera from parasitologically confirmed CL patients and 50 sera from healthy controls, along with 50 sera from non-CL patients, were studied. Indirect fluorescent antibody (IFA) was used to detect anti-*Leishmania* IgG, ELISA was used to detect anti-*Leishmania* IgM, total IgG, or IgG 1 and IgG4. Sensitivity and specificity of IFA were 91.6% and 81%, respectively. ELISA showed reasonable sensitivity and specificity. Serologic tests can be used for proper diagnosis of CL.

Down-regulation of TLR and JAK/STAT pathway genes is associated with diffuse cutaneous leishmaniasis: a gene expression analysis in NK cells from patients infected with *Leishmania mexicana*

Fernández-Figueroa EA, Imaz-Rosshandler I, Castillo-Fernández JE, Miranda- Ortíz H, Fernández- López JC, Becker I, et al. PLoS Negl Trop Dis March 31, 2016; 10: e0004570.

First-Line Therapies

Pentavalent antimonials

• Meglumine antimoniate	B
• Sodium stibogluconate antimony	B

Clinical features, epidemiology, and efficacy and safety of intralesional antimony treatment of cutaneous leishmaniasis: recent experience in Turkey

Uzun S, Durdu M, Culha G, Allahverdiyev AM, Memisoglu HR. J Parasitol 2004; 90: 853–9.

Intralesional meglumine antimoniate was given as first-line therapy for 890 patients with CL. A weekly dose of 0.2 to 1 mL was given for up to 20 weeks or until complete cure. It was found to have an efficacy of 97.2%, with a low relapse rate (3.9%) and no serious side effects.

Clinical efficacy of intramuscular meglumine antimoniate alone and in combination with intralesional meglumine antimoniate in the treatment of Old World cutaneous leishmaniasis

Munir A, Janjua SA, Hussain I. Acta Dermatovenereol Croat 2008; 16: 60–4.

Sixty patients were studied. A combination of intramuscular meglumine antimoniate 20 mg/kg/day plus intralesional meglumine antimoniate 0.5 mL daily for 21 days was superior to intralesional treatment alone, with 75% complete cure for the former.

Intralesional antimony for single lesions of Bolivian cutaneous leishmaniasis

Soto J, Rojas E, Guzman M, Verduguez A, Nena W, Maldonado M, et al. Clin Infect Dis 2013; 56: 1255–60.

A randomized, open-label trial of 80 patients in Bolivia divided patients into three groups, one receiving either intralesional antimony, cryotherapy, or placebo. At 6 months the cure rate was 70%

for the antimony, 20% for cryotherapy group, and 17% for placebo.

Second-Line Therapies

• Pentamidine isethionate	B
• Rifampin	A
• Azoles	B, A
• Cryotherapy	A, B
• Thermotherapy	B
• Hypertonic sodium chloride	A

Recurrent American cutaneous leishmaniasis

Gangneux JP, Sauzet S, Donnard S, Meyer N, Cornillet A, Pratlong F, et al. *Emerg Infect Dis* 2007; 13: 1436–8.

Twenty-one patients with recurrent CL were enrolled. Intravenous or intramuscular pentamidine isethionate (4 mg/kg) on alternate days cured the lesions within 1 to 3 months.

The role of rifampicin in the management of cutaneous leishmaniasis

Kochar DK, Aseri S, Sharma BV, Bumb RA, Mehta RD, Purohit SK. *Q J Med* 2000; 93: 733–7.

Sixty-four patients were enrolled: 32 received rifampin 600 mg twice daily for 4 weeks, and 32 received placebo. Of the rifampin group, 73.9% had complete healing of their lesions, compared with 4.3% of the placebo group. Rifampin is suitable for multiple lesions and is well tolerated.

Fluconazole for the treatment of cutaneous leishmaniasis caused by *Leishmania major*

Alrajhi AA, Ibrahim EA, De Vol EB, Khairat M, Faris RM, Maguire JH. N Engl J Med 2002; 346: 891–5.

Patients ($n = 106$) received fluconazole 200 mg daily, and 103 received placebo for 6 weeks. Healing was complete in 79% of the fluconazole group and 34% of the placebo group at 3 months, follow-up.

Comparison of oral itraconazole and intramuscular meglumine antimoniate in the treatment of cutaneous leishmaniasis

Saleem K, Rahman A. J Coll Phys Surg Pak 2007; 17: 713–6.

Two hundred patients with wet and dry CL were studied. Itraconazole (100 mg twice daily for 6–8 weeks) was superior to meglumine antimoniate in achieving complete clinical and parasitologic cure (75% compared with 65%), with fewer side effects.

Intralesional sodium stibogluconate alone or its combination with either intramuscular sodium stibogluconate or oral ketoconazole in the treatment of localized cutaneous leishmaniasis: a comparative study

El-Sayed M, Anwar AE. J Eur Acad Dermatol Venereol 2010; 24: 335–40.

Ten patients were treated with intralesional sodium stibogluconate (SSG) alone (group 1). Ten patients were treated with the combination of intralesional SSG + intramuscular SSG (group 2). Ten patients were treated with the combination of intralesional SSG and oral ketoconazole (group 3). Treatment period was 12 weeks. Cure rate was 58.3% in group 1, 93.3% in group 2, and 92.3% in group 3. Combination of oral ketoconazole with intralesional SSG is more effective than intralesional SSG alone.

Efficacy of a weekly cryotherapy regimen to treat *Leishmania major* cutaneous leishmaniasis

Mosleh IM, Geith E, Natsheh L, Schönián G, Abotteen N, Kharabsheh S. J Am Acad Dermatol 2008; 58: 617–24.

Patients ($n = 120$) were treated with cryotherapy once weekly over one to seven sessions; 84% of lesions were cured after one to four sessions. The side effects were minimal.

Evaluation of thermotherapy for the treatment of cutaneous leishmaniasis in Kabul, Afghanistan: a randomized controlled

trial

Case AJ, Safi N, Davis GD, Nadir M, Hamid H, Robert LL Jr. *Mil Med* 2012; 177: 345–51.

Patients ($n = 382$) with CL were randomly assigned to two treatment groups and followed for 6 months. The cure rate for the thermotherapy group was 82.5%, compared with 74% in the glucantime group. A single localized treatment with thermotherapy was more effective than 5 days of intralesional glucantime. Also, thermotherapy was cost effective, with fewer side effects, and better patient compliance than intralesional glucantime.

Thermotherapy effective and safer than miltefosine in the treatment of cutaneous leishmaniasis in Colombia

López L, Cruz C, Godoy G, Robledo SM, Vélez ID. *Rev Inst Med Trop Sao Paulo* 2013; 55: 197–204.

In an open-label trial, one group received oral miltefosine 50 mg daily for 28 days, and the other group received thermotherapy of 50°C on the lesion and perilesional area. There was no statistically significant difference in efficacy between the two groups, but the miltefosine group experienced GI discomfort.

Randomized, double-blind, controlled, comparative study on intralesional 10% and 15% hypertonic saline versus intralesional sodium stibogluconate in *Leishmania donovani* cutaneous leishmaniasis

Ranawaka RR, Weerakoon HS, de Silva SH. *Int J Dermatol* 2015; 54: 555–63.

This was a randomized, double-blind, controlled study of 10% and 15% hypertonic saline injections compared with that of sodium stibogluconate. Four hundred forty-four patients were studied and followed for 18 months. All three groups had cure rates above 90%. The 15% hypertonic saline group showed cutaneous necrosis in 30.6% of lesions, compared with 3.1% of lesions in the 10% hypertonic group. Ten percent hypertonic saline can be considered an alternative to SSG.

Third-Line Therapies

• Miltefosine (hexadecylphosphocholine)	A, B
• Imiquimod 5%	D
• Paromomycin ointment	B
• Photodynamic therapy	B
• Direct current electrotherapy	D
• CO ₂ laser	B
• Intralesional zinc sulfate	A
• Pentoxifylline	B
• Amphotericin	C
• Trichloroacetic acid	B
• Radiofrequency heat therapy	B
• Immunization	A

Miltefosine in the treatment of cutaneous leishmaniasis caused by *Leishmania braziliensis* in Brazil: a randomized and controlled trial

Machado PR, Ampuero J, Guimarães LH, Villasboas L, Rocha AT, Schriefer A, et al. PLoS Negl Trop Dis 2010; 21: e912.

Ninety patients were enrolled; 60 received miltefosine orally and 30 received pentavalent antimony. Six months later, the cure rate was 53.3% in the pentavalent antimony group and 75% in the miltefosine group. Apoptosis-like death of *Leishmania donovani* may be a possible explanation of the mode of action of miltefosine.

Role of imiquimod and parenteral meglumine antimoniate in the initial treatment of cutaneous leishmaniasis

Arevalo I, Tulliano G, Quispe A, Spaeth G, Matlashewski G, Llanos-Cuentas A, et al. Clin Infect Dis 2007; 44: 1549–54.

Combination treatment with imiquimod and meglumine antimoniate gave superior results, with rapid healing and better cosmetic outcome. Imiquimod kills the intracellular *Leishmania amastigotes* in vitro by activating macrophages to release nitric oxide.

Topical paromomycin with or without gentamicin for cutaneous leishmaniasis

Ben Salah A, Ben Messaoud N, Guedri E, Zaatour A, Ben Alaya N, Bettaieb J, et al. N Engl J Med 2013; 368: 524–32.

A randomized, controlled study of 375 patients using topical paromomycin with and without gentamicin for ulcerative CL. Three groups received 15% topical paromomycin and 0.5% gentamicin, paromomycin alone, or control. Treatment continued for 20 days; cure rates were 81%, 82%, and 58% for the paromomycin–gentamicin, paromomycin, and control groups, respectively.

Comparison between the efficacy of photodynamic therapy and topical paromomycin in the treatment of Old World cutaneous leishmaniasis: a placebo-controlled, randomized clinical trial

Asilian A, Davami M. Clin Exp Dermatol 2006; 31: 634–7.

This study compared the parasitologic and clinical efficacy of photodynamic therapy (PDT) and topical paromomycin in 60 patients. Topical PDT was given weekly for 4 weeks. Complete improvement was seen in 93.5% of patients treated with topical PDT versus 41.2% in the topical paromomycin group.

The parasitocidal effect of electricity on *Leishmania major*, both in vitro and in vivo

Hejazi H, Eslami G, Dalimi A. Ann Trop Med Parasitol 2004; 98: 37–42.

Exposure to direct current of 3, 6, 9, and 12 V (at 0.2–10.7 mA) killed all promastigotes (in culture) within 10 to 15 minutes. Three weeks of electrotherapy at 3 V for 10 minutes twice weekly appeared to cure all the lesions in mice.

Efficacy of CO₂ laser for treatment of anthroponotic cutaneous leishmaniasis, compared with combination of cryotherapy and intralesional meglumine antimoniate

Shamsi Meymandi S, Zandi S, Aghaie H, Heshmatkhah A. J Eur Acad Dermatol Venereol 2011; 25: 587–91.

Single treatment session of CO₂ laser was more effective in treating dry-type CL than combined cryotherapy and intralesional glucantime with a shorter healing time (6 weeks vs. 12 weeks).

Comparison of intralesionally injected zinc sulfate with meglumine antimoniate in the treatment of acute cutaneous leishmaniasis

Iraji F, Vali A, Asilian A, Shahtalebi MA, Momeni AZ. *Dermatology* 2004; 209: 46–9.

A total of 104 patients with acute cutaneous leishmaniasis (ACL) were studied. The duration of treatment was 6 weeks. Thirty-five patients received meglumine antimoniate, and 31 received intralesional zinc sulfate. Cure rates were 60% for meglumine antimoniate and 83.8% for zinc sulfate. Intralesional injection of 2% zinc sulfate is a good alternative for the treatment of ACL.

Clinical and immunologic outcome in cutaneous leishmaniasis patients treated with pentoxifylline

Brito G, Dourado M, Polari L, Celestino D, Carvalho LP, Queiroz A, et al. *Am J Trop Med Hyg* 2014; 90: 617–20.

Thirty-six patients with CL were studied. One group received intralesional antimony along with pentoxifylline, and the other received antimony with placebo. The pentoxifylline group showed a decrease in tumor necrosis factor-alpha (TNF- α) and interferon-gamma levels compared with the placebo group. Cure rate was higher in the pentoxifylline group, but not statistically significant. Pentoxifylline has an antiinflammatory effect.

Liposomal amphotericin B treatment of cutaneous leishmaniasis due to *Leishmania tropica*

Solomon M, Pavlotsky F, Leshem E, Ephros M, Trau H, Schwartz E. *J Eur Acad Dermatol Venereol* 2011; 25: 973–7.

Thirteen patients received liposomal amphotericin B (5 consecutive days of 3 mg/kg, followed by a sixth dose on day 10); 85% had facial lesions. Eleven of 13 patients (84%) achieved complete clinical cure within 2 months. There were no reported relapses after 11 months, and the side effects were mild.

The efficacy of 5% trichloroacetic acid cream in the treatment of cutaneous leishmaniasis lesions

Ali NM, Fariba J, Elaheh H, Ali N. J Dermatolog Treat 2012; 23: 136–9.

Sixteen patients with CL were treated with 5% trichloroacetic acid cream twice daily for 8 weeks. Mean area of the lesions was $38.81 \pm 81.9 \text{ mm}^2$. After 6 months, it was $3.6 \pm 9.1 \text{ mm}^2$. All patients were cured by week 8. No side effects.

Long-term efficacy of single-dose radiofrequency-induced heat therapy vs. intralesional antimonials for cutaneous leishmaniasis in India: RFHT for cutaneous leishmaniasis

Bumb RA, Prasad N, Khandelwal K, Aara N, Mehta RD, Ghiya BC, et al. Br J Dermatol 2013; 168: 1114–9.

One hundred patients with CL were studied. Fifty patients received one treatment of radiofrequency-induced heat therapy (RFHT); the other 50 received intralesional SSG injections. Follow-up was for 18 months. After 6 months, the cure rate was 98% in the RFHT group and 95% in the SSG group. No relapse in any patient.

Cluster randomised trial to evaluate the effectiveness of a vaccine against cutaneous leishmaniasis in the Caratinga microregion, south-east Brazil

Mayrink W, Mendonca-Mendes A, de Paula JC, Siqueira LM, Marrocos Sde R, Dias ES, et al. Trans R Soc Trop Med Hyg 2013; 107: 212–9.

A randomized trial of 8734 patients in a Brazilian area with a high frequency of CL were given a killed vaccine from 2002 to 2011. They showed a significantly lower number of individuals infected with CL in the vaccine group compared with the placebo group.

Lentigo maligna

Aaron S. Farberg, and Darrell S. Rigel

Lentigo maligna (LM) is a subtype of preinvasive intraepidermal melanoma that classically presents as widespread pigmented patches of atypical melanocytes in the background of long-standing sun damage. The lifetime risk of LM progressing to invasive lentigo malignant melanoma (LMM) varies from 2.2% to 4.7%, depending on patient age at diagnosis. LMM represents 4% to 15% of all melanomas, and its incidence is increasing at a greater rate than any other melanoma subtype. The widespread atypical melanocytes often originate on the head or neck and spread slowly. LM has traditionally been challenging to diagnose because it is difficult to distinguish nonmalignant atypical melanocytic hyperplasia from melanoma in

situ (MIS) in chronically sun-damaged skin. Treatment of LM remains complex, with recurrence rates that remain high (2%–50%) due to subclinical extension and difficulty of determining tumor margins.

Management Strategy

Successful management of LM depends on early diagnosis and definitive removal. The differential diagnosis includes solar lentigo, macular seborrheic keratosis, pigmented actinic keratosis, pigmented squamous cell carcinoma in situ, and pigmented superficial basal cell carcinoma. Confirmatory biopsy is necessary before definitive treatment. The use of a Wood lamp may help to determine the perimeter of the lesion. Dermoscopy may also be helpful. Excisional biopsy of the entire lesion is ideal in order to ascertain its maximum depth. However, the lesion tends to be large (>1 cm) due to its propensity for extensive radial growth before vertical growth into the dermis. Therefore biopsy of part of the lesion is often performed. Treatment is primarily surgical, although eradication by other methods may be considered. Patients with a history of LM should have periodic full-body skin examinations by a dermatologist to allow for early detection of recurrence, progression, or a second primary skin cancer. Patients with LM also require a consultation about sun protection behaviors.

Specific Investigation

- Skin biopsy and patient evaluation

Diagnosis and treatment of early melanoma

NIH Consensus Statement. 1992; 10: 1–26.

Biopsy of sufficient depth is critical for diagnosis and management of pigmented lesions. Punch, saucerization, excision, or incisional biopsy may be acceptable. On microscopic examination LM is characterized by increased numbers of atypical melanocytes at the epidermal-dermal junction, which may be solitary or arranged in nests but do not invade the dermis. Evaluation should include a personal and family history, complete skin examination, and palpation of regional lymph nodes. Blood tests or imaging studies are not indicated.

First-Line Therapies

• Excision	A
• Mohs micrographic surgery	D
• Modified Mohs surgery	D
• Staged excision	D

Diagnosis and treatment of early melanoma

NIH Consensus Statement. 1992; 10: 1–26.

Current recommendations are based on the National Institutes of Health (NIH) consensus for MIS, which suggests excision of the lesion or biopsy site with a margin of 0.5 cm of clinically normal skin and layer of subcutaneous tissue. In general, margins of 0.5 to 1.0 cm are suggested for LM where feasible. Difficulties may arise in determination of clinical margins due to diffuse background sun damage. A Wood lamp may be useful in defining subclinical extension. Reflectance confocal microscopy (RCM) may also improve diagnostic accuracy of LM by identifying optimal biopsy sites. RCM may assist in presurgical mapping, intraoperative margin assessment, assessing response to nonsurgical therapies, and monitoring for recurrence. Accurate determination of margins is key because LM is likely to recur after inadequate excision.

Usefulness of the staged excision for lentigo maligna and lentigo maligna melanoma: the “square” procedure

Johnson TM, Headington JT, Baker SR, Lowe L. J Am Acad Dermatol 1997; 37: 758–64.

With this technique, a margin of 0.5 to 1.0 cm is outlined with angled corners to facilitate processing. A peripheral strip of tissue 2 to 4 cm wide is excised and processed for evaluation of permanent sections. Residual tumor is subsequently excised in a directed fashion

based on mapping. There were no recurrences in 35 patients at 2 years.

Mohs micrographic surgery is accurate 95.1% of the time for melanoma in situ: a prospective study of 167 cases

Bene NI, Healy C, Coldiron BM. Dermatol Surg 2008; 34: 660–4.

Patients ($n = 116$) with MIS in sun-exposed skin of LMM type were treated by Mohs micrographic surgery (MMS) with subsequent evaluation of the final margin with paraffin-embedded sections that were cut en face over a period of 12 years (mean follow-up, 50 months; median 48 months; 594.5 patient-years). The clearance rate by MMS technique using frozen sections was 94.1% for the MIS LM type. The cure rate was 99.0% for the MIS LM type.

MMS is a viable option for treatment of MIS that may increase cure rate and reduce the size of the defect, especially in cosmetically and functionally sensitive areas.

Conventional surgery compared with slow Mohs micrographic surgery in the treatment of lentigo maligna: a retrospective study of 62 cases

Hilari H, Llorca D, Traves V, Villanueva A, Serra-Guillén C, Requena C, et al. Actas Dermosifiliogr 2012; 103: 614–23.

A review of the clinical records of patients with LM of the head treated definitively with conventional surgical excision or slow MMS at the dermatology department of Instituto Valenciano de Oncología between January 1993 and April 2011 was reported. Surgical margins larger than 0.5 cm were required in 69.2% of recurrent LM and 26.5% of primary LM. Factors associated with the need for wider margins were prior treatment that might have interfered with the clinical delineation of the border, lesions in the center of the face, and skin phototypes III to V. Surgical margins of 0.5 cm are inadequate for the treatment of a considerable number of LM lesions located on the head, particularly if these are recurrent. Slow MMS using paraffin-embedded sections appears to be the treatment of choice in such cases, particularly for recurrent lesions or lesions with poorly defined borders or possible subclinical extension.

A potential disadvantage of relying on “slow Mohs” is the amount of time added to each procedure. In addition, the technique depends on off-site tissue processing and interpretation, thereby magnifying the possibility of error.

Recurrence rate of lentigo maligna after micrographically controlled staged surgical excision

De Vries K, Greveling K, Prens LM, Munte K, Koljenovic, van Doorn MBA, et al. *Br J Dermatol* 2016; 174: 588–93.

This is a retrospective review of records of all patients at an academic medical center in the Netherlands diagnosed with LM treated with staged surgical excision between 2002 and 2011. Recurrences were identified through the nationwide network registry with a 5-year mean follow-up. Of 100 patients identified, 4 had a recurrence. Staged surgical excision may provide a high clearance and low recurrence rate.

Five-year outcomes of wide excision and Mohs micrographic surgery for primary lentigo maligna in an academic practice cohort

Hou JL, Reed KB, Knudson RM, Mirzoyev SA, Lohse CM, Frohm ML, et al. *Dermatol Surg* 2015; 41: 211–8.

This retrospective study evaluated the outcomes of MMS versus wide excision with 5-mm margins in a cohort from a single academic practice. Four hundred twenty-three LM lesions were treated with either wide excision (269) or Mohs (154). Recurrence rates were 1.9% for the Mohs-treated group and 5.9% for the wide excision group. The study concluded Mohs surgery may offer increased cure rates and avoid the need for repeat surgery and thus may be the preferred treatment for LM.

Geometric staged excision for the treatment of lentigo maligna and lentigo maligna melanoma: a long-term experience with literature review

Abdelmalek M, Loosemore MP, Hurt MA, Hruza G. *Arch Dermatol* 2012; 148: 599–604.

All patients with a diagnosis of LM and LMM were treated by staged excision from 1999 to 2007. The rate of recurrence after geometric staged excision was 1.7% (4 of 239), with a mean of 32.3 months of follow-up. The mean margin to clearance after excision was 6.6 mm for LM and 8.2 mm for LMM. A total of 11.7% of LMM was initially diagnosed as LM on biopsy, with the invasive component discovered during the excision.

Staged excision for lentigo maligna and lentigo maligna

melanoma: a retrospective analysis of 117 cases

Hazan C, Dusza SW, Delgado R, Busam KJ, Halpern AC, Nehal KS. *J Am Acad Dermatol* 2008; 58: 142–8.

The authors conducted a retrospective study of 117 LM and LMM cases treated with a staged margin-controlled excision technique with rush paraffin-embedded sections. The mean total surgical margin required for excision of LM was 0.71 cm and was 1.03 cm for LMM. The study concluded that the standard excision margins for LM and LMM are often inadequate, and occult invasive melanoma occurs in LM.

Intraoperative real-time reflectance confocal microscopy for guiding surgical margins of lentigo maligna melanoma

Hibler BP, Cordova M, Wong RJ, Rossi AM. *Dermatol Surg* 2015; 41: 980–3.

This case study demonstrates the utility of RCM in augmenting the management of LM. It may be used to guide surgical management to verify surgical margins to decrease patient morbidity. Initial cost and the associated learning curve are limitations to widespread use of the technology.

Videodermatoscopy-assisted Mohs micrographic surgery vs. other treatments for lentigo maligna in 54 patients with a long-term follow-up

Dika E, Fanti PA, Christman H, Piraccini BM, Misciali C, Vaccari S, et al. *J Eur Acad Dermatol Venereol* 2016; 30: 1440–1.

This retrospective single-center study included patients with LM on the head and neck referred for surgical excision with at least 5 years of follow-up. Videodermatoscopy-assisted MMS was used to evaluate all margins, and additional excision was performed where positive for frozen sections. Patients were divided into three groups: standard excision, MMS, and videodermatoscopy-assisted MMS. Videodermatoscopy-assisted MMS reduced the number of steps and overall timing of the surgical procedure. Recurrence was 24% for standard excision, 5% of MMS, and 0% in the videodermatoscopy-assisted MMS group.

AAD/ACMS/ASDSA/ASMS 2012 appropriate use criteria for Mohs micrographic surgery: a report of the American Academy of Dermatology, American College of Mohs Surgery, American

Society for Dermatologic Surgery Association, and the American Society for Mohs Surgery

Connolly SM, Baker DR, Coldiron BM, Fazio MJ, Storrs PA, Vidimos AT, et al. J Am Acad Dermatol 2012; 67: 531–50.

Of all the clinical scenarios for LM as determined by this consortium, five were deemed appropriate for Mohs surgery, one uncertain, and zero inappropriate with consensus reached for all scenarios. MMS was deemed appropriate for primary LM in areas H and M (face, genitalia, hands, feet, nails, pretibial surface, ankles, areolae) for healthy and immunocompromised patients. Locally recurrent LM was rated appropriate for MMS in all body locations for both healthy and immunocompromised patients. The use of MMS for primary LM in healthy or immunocompromised patients was determined to be uncertain when located on area L (trunk and extremities excluding pretibial, hands, feet, nails, ankles).

Second-Line Therapies

• Radiation therapy	D
• Cryotherapy	D

Radiotherapy for lentigo maligna: a literature review and recommendations for treatment

Fogarty GB, Scolyer RA, Lin E, Haydu L, Guitera P, Thompson J. Br J Dermatol 2013; 170: 52–8.

Nine studies described 537 patients with LM treated with definitive primary radiotherapy. There was a 5% recurrence rate of 349 assessable patients. Salvage was successful in most recurrent cases. Progression to LMM occurred in 5 patients. Marginal and in-field recurrence rates were 4% and 5%, respectively. Median study follow-up was 3 years.

Grenz ray treatment of lentigo maligna and early lentigo maligna

melanoma

Hedblad MA, Mallbris L. J Am Acad Dermatol 2012; 67: 60–8.

Patients ($n = 593$) were treated with Grenz rays (GR) (primary therapy, $n = 350$; partial excision followed by GR, $n = 71$; radical excision followed by GR as recurrence-prophylactic treatment, $n = 172$) at the Department of Dermatology, Karolinska University Hospital, Stockholm, Sweden, between 1990 and 2009. The treatment was given twice a week over 3 consecutive weeks in total doses of 100 to 160 Gy. Dosage depended on the stage of LM and the depth of periadnexal atypical melanocytic extension in histologically examined materials before treatment. Four hundred twenty-five patients have been followed up for at least 2 years and, of these, 241 for 5 years. Overall, 520 of 593 patients (88%) showed complete clearance after one fractionated treatment. Residual lesions were seen in 15 patients, and 58 relapsed, 53 of whom (72%) within 2 years.

One of the advantages of this soft x-ray or Miescher technique is exclusion of underlying bone and minimization of risk of bony necrosis. The potential disadvantage is inadequate depth of penetration.

Cryosurgery for lentigo maligna

Kuflik E, Gage A. J Am Acad Dermatol 1994; 31: 75–8.

Thirty white patients were treated with cryosurgery. The lesions ranged from 1.3 to 4.5 cm in diameter. Treatment consisted of freezing with liquid nitrogen delivered by open spray. Lesions recurred in two patients, yielding a recurrence rate of 6.6% during the average follow-up period of 3 years. The two recurrent lesions were successfully retreated with cryosurgery. Eleven patients observed for more than 5 years showed no recurrence.

Third-Line Therapies

• Q-switched ruby laser	E
• Q-switched neodymium-doped yttrium aluminium garnet laser	D
• CO ₂ laser	D
• Interferon- α	D, E
• Imiquimod	D
• Tazarotene	E
• Photodynamic therapy	D
• Combination therapy	D

Q-switched neodymium:yttrium-aluminum-garnet laser treatment of lentigo maligna

Orten SS, Waner M, Dinehart SM, Bardales RH, Flock ST. Otolaryngol Head Neck Surg 1999; 120: 296–302.

Eight patients with LM were treated with the neodymium-doped yttrium aluminium garnet laser. Three patients were treated with both 532 and 1064 nm. Two of these had complete eradication without recurrence at 3.5 years. The other showed a partial response but died of unrelated causes before completion of therapy.

The Nd:YAG laser emits energy at 532 nm and 1064 nm, which may be especially suited to LM. Melanin has greater absorption at 532 nm, whereas the longer wavelength, 1064 nm, may provide deeper penetration.

Carbon dioxide laser treatment for lentigo maligna: a retrospective review comparing 3 different treatment modalities

Lee H, Sowerby LJ, Temple CL, Yu E, Moore CC. Arch Facial Plast Surg 2011; 13: 398–403.

Seventy-three patients aged 39 to 93 years (mean age, 64.8 years) were included in the study. Twenty-seven patients were treated with surgical excision, 31 patients with radiation therapy, and 15 patients with CO₂ laser ablation. The median follow-up times were 16.6 months for surgical excision, 46.3 months for radiation therapy, and 77.8 months for CO₂ laser ablation ($p < 0.001$). Recurrence rates by treatment modality were 4.2% (1 of 27) for surgical excision, 29.0% (9 of 31) for radiation therapy, and 6.7% (1 of 15) for CO₂ laser ablation. A trend toward lower recurrence rates with surgical excision and CO₂

laser ablation was identified, but the results were not statistically significant.

CO₂ laser ablation may have a role as an alternative treatment for lentigo maligna among patients in whom standard treatments, such as surgical excision and radiation therapy, are declined or carry significant morbidity.

Intralesional interferon treatment of lentigo maligna

Cornejo P, Vanaclocha F, Polimon I, Del Rio R. Arch Dermatol 2000; 136: 428–30.

Interferon- α is a biological response modifier indicated for adjunctive treatment of high-risk melanoma. The mechanism involves both immunomodulation and direct antiproliferative effects. Successful treatment of 11 LM lesions in 10 patients at doses of 3×10^6 to 6×10^6 IU administered three times weekly is reported, with clearance in all patients after between 12 and 29 doses.

Topical 5% imiquimod in the treatment of lentigo maligna

Wong JG, Toole JW, Demers AA, Musto G, Wiseman MC. J Cutan Med Surg 2012; 16: 245–9.

Twenty-seven patients were reviewed. There were 20 responders (74.1%) and 7 failures. The mean tumor size (area of an ellipse) was 6.69 cm², and the mean treatment duration was 17.7 weeks. Neither the size of the tumor ($p = 0.86$) nor treatment duration ($p = 0.18$) was related to resolution of the lesion. Imiquimod is an effective treatment for LM that provides patients with a cosmetically favorable outcome when standard surgery is not an option.

A quantitative systematic review of the efficacy of imiquimod monotherapy for lentigo maligna and an analysis of factors that affect tumor clearance

Mora AN, Karia PS, Nguyen BM. J Am Acad Dermatol 2015; 73: 205–12.

This systematic review based on 347 tumors from 45 studies revealed histologic and clinical clearance rates to be 76.2% and 78.3%, respectively. The incidence of clinical recurrence was 2.3% with a mean follow-up of 34 months. Treatment with more than 60 total applications or more than 5 applications per week was associated with a higher likelihood of clearance.

Imiquimod 5% cream as primary or adjuvant therapy for

melanoma in situ, lentigo maligna type

Swetter SM, Chen FW, Kim DD, Egbert BM. *J Am Acad Dermatol* 2015; 72: 1047–53.

Fifty-eight cases analyzed for local recurrence after topical imiquimod 5% treatment for either primary therapy or adjuvant after narrow-margin excision. In this study 86.2% demonstrated clinical clearance at mean follow-up of 42.1 months; 72.7% primary and 94.4% adjuvant. Imiquimod cream appears to be a viable option for primary or adjuvant treatment of LM in patients who are poor surgical candidates.

Treatment of lentigo maligna with imiquimod cream: a long-term follow-up study of 10 patients

Van Meurs T, Van Doorn R, Kirtschig G. *Dermatol Surg* 2010; 36: 853–8.

Ten patients with LM were treated with imiquimod 5% cream between 2004 and 2007 with a median follow-up of 31 months (range 11–56 months). Histologic clearance was assessed in all patients using posttreatment biopsies. Complete clinical clearance was achieved in 9 of 10 patients after treatment with imiquimod. During follow-up, three clinical and histologic recurrences were observed at 9, 10, and 27 months after treatment cessation. In a fourth patient, histologic recurrence without clinical signs was demonstrated 17 months after treatment. Five of 10 patients were in sustained clinical remission.

Treatment of lentigo maligna with tazarotene 0.1% gel

Chimenti S, Carrozzo AM, Citarella L, De Felice C, Peris K. *J Am Acad Dermatol* 2004; 50: 101–3.

In this series, two elderly patients with facial LM were treated with daily application of tazarotene gel 0.1% for 6 to 8 months. No recurrence in either patient was observed after follow-up periods of 18 and 30 months, respectively. These results should be interpreted with caution, considering the relatively short follow-up.

The use of photodynamic therapy in the treatment of lentigo maligna

Karam A, Simon M, Lemasson G, Misery L. *Pigment Cell Melanoma Res* 2013; 26: 275–7.

This study included 15 cases from a retrospective single-center review of patients with LM on the face. Patients underwent

aminolevulinate treatment before red light therapy (40–90 J/cm²) from three to nine sessions at 3-week intervals. Initial clinical evaluation occurred after three sessions, and three immediate failures were observed. Clinical and histologic healing was observed in the other patients with a 10- to 29-month follow-up.

A randomized trial of the off-label use of imiquimod 5% cream with vs. without tazarotene 0.1% gel for the treatment of lentigo maligna, followed by conservative staged excisions

Hyde MA, Hadley ML, Tristani-Firouzi P, Goldgar D, Bowen GM. Arch Dermatol 2012; 148: 592–6.

Ninety patients with 91 LMs were randomized into two groups. One group received imiquimod 5% cream 5 days a week for 3 months, whereas the other group also received tazarotene 0.1% gel 2 days a week for 3 months. After topical therapy, all patients underwent staged excisions and frozen section analysis with melan-A immunostaining to confirm negative margins. Forty-six patients with 47 LMs were randomized to receive monotherapy: 42 of 47 LMs reached the intended treatment duration, with 27 complete responses (64%). Forty-four patients with 44 LMs were randomized to receive combined therapy. Thirty-seven of 44 LMs reached the intended treatment duration, with 29 complete responses (78%). This difference did not reach statistical significance ($p = 0.17$). There have been no recurrences to date, with a mean follow-up period of 42 months.

Pretreating LM with imiquimod 5% cream may decrease surgical defect sizes; however, total reliance on topical imiquimod as an alternative to surgery may put the patient at increased risk of a local recurrence.

A two-staged treatment of lentigo maligna using ablative laser therapy followed by imiquimod: excellent cosmesis, but frequent recurrences on the nose

Greveling K, de Vries K, van Doorn MB, Prens EP. Br J Dermatol 2016; 174: 1134–6.

Retrospective study of ablative laser therapy followed by 6 weeks of topical imiquimod 5% cream (5 days/week). Thirty-five patients were treated with median follow-up of 42 and 14 months for different cohorts. A strong inflammatory response was found in 100% of the subjects in contrast to imiquimod monotherapy where there were nonresponders. After 2 and 3 years of follow-up, cumulative incidence of recurrence was 23.5%, with five of six being on the nose.

Patient self-rated cosmetic outcome was 8.5/10.

Leprosy (including reactions)

Anne E. Burdick, and Ivan D. Camacho

Leprosy, or Hansen disease, is an infection caused by *Mycobacterium leprae* (*M. leprae*), affecting the skin, respiratory

mucosa, peripheral nerves, and other organs. The cardinal features are anesthetic skin lesions, enlarged peripheral nerves, and peripheral neuropathy with acid-fast bacilli (AFB) in tissue biopsies or skin slit smears. A patient's cell-mediated immunity against *M. leprae* determines his or her presentation of leprosy in the Ridley–Jopling spectrum: tuberculoid (TT), borderline tuberculoid (BT), midborderline (BB), borderline lepromatous (BL), and lepromatous (LL). A patient with TT leprosy has high cell-mediated immunity to *M. leprae* and few well-demarcated lesions located on cooler parts of the body. A patient with LL leprosy has low cell-mediated immunity to *M. leprae* and numerous disseminated infiltrated erythematous papules, plaques, and nodules, often presenting with peripheral neuropathy. BB leprosy patients have multiple annular “dimorphous” plaques (see figure). On biopsy, TT lesions reveal rare and sometimes absence of AFB; polymerase chain reaction (PCR) may be positive. LL lesions have innumerable AFB. Indeterminate (I) leprosy presents as a single or a few hypopigmented patches that tend to resolve spontaneously but may progress to leprosy anywhere on the spectrum. Pure neural leprosy is limited to peripheral nerve involvement without skin lesions.

Leprosy reactions occur in 25% to 50% of patients before, during, or after treatment. BT, BB, and BL patients may develop a delayed hypersensitivity reaction, a type 1 “reversal” reaction, with the reappearance of red edematous lesions and an acute peripheral neuritis. Patients on etanercept, infliximab, and adalimumab may manifest leprosy and a type 1 reversal reaction if they have concomitant subclinical leprosy. HIV patients may develop BT lesions and a type 1 reversal reaction as an immune reconstitution inflammatory syndrome within 6 months of starting highly active antiretroviral therapy if they also have a subclinical leprosy infection.

Erythema nodosum leprosum, a type 2 reaction, is an immune complex reaction that develops in BL and LL cases. In a type 2 reaction, crops of new red, indurated, tender papules, plaques, or nodules develop, usually with fever and occasionally with iritis or orchitis. Lucio phenomenon, a rare vasculitic reaction, presents as tender purpuric and necrotic lesions in BL and LL cases.

Management Strategy

Leprosy treatment consists of multidrug therapy with *rifampicin* and

dapsone, with or without *clofazimine*. For treatment purposes, the World Health Organization (WHO) classifies I, TT, and BT cases as paucibacillary and recommends monthly rifampicin 600 mg and daily dapsone 100 mg for 6 months. WHO classifies BB, BL, and LL cases as multibacillary and recommends monthly rifampicin 600 mg, daily dapsone 100 mg, and clofazimine 300 mg monthly and 50 mg daily for 12 months.

The U.S. National Hansen's Disease Program guidelines are different. For paucibacillary cases, daily rifampicin 600 mg and daily dapsone 100 mg are recommended for 12 months. For multibacillary cases, daily rifampicin 600 mg, daily dapsone 100 mg, and daily clofazimine 50 mg are recommended for 24 months. In the United States, clofazimine is available only through the National Hansen's Disease Program as an investigational drug.

If clofazimine is not available or declined due to skin hyperpigmentation, or if a patient cannot take rifampicin or dapsone, alternative antibiotics are *minocycline* 100 mg, *ofloxacin* 400 mg, *Levaquin* 500 mg, *clarithromycin* 500 mg, or *moxifloxacin* 400 mg. Rifampicin is often prescribed monthly for patients on prednisone, warfarin, oral contraceptives, and other drugs with metabolism affected by rifampicin. If multidrug therapy is interrupted for any reason, it should be resumed when possible for the remaining months required to complete the recommended duration of multidrug therapy.

Multidrug therapy should be continued during reactions. Mild type 1 reversal reactions and type 2 reactions are treated with *nonsteroidal antiinflammatory drugs*. For a severe type 1 reversal reaction with acute neuritis, particularly involving the face, aggressive therapy with systemic steroids is started to prevent potentially irreversible nerve damage. *Prednisone* 0.5 to 1 mg/kg daily should be started and tapered slowly, 5 to 10 mg every 2 to 4 weeks, for 3 to 6 months or longer depending on the patient's response. Because high doses of steroids are often required to control a type 1 reversal reaction, the addition of a steroid-sparing drug should be considered. *Methotrexate* and *ciclosporin* are effective for a type 1 reversal reaction, permitting a decreased dose or discontinuation of prednisone.

A severe type 2 reaction also responds to prednisone 0.5 to 1 mg/kg daily and often requires a slower taper of 6 months or longer. *Thalidomide*, a known teratogen, is the drug of choice for men and for women who are postmenopausal, surgically sterile, or are using

appropriate contraceptives. The initial thalidomide dose ranges from 100 to 300 mg nightly depending on the type 2 reaction severity. The dose is decreased slowly over several months to a maintenance dose of 50 to 100 mg nightly to prevent recurrences. Other drugs for type 2 reaction include *methotrexate*, *azathioprine*, *infliximab*, and *etanercept*. Lucio phenomenon is treated with prednisone, *low-dose aspirin*, and wound care.

After completion of multidrug therapy, the National Hansen's Disease Program advises paucibacillary patients to be screened annually for 5 years and multibacillary patients for 8 years. Household contacts who lived with a leprosy patient during the 3 years before multidrug therapy was started should have one screening examination according to WHO. The National Hansen's Disease Program also recommends one screening for paucibacillary leprosy contacts and advises an annual screening for 5 years for multibacillary leprosy contacts.

For leprosy neuropathy and neuritis, *gabapentin*, *pregabalin*, or *amitriptyline* alleviates the pain.

Specific Investigations

- Skin biopsy from periphery of lesion for diagnosis and annually
- PCR for diagnosis if a paucibacillary lesion biopsy does not show
- Slit skin smears
- Neurosensory testing
- Chemistry panel, complete blood count
- Glucose-6-phosphate dehydrogenase level before dapsone
- Urinalysis (type 2 reaction)
- Purified protein derivative (PPD) or QuantiFERON Gold before immunosuppression
- Hepatitis screening
- HLA-B13 in Asians with increased risk of dapsone hypersensitivity reaction

First-Line Therapies

• Rifampicin and dapsone (paucibacillary and multibacillary)	B
• Clofazimine (in addition to rifampicin and dapsone, for multibacillary and, in high doses, for type 2 reaction)	B
• Nonsteroidal antiinflammatory drugs (type 1 reversal reaction and type 2 reaction)	D
• Prednisone (type 1 reversal reaction and type 2 reaction)	D
• Thalidomide (type 2 reaction)	D

Second-Line Therapies

• Minocycline, Levaquin, ofloxacin, clarithromycin, moxifloxacin,	B
• Methotrexate (type 1 reversal reaction and type 2 reaction)	B
• Ciclosporin (type 1 reversal reaction)	D
• Azathioprine (type 2 reaction)	D
• Infliximab (type 2 reaction)	D
• Etanercept (type 2 reaction)	D
• Gabapentin or pregabalin (neuropathy and neuritis)	D
• Amitriptyline (neuropathy and neuritis)	D

Response to cyclosporine treatment in Ethiopian and Nepali patients with severe leprosy type 1 reactions

Marlowe SN, Leekassa R, Bizuneh E, Knuutilla J, Ale P, Bhattarai B, et al. Trans R Soc Trop Med Hyg 2007; 101: 1004–12.

Forty-one patients with type 1 reversal reaction treated with ciclosporin 5 to 7.5 mg/kg/day for 12 weeks had 67% to 100% improvement after 24 weeks. Neuritis recurred when discontinued.

Cyclosporin A treatment of leprosy patients with chronic neuritis is associated with pain control and reduction in antibodies against nerve growth factor

Sena CB, Salgado CG, Tavares CM, Da Cruz CA, Xavier MG, Do Nascimento JL. Lepr Rev 2006; 77: 121–9.

Twenty patients with neuritis unresponsive to 40 mg/day prednisone had improved sensation, strength, and pain after ciclosporin 5 mg/kg/day with a 12-month taper.

Using methotrexate to treat patients with ENL unresponsive to

steroids and clofazimine: a report on 9 patients

Hossain D. *Lepr Rev* 2013; 82: 105–12.

Nine patients with type 2 erythema nodosum leprosum resistant to prednisone and clofazimine responded well to prednisolone (30–40 mg/day for 3–6 months, then dose was halved and tapered slowly over 2.5–3 years) with methotrexate (7.5 mg weekly for 24–36 months). Patients remained relapse free for 2.5 years.

Methotrexate treatment for type 1 (reversal) leprosy reactions

Biosca G, Casallo S, López-Vélez R. *Clin Infect Dis* 2007; 45: e7–9.

A BL patient with type 1 reversal reaction and poor tolerance to corticosteroids responded to methotrexate 7.5 mg weekly. Prednisone was stopped in 2 months, and lesions resolved in 6 months.

Methotrexate in resistant ENL

Kar BR, Babu R. *Int J Lepr Other Mycobact Dis* 2004; 72: 480–2.

A patient with a type 2 reaction unresponsive to prednisolone 50 mg daily improved with methotrexate 15 mg weekly for 2 weeks. Prednisolone was tapered to 20 mg daily with continued improvement on methotrexate 7.5 mg weekly.

Azathioprine as a steroid sparing agent in leprosy type 2 reactions: report of nine cases

Duraes SM, Salles SA, Leite VR, Gazzeta MO. *Lepr Rev* 2011; 82: 304–9.

Review of nine reports of type 2 reaction cases refractory to prednisone and clofazimine responding to azathioprine 2 to 3 mg/kg/day. The prednisone dose was decreased in 4 weeks and halved after 12 weeks with fewer type 2 reactions.

Clinical outcomes in a randomized controlled study comparing azathioprine and prednisolone versus prednisolone alone in the treatment of severe leprosy type 1 reactions in Nepal

Marlowe SN, Hawksworth RA, Butlin CR, Nicholls PG, Lockwood DN. *Trans R Soc Trop Med Hyg* 2004; 98: 602–9.

Forty patients with type 2 reversal reaction randomized to prednisolone 40 mg daily vs. prednisolone 40 mg daily with azathioprine 3 mg/kg daily for 12 weeks had no difference in outcome.

Severe refractory erythema nodosum leprosum successfully treated with the tumor necrosis factor inhibitor etanercept

Ramien ML, Wong A, Keystone JS. Clin Infect Dis 2011; 52: e133–5.

An LL patient who had type 2 reactions for 6 years despite daily thalidomide 100 mg and multiple courses of 40 to 60 mg/day of prednisone improved on etanercept 50 mg subcutaneously weekly for 6 weeks. Prednisone and thalidomide were stopped in 6 months.

Treatment of recurrent erythema nodosum leprosum with infliximab

Faber WR, Jensema AJ, Goldschmidt WF. N Eng J Med 2006; 355: 739.

A BL patient with type 2 reaction multidrug therapy refractory to daily prednisolone 40 mg and thalidomide 300 mg responded promptly to three doses of infliximab 5 mg/kg every other week with no recurrence for 1 year after the last dose.

Leukocytoclastic vasculitis

Nicole Fett, and Jeffrey P. Callen

Vasculitis is best classified based on the size of the vessels involved. Large vessel vasculitides, giant cell arteritis and Takayasu arteritis, involve large arteries and rarely have associated cutaneous findings. Pure medium vessel vasculitides such as polyarteritis nodosa and

cutaneous polyarteritis nodosa affect vessels with muscular walls. Cutaneous features of medium vessel vasculitides include livedo reticularis, retiform purpura, nodules, ulcers, and infarcts. Vasculitides that involve both medium and small vessels include granulomatosis with polyangiitis (GPA, previously Wegener granulomatosis), eosinophilic granulomatous angiitis (EGPA, previously Churg–Strauss syndrome), and microscopic polyangiitis. Overlap medium and small vessel vasculitides may present with features of medium vessel involvement and features classic for small vessel involvement (urticaria, palpable purpura). Cryoglobulinemia can be associated with either a small vessel vasculitis or an occlusive vasculopathy and frequently is associated with hepatitis C viral infection. This condition is manifest with purpuric skin lesions usually. Lastly, pure small vessel vasculitides include IgA vasculitis (previously Henoch–Schönlein purpura [HSP]), erythema elevatum diutinum, urticarial vasculitis (UV), and cutaneous small vessel vasculitis (CSVV, previously leukocytoclastic vasculitis [LCV]). LCV is a histopathologic term that describes the pattern seen on skin biopsy and should not be used as a clinical diagnosis. The majority of patients labeled with LCV have CSVV; however, the most common cutaneous manifestations of antineutrophil cytoplasmic antibody (ANCA)–associated vasculitis is LCV, and therefore careful evaluation for systemic involvement is necessary in patients whose skin biopsies reveal LCV. CSVV is frequently secondary to exposure to medications or associated with infections. Most, perhaps roughly 60% of the time, CSVV is self-limiting.

Management Strategy

Management of small vessel vasculitis requires evaluation for systemic involvement, removal of potential causative agents or treatment directed at associated diseases, management of symptoms in those patients with self-limiting disease, and targeted or empiric therapy for patients with recurrent or recalcitrant disease. Patients with systemic vasculitis, particularly when involving the kidneys, lungs, or central nervous system, require immediate referral to rheumatology, nephrology, or other specialists and frequently require hospitalization for treatment with *systemic corticosteroids and immunosuppressive/immunomodulatory agents*.

Patients with CSVV in whom there is an identifiable cause, such as

a drug, are treated symptomatically in addition to removing the presumed causative agent. Symptomatic measures include *rest, elevation, gradient support stockings*, and *antihistamines*.

The challenge is to treat the patient who has chronic CSVV without a defined etiology and without systemic involvement. In patients with asymptomatic disease who are not bothered by the appearance of their vasculitic lesions, no treatment may be needed. For those patients who develop pain, ulcerations, or psychological distress, the risks and benefits of therapy should be discussed. Treatment recommendations for CSVV are largely based on case reports, case series, and expert opinion. If systemic therapy is considered for disease “confined to the skin,” *colchicine* and *dapsone* are first-line agents, given their relative safety.

Immunosuppressive/immunomodulatory agents including methotrexate and azathioprine have been used in patients who are refractory to colchicine and dapsone. *Systemic corticosteroids* should be avoided due to the narrow window between therapeutic effect and toxicity.

Specific Investigations

For all patients

- Careful history for drugs, preceding illness, and signs of systemic involvement
- Serologic tests for infectious diseases (hepatitis C, hepatitis B, human immunodeficiency virus)
- Complete blood count
- Comprehensive blood biochemistry
- Urinalysis
- Chest radiograph

For patients with chronic or recurrent disease

- Skin biopsy of *new* lesions
- ANCA
- Antinuclear antibody (ANA), rheumatoid factor, anti-Ro/SS-A, etc.
- Complement levels

For selected patients

- Urine toxicology screen for cocaine/levamisole

- Echocardiography
- Visceral angiography
- Malignancy screening tests

The purpose of evaluating the patient with cutaneous vasculitis is to identify a cause of the process and assess for the presence of systemic involvement. The evaluation begins with a careful history and physical examination, followed by selected testing based on the acuteness of the process and the findings from the history and physical examination. Direct immunofluorescence (DIF) is required to differentiate IgA vasculitis, which might be associated with a higher risk of renal involvement, from other causes of CSVV.

Cutaneous vasculitis in children and adults: associated diseases and etiologic factors in 303 patients

Blanco R, Martinez-Taboada VM, Rodriguez-Valverde V, Garcia-Fuentes M. *Medicine* 1998; 77: 403–18.

Diagnoses and associated diseases of 172 adults and 131 children who presented to a medical center over a 19-year period. Of the 131 children, only 1 had a secondary vasculitis. In contrast, approximately 30% of the adults had systemic involvement or secondary vasculitis. The authors therefore recommend less intensive investigations in children than in adults.

A practical approach to the diagnosis, evaluation, and management of cutaneous small-vessel vasculitis

Goeser MR, Laniosz V, Wetter DA. *Am J Clin Dermatol* 2014; 15: 299–306.

An approach to the patient with small vessel vasculitis and a very useful algorithm for evaluation and treatment.

Drug-associated cutaneous vasculitis: study of 239 patients from a single referral center

Ortiz-Sanjuán F, Blanco R, Hernández JL, Pina T, González-Vela MC, Fernández-Llaca H, et al. *J Rheumatol* 2014; 41: 2201–7.

This retrospective review spanning 36 years assessed 773 patients with a diagnosis of cutaneous vasculitis. Of these, 30.9% met the 2012 Chapel Hill Consensus Conference (CHCC) definition for drug-induced cutaneous vasculitis. Antibiotics were implicated as the causative agent in 62.3% of cases. 45.2% required systemic

immunosuppression, and 18.4% of them relapsed over 5 months. A large percentage of patients had systemic manifestations (joint 51%, gastrointestinal 38.1%, nephropathy 34.7%) and laboratory abnormalities (cryoglobulins 26%, ANAs 21.1%, anemia 18.8%, leukocytosis 24.7%, positive rheumatoid factor 17.5%), which suggests misclassification and would explain the high proportion of patients who required systemic immunosuppression and who relapsed.

Single-organ cutaneous small-vessel vasculitis according to the 2012 revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides: a study of 60 patients from a series of 766 cutaneous vasculitis cases

Loricera J, Blanco R, Ortiz-Sanjuán F, Hernández JL, Pina T, González-Vela MC, et al. Rheumatology 2015; 54: 77–82.

This retrospective review spanning 35 years assessed 766 patients with a diagnosis of cutaneous vasculitis. Of these patients, 60 (7.8%) met the 2012 CHCC definition of single-organ cutaneous small vessel vasculitis (SoCSVV). The etiology of the SoCSVV was medication related in 52% and infection related in 34%. Approximately a quarter of patients with SoCSVV were treated with systemic corticosteroids or nonsteroidal antiinflammatory drugs (NSAIDs). Complete recovery was noted in all patients within 4 months; however, 8% of them developed recurrence.

First-Line Therapies

• Observation	D
• Removal or withdrawal of the causative agent (e.g., drug)	D
• Colchicine	C
• Dapsone	C
• Nonsteroidal antiinflammatory drugs	C

Colchicine in the treatment of cutaneous leukocytoclastic vasculitis: results of a prospective, randomized controlled trial

Sais G, Vidaller A, Jucgla A, Gallardo F, Peyri J. Arch Dermatol 1995;

131: 1399–402.

Forty subjects with CSVV were randomized to receive colchicine or topical emollients. The study was powered to detect a 40% difference between groups. The study failed to detect a statistically significant difference between groups; however, the colchicine-treated group included all patients who had failed to respond to dapsone and a disproportionate amount of subjects who had failed other therapies. Thus the colchicine arm included patients with more recalcitrant disease, and this may have contributed to the negative result. It was also noted that the subjects' disease flared with withdrawal of the colchicine.

Colchicine is effective in controlling chronic cutaneous leukocytoclastic vasculitis

Callen JP. J Am Acad Dermatol 1985; 13: 193–200.

This open-label study involved 13 patients. This is the largest case series of colchicine use in CSVV.

Colchicine use in CSVV is supported by four case series. An inadvertently imbalanced randomized controlled trial (RCT) of colchicine in CSVV failed to show statistically significant improvement.

Sulfone therapy in the treatment of leukocytoclastic vasculitis. Report of three cases

Fredenberg MF, Malkinson FD. J Am Acad Dermatol 1987; 16: 772–8.

Three patients with CSVV were successfully treated with moderate doses of dapsone (100–150 mg daily).

Dapsone therapy for Henoch-Schönlein purpura: a case series

Iqbal H, Evans A. Arch Dis Child 2005; 90: 985–6.

Eight children with HSP were treated with dapsone. Cutaneous vasculitis improved within 1 week of therapy. Six relapsed when treatment was stopped and subsequently cleared with reinstitution of dapsone.

Dapsone in Henoch-Schönlein purpura

Sarma PS. Postgrad Med J 1994; 70: 464–5.

Case series of six adults with HSP treated with dapsone 100 mg daily. Four of 6 had clearance of arthritis and purpura within 1 week.

There are several single cases reporting efficacy of dapsone in CSVV and four small case series supporting its use.

The therapeutic response of urticarial vasculitis to indomethacin

Millns JL, Randle HW, Solley GO, Dicken CH. J Am Acad Dermatol 1980; 3: 349–55.

Open-label trial of 10 patients with UV treated with indometacin 25 mg three times daily to 50 mg four times daily. Six cleared within 17 days. Three had partial improvement.

Two case series report success with indometacin use.

Second-Line Therapies

• Systemic corticosteroids	A
• Azathioprine	C
• Methotrexate	C
• Ciclosporin	C
• Mycophenolate mofetil	C
• Rituximab (for cryoglobulinemic and ANCA-associated vasculitis)	A

Early prednisone therapy in Henoch-Schönlein purpura: a randomized, double-blind, placebo-controlled trial

Ronkainen J, Koskimies O, Ala-Houhala M, Antikainen M, Merenmies J, Rajantie J, et al. J Pediatr 2006; 149: 241–7.

One hundred seventy-one children with HSP were randomized to receive 1 mg/kg/day of prednisone for 2 weeks and 2 additional weeks of tapered prednisone versus placebo. The prednisone group had a statistically significant decrease in abdominal and joint pain and renal dysfunction. Prednisone did not prevent the development of renal symptoms. The authors conclude that prednisone may be used in children with HSP to treat abdominal pain, arthritis, and renal involvement.

The clinical and histopathologic spectrums of urticarial vasculitis: study of forty cases

Sanchez NP, Winkelmann RK, Schroeter AL, Dicken CH. J Am Acad Dermatol 1982; 7: 599–605.

Case series of 40 patients with UV. Thirteen of 17 patients treated with prednisone 40 mg daily or greater had complete remission or

decreased severity in clinical urticaria.

Chronic urticaria-like lesions in systemic lupus erythematosus. A review of 12 cases

O'Loughlin S, Schroeter AL, Jordon RE. Arch Dermatol 1978; 114: 879–83.

Twelve patients with systemic lupus erythematosus (SLE) and UV. Ten of 12 treated with prednisone and improved. Doses ranged from 50 mg to 10 mg daily.

A randomized placebo-controlled study supports the use of prednisone in HSP. Three case series report vasculitis clearance with prednisone in urticarial vasculitis.

The clinical spectrum and therapeutic management of hypocomplementemic urticarial vasculitis: data from a French nationwide study of fifty-seven patients

Jachiet M, Flageul B, Deroux A, Le Quellec A, Maurier F, Cordoliani F, et al. Arthritis Rheumatol 2015; 67: 527–34.

Patients were treated with many different agents, and the study is limited by the lack of untreated controls. Approximate complete response rates were 25% hydroxychloroquine, 18% colchicine, 18% dapsone, 20% corticosteroids, 45% azathioprine, 0% methotrexate, 55% mycophenolate mofetil, 80% ciclosporin, and 70% rituximab.

Azathioprine. An effective, corticosteroid-sparing therapy for patients with recalcitrant cutaneous lupus erythematosus or with recalcitrant cutaneous leukocytoclastic vasculitis

Callen JP, Spencer LV, Burruss JB, Holtman J. Arch Dermatol 1991; 127: 515–22.

An open-label trial involving six patients who had failed to respond to “less toxic” therapies.

Azathioprine therapy for steroid-resistant Henoch-Schönlein purpura: a report of 6 cases

Fotis L, Tuttle PV 4th, Baszis KW, Pepmueller PH, Moore TL, White AJ. Pediatr Rheumatol Online J. 2016 Jun 23;14(1):37. doi: 10.1186/s12969-016-0100-x.

Six children with relapsing HSP without significant renal involvement were treated with azathioprine. All patients had relapsing symptoms despite corticosteroid use. They were

successfully treated with azathioprine and were tapered off of corticosteroids. The duration of azathioprine therapy ranged from 7–21 months and no adverse events were reported.

Prednisone plus azathioprine treatment in patients with rheumatoid arthritis complicated by vasculitis

Heurkens AH, Westedt ML, Breedveld FC. Arch Intern Med 1991; 151: 2249–54.

Twenty-eight patients with rheumatoid arthritis–associated vasculitis were studied. Nine patients with severe systemic vasculitis improved with 60 mg of prednisone and 2 mg/kg/body weight of azathioprine daily. The remaining 19 patients with cutaneous vasculitis were randomized to prednisone plus azathioprine treatment versus continuation of a previous regimen. Although measures of both vasculitis and arthritis activity improved to a greater degree in the patients treated with prednisone plus azathioprine in the first 3 months of therapy, and this therapy was associated with a low incidence of relapse of vasculitis, there was not a statistically significant difference between the two treatment protocols at the end of the follow-up period.

Case reports and series, totaling 21 patients, have been published supporting the use of azathioprine. A randomized alternative-therapy–controlled trial of 19 patients with rheumatoid vasculitis failed to detect a statistically significant difference in number of vasculitic lesions.

Methotrexate in patients with moderate systemic lupus erythematosus (exclusion of renal and central nervous system disease)

Gansauge S, Breitbart A, Rinaldi N, Schwarz-Eywill M. Ann Rheum Dis 1997; 56: 382–5.

Open-label trial of methotrexate involving 22 patients with SLE. Nine of the 22 patients had vasculitis. Six of 9 had resolution of their vasculitis with methotrexate.

Methotrexate use has been reported in 13 patients with CSVV in case reports and series.

Cyclosporin A in the treatment of cutaneous vasculitis. Clinical and cellular effects

Tosca A, Ioannidou DJ, Katsantonis JC, Kyriakis KP. JEADV 1996; 6: 135–41.

Twelve patients received 5 mg/kg/day for 2 months and then 2 months of prednisone ranging from 10 to 40 mg/day. Five had complete clearance and no relapses over a follow-up time of 4 to 12 months. Six responded but then relapsed during a follow-up range of 4 to 20 months.

Treatment of complicated Henoch-Schönlein purpura with mycophenolate mofetil: a retrospective case series report

Nikibakhsh AA, Mahmoodzadeh H, Karamyyar M, Hejazi S, Noroozi M, Maccoie AA, et al. Int J Rheumatol 2010; 2010: 5. Article ID: 254316.

Six children with steroid-resistant HSP were treated with mycophenolate mofetil 30 mg/kg/day. Five had improvement in their cutaneous symptoms or were reported to have “all manifestations resolved.”

Mycophenolate mofetil is effective for maintenance therapy of hypocomplementaemic urticarial vasculitis

Worm M, Sterry W, Kolde G. Br J Dermatol 2000; 143: 1324.

Two women were initially treated with cyclophosphamide–dexamethasone and then transitioned to mycophenolate mofetil, 2 gm daily. No vasculitis flares occurred during 15 months of maintenance therapy.

Efficacy of mycophenolate is supported by one open-label trial, case reports, and series.

A randomized controlled trial of rituximab following failure of antiviral therapy for hepatitis C-associated cryoglobulinemic vasculitis

Sneller M, Hu Z, Langford CA. Arthritis Rheum 2012; 64: 835–42.

Twenty-four patients who failed to improve with antiviral therapy were randomized to rituximab versus standard immunosuppression. Ten patients in the rituximab group (83%) were in remission at study month 6, compared with 1 patient in the control group (8%) ($p < 0.001$).

A randomized, controlled trial of rituximab for treatment of severe cryoglobulinemic vasculitis

De Vita S, Quartuccio L, Isola M, Mazzaro C, Scaini P, Lenzi M, et al. Arthritis Rheum 2012; 64: 843–53.

Fifty-nine patients with CV and related skin ulcers, active glomerulonephritis, or refractory peripheral neuropathy who failed or were not candidates for antiviral therapy were randomized to receive rituximab or conventional treatment (glucocorticoids, cyclophosphamide or azathioprine, and plasma exchange). Rituximab showed statistically significant improvement over conventional treatment in all outcomes.

Retreatment regimen of rituximab monotherapy given at the relapse of severe HCV-related cryoglobulinemic vasculitis: long-term follow up data of a randomized controlled multicenter study

Quartuccio L, Zuliani F, Corazza L, Scaini P, Zani R, Lenzi M, et al. *J Autoimmun* 2015; 63: 88–93.

Retrospective evaluation of the 30 patients randomized to receive rituximab in the 2012 trial. Patients received this as monotherapy for vasculitis flares. After their initial treatment 43.3% were in complete remission and did not require additional rituximab, 56.7% required at least one retreatment with rituximab. Of those who were retreated, 66% responded to retreatment.

Efficacy of low-dose rituximab for the treatment of mixed cryoglobulinemia vasculitis: phase II clinical trial and systematic review

Visentini M, Tinelli C, Colantuono S, Monti M, Ludovisi S, Gragnani L, et al. *Autoimmun Rev* 2015; 14: 889–96.

Fifty-two patients with hepatitis C virus (HCV)-associated mixed cryoglobulinemic vasculitis were treated with low-dose rituximab (250 mg/m² twice). Response, time to relapse, and adverse events were compared with published historical controls who were treated with standard doses of rituximab (375 mg/m² given four times). No differences were found in treatment response, time to relapse, and adverse events. The use of historical controls is a significant limitation of this study.

Management of noninfectious mixed cryoglobulinemia vasculitis: data from 242 cases included in the CryoVas survey

Terrier B, Krastinova E, Marie I, Launay D, Lacraz A, Belenotti P, et al. *Blood* 2012; 119: 5996–6004.

Retrospective analysis of patients who did not have hepatitis C. Thirty percent had a connective tissue disease, 22% had B-cell

lymphoma, and 48% were essential (idiopathic). These authors compared outcomes of patients treated with rituximab plus corticosteroids, those with corticosteroids alone, and those with corticosteroids and immunosuppressive therapies. They found that those treated with rituximab were more likely to achieve complete clinical, serologic, and renal responses and were more likely to be on doses of prednisone below 10 mg/d than those treated with other regimens. However, rituximab-treated patients had more infectious complications (perhaps related to combination with high-dose corticosteroids). The mortality in the groups was identical.

Successful use of rituximab for cutaneous vasculitis

Chung L, Funke AA, Chakravarty EF, Callen JP, Fiorentino DF. Arch Dermatol 2006; 142: 1407–10.

Two women with recalcitrant CSVV, one of whom with a history of non-Hodgkin lymphoma, responded to infusions of rituximab.

Successful treatment of rheumatoid vasculitis-associated cutaneous ulcers using rituximab in two patients with rheumatoid arthritis

Hellmann M, Jung N, Owczarczyk K, Hallek M, Rubbert A. Rheumatology 2008; 47: 929–30.

These two reports document improvement with rituximab in a total of four patients, two with rheumatoid arthritis and two with a history of lymphoma.

Rituximab has become standard of care for cryoglobulinemic vasculitis refractory to antiviral therapy based on RCTs. However, with the approval of new antiviral therapies that cure hepatitis C infection in 96% to 98% of patients, additional therapies for hepatitis C–associated vasculitides may not be needed in the future. Rituximab use in CSVV is supported by case series.

Third-Line Therapies

• Antihistamines	E
• Pentoxifylline	E
• Plasma exchange	D
• Intravenous immunoglobulin (IVIG)	E
• Infliximab	E
• Tacrolimus	E

Synergistic effects of pentoxifylline and dapsone in leucocytoclastic vasculitis

Nurnberg W, Grabbe J, Czarnetzki BM. Lancet 1994; 343: 491.

Three cases of CSVV that resolved with pentoxifylline (1200 mg per day) and dapsone (100 mg per day).

Chronic leukocytoclastic vasculitis associated with polycythemia vera: effective control with pentoxifylline

Wahba-Yahav AV. J Am Acad Dermatol 1992; 26: 1006–7.

A single case improved with pentoxifylline 400 mg three times daily.

Plasma exchange in refractory cutaneous vasculitis

Turner AN, Whittaker S, Banks I, Jones RR, Pusey CD. Br J Dermatol 1990; 122: 411–5.

Eight patients with intractable CSVV were treated with plasma-exchange therapy. Seven improved.

Case report: steroid sparing effect of intravenous gamma globulin in a child with necrotizing vasculitis

Gedalia A, Correa H, Kaiser M, Sorensen R. Am J Med Sci 1995; 309: 226–8.

A 2½-year-old boy with fever, arthritis, and necrotizing CSVV was able to taper off of prednisone after intravenous γ -globulin administration.

Successful treatment of chronic leucocytoclastic vasculitis and persistent ulceration with intravenous immunoglobulin

Ong CS, Benson EM. Br J Dermatol 2000; 143: 447–9.

A 24-year-old woman with chronic ulcerating CSVV refractory to multiple immunosuppressants cleared with IVIG.

Therapy for severe necrotizing vasculitis with infliximab

Mang R, Ruzicka T, Stege H. J Am Acad Dermatol 2004; 51: 321–2.

A 62-year-old female with chronic ulcerating CSVV refractory to prednisone, IVIG, and topical tacrolimus healed with two infusions of infliximab. Unfortunately, recurrent infections limited further use. It must also be noted that tumor necrosis factor alpha therapies have also been reported to cause CSVV.

Response of deep cutaneous vasculitis to infliximab

Uthman IW, Touma Z, Sayyad J, Salman S. J Am Acad Dermatol 2005; 53: 353–4.

A 15-year-old female cleared with infliximab.

Treatment of severe and difficult cases of systemic lupus erythematosus with tacrolimus. A report of three cases

Duddridge M, Powell RJ. Ann Rheum Dis 1997; 56: 690–2.

Two of the three had clearing of CSVV.

Lichen myxedematosus

Jessica A. Kaffenberger, and Joslyn S. Kirby

Lichen myxedematosus (LM) is a rare, chronic disease characterized by infiltration of the skin with mucin-producing fibroblasts. Typical examination findings include shiny, skin-colored to erythematous papules, nodules, and plaques on the face and/or extremities. Extensive disease can cause widespread firm, thickened skin, including leonine facies. The systemic form, scleromyxedema,

can be associated with a monoclonal IgG lambda gammopathy, esophageal dysmotility, myopathy, and dermatoneuro syndrome. Localized forms do not have these associations and include acral persistent papular mucinosis, self-healing papular mucinosis, discrete LM, nodular LM, and cutaneous mucinosis of infancy.

Management Strategy

The treatment of LM remains a challenge. The absence of controlled studies makes comparison of different drugs or drug regimens difficult.

Localized forms may be observed or treated with topical medications (*steroids or calcineurin inhibitors*) or destructive therapies such as *cryotherapy, dermabrasion, or hyaluronidase*.

The systemic form, scleromyxedema, is treated more aggressively, and patients may require treatment with multiple medications. Given the association between scleromyxedema and monoclonal gammopathy, some therapies for systemic LM parallel the treatment of multiple myeloma. *Melphalan* has shown beneficial results when used alone or in combination with other therapies, including *plasmapheresis, oral prednisone, or autologous stem cell transplant*. However, melphalan use is severely limited by adverse effects, including malignancy, sepsis, and death. Other immunosuppressive agents, including *bortezomib, 2-chlorodeoxyadenosine (cladribine), cyclophosphamide, ciclosporin, methotrexate, thalidomide*, or a combination of *dexamethasone, octreotide, and sirolimus* have demonstrated some efficacy.

Alternatives to immunosuppressive agents include *intravenous immunoglobulin (IVIG), isotretinoin, interferon- α_{2b} , intralesional triamcinolone acetonide, psoralen with UVA (PUVA), and extracorporeal photochemotherapy*.

Specific Investigations

- Serum protein electrophoresis
- Tests for HIV infection
- Thyroid function testing
- Tests for hepatitis C infection

Scleromyxedema

Hummers LK. Curr Opin Rheumatol 2014; 26: 658–62.

An abnormal paraprotein, most commonly a monoclonal IgG lambda, is found in most patients (>80%) with scleromyxedema. Esophageal dysmotility can affect about 50% and myopathy about 10% to 50%. Associations with HIV and hepatitis C virus infections are rare. The cause of the disease is unknown, and it must be distinguished from thyroid-related mucinoses.

Scleromyxedema secondary to hepatitis C virus and successfully treated with antiviral therapy

Smith JA, Kalimullah FA, Erickson CP, Peng LS. Dermatol Online J 2015; 21: 9.

Small studies have associated scleromyxedema with hepatitis C infection. This appears more common in Japanese patients. A handful of cases outside Japan have been reported, including this patient who improved with ribavirin and interferon- α_{2b} .

First-Line Therapies

• Intravenous immunoglobulin	C
• Melphalan	C
• Systemic corticosteroids	D
• Plasmapheresis	D

Scleromyxedema: a case series highlighting long-term outcomes of treatment with intravenous immunoglobulin (IVIG)

Blum M, Wigley FM, Hummers LK. Medicine 2008; 87: 10–20.

Eight patients had dramatic improvement of their cutaneous and visceral disease and were subsequently maintained with IVIG.

Numerous other case reports and series, including several reports of

patients with dermatoneuro syndrome, also demonstrated skin and systemic symptom improvement with IVIG (0.5–2 g/kg). IVIG has also been shown to be beneficial in combination with several therapies, including plasmapheresis, prednisone, melphalan, and thalidomide,

Scleromyxedema

Dinneen AM, Dicken CH. J Am Acad Dermatol 1995; 33: 37–43.

A review of 17 patients treated with melphalan. Twelve of the patients revealed improvement in their cutaneous symptoms; however, eight of the patients had only temporary improvement. Ten of the treated patients died from complications of the disease or treatment.

Scleromyxedema: an experience using treatment with systemic corticosteroid and review of the published work

Lin YC, Wang HC, Shen JL. J Dermatol 2006; 33: 207–10.

A case report of successful treatment with prednisolone 0.3 mg/kg/day divided four times daily for 1 week then tapered for 3 more weeks. Other studies have successfully used prednisone 60 mg four times daily for 4 to 6 weeks with gradual taper or pulse dexamethasone. However, other reports demonstrate a mixed success rate with steroids alone. Several case reports show a benefit of combining dexamethasone with bortezomib and/or thalidomide.

Scleromyxedema with monoclonal gammopathy and neurological involvement: recovery from coma after plasmapheresis

do Prado AD, Schmoeller D, Bisi MC, Piovesan DM, Dias FS, Staub HL. Int J Dermatol 2012; 51: 1013–5.

A man with severe cutaneous and central nervous system disease (dermatoneuro syndrome) underwent three consecutive courses of plasmapheresis with remarkable neurologic improvement. There is mixed success in other case reports.

Second-Line Therapies

• Autologous stem cell transplantation	D
• Bortezomib	D
• Isotretinoin/etretinate	D
• Topical or intralesional corticosteroids	E
• Topical calcineurin inhibitors	E

Scleromyxedema: role of high-dose melphalan with autologous stem cell transplantation

Donato ML, Feasel AM, Weber DM, Prieto VG, Giralt SA, Champlin RE, et al. Blood 2006; 107: 463–6.

All seven patients survived, five had a complete remission of the skin, and visceral disease greatly improved. However, there is a report of a patient with scleromyxedema who developed dermatoneuro syndrome after autologous stem cell transplantation.

Response to bortezomib of a patient with scleromyxedema refractory to other therapies

Migkou M, Gkatzamanidou M, Terpos E, Dimopoulos MA, Kastritis E. Leuk Res 2011; 35: e209–11.

A case report of a patient with a history of numerous unsuccessful treatments treated with 21-day cycles of bortezomib 1.3 mg/m² on days 1, 4, 8, and 11 and dexamethasone 40 mg on days 1 to 4. The patient experienced sensory peripheral neuropathy after the second cycle, so the bortezomib dose was reduced to 1 mg/m². Eight cycles of bortezomib with dexamethasone were completed with near resolution at 24 months.

Treatment of recalcitrant scleromyxedema with thalidomide in 3 patients

Sansbury J, Cocuroccia B, Jorizzo J, Gubinelli E, Gisondi P, Girolomoni G. J Am Acad Dermatol 2004; 51: 126–31.

Three patients had marked improvement of cutaneous lesions, joint mobility, and reduction of paraprotein levels. Several successful cases of thalidomide (50–400 mg/day) were reported, including in

combination with other therapies such as IVIG, dexamethasone, and chemotherapeutic agents.

Generalized papular and sclerodermoid eruption: scleromyxedema

Serdar ZA, Altunay IK, Yasar SP, Erfan GT, Gunes P. Indian J Dermatol Venereol Leprol 2010; 76: 592.

A report of scleromyxedema improving with isotretinoin 60 mg daily for 6 months. Previous case reports of scleromyxedema treated with isotretinoin demonstrate mixed results.

Nodular-type lichen myxedematosus: a case report

Ogita A, Higashi N, Hosone M, Kawana S. Case Rep Dermatol 2010; 2: 195–200.

A case report of a complete response to intralesional triamcinolone acetonide for nodular-type lichen myxedematosus. Other case reports showed mixed results with topical or intralesional steroids.

Treatment of localized lichen myxedematosus of discrete type with tacrolimus ointment

Rongioletti F, Zaccaria E, Cozzani E, Parodi A. J Am Acad Dermatol 2008; 58: 530–52.

Two patients with near-complete resolution of lichen myxedematosus with twice-daily application for 8 weeks. One patient did not respond to topical steroids.

Third-Line Therapies

• Allogeneic stem cell transplantation	E
• Cyclophosphamide	E
• Ciclosporin	E
• Dexamethasone + octreotide + sirolimus	D
• Methotrexate	E
• Extracorporeal photopheresis	E
• PUVA	E
• Radiation	E
• Vincristine	E

Allogenic stem cell transplantation for the treatment of refractory scleromyxedema

Shayegi N, Alakel N, Middeke JM, Schetelig J, Mantovani-Loffler L, Bornhauser M. Transl Res 2015; 165: 321–4.

A patient with scleromyxedema associated with severe neurologic involvement continued to relapse despite numerous therapies, including autologous stem cell transplant. A rapid clinical remission occurred after allogeneic hematopoietic stem cell transplant from a sibling.

Scleromyxedema with subclinical myositis

Prasad PV, Joseph JM, Kaviarasan PK, Viswanathan P. Indian J Dermatol Venereol Leprol 2004; 70: 36–8.

A case report of a patient with scleromyxedema and myositis treated with cyclophosphamide 50 mg twice a day and prednisolone 40 mg/day. The patient had a 75% improvement at 1 month.

Successful treatment of intractable scleromyxedema with cyclosporin A

Saigoh S, Tashiro A, Fujita S, Matsui M, Shibata S, Takeshita H, et al.

Dermatol 2003; 207: 410–1.

After failing PUVA, oral prednisone, and plasmapheresis, a patient's condition improved with ciclosporin at doses of 50 to 100 mg/day. There was a 50% improvement at 4 months and near resolution at 18 months.

Scleromyxedema: a novel therapeutic approach

El-Darouti MA, Hegazy RA, Fawzy MM, Mahmoud SB, Dorgham DA. J Am Acad Dermatol 2013; 69: 1062–6.

Five cases of scleromyxedema were successfully treated with 6 months of combination therapy of dexamethasone 120 mg intramuscularly over 2 consecutive days per week, octreotide 200 µg subcutaneous every other day, and oral sirolimus 1 g BID. Sirolimus was continued for an additional 6 months.

Arndt Gottron scleromyxedema: successful response to treatment with steroid minipulse and methotrexate

Mehta V, Balachandran C, Rao R. Indian J Dermatol 2009; 54: 193–5.

A single report of a patient who had over 75% improvement in cutaneous induration after treatment with minipulses of betamethasone 3 mg twice weekly and methotrexate 10 mg weekly.

Cutaneo-systemic papulosclerotic mucinosis (scleromyxedema): remission after extracorporeal photochemotherapy and corticoid bolus

D'Incan M, Franck F, Kanold J, Bacin F, Achin R, Beyvin AJ, et al. Ann Dermatol Venereol 2001; 128: 38–41.

A complete cutaneous therapeutic response was obtained in one patient after 12 extracorporeal photopheresis courses and four pulse treatments of prednisolone.

Scleromyxedema: treatment of widespread cutaneous involvement by total skin electron-beam therapy

Rampino M, Garibaldi E, Ragona R, Ricardi U. Int J Dermatol 2007; 46: 864–7.

The report of one patient successfully treated with radiation therapy and a review of previous reports.

Vincristine, idarubicin, dexamethasone and thalidomide in scleromyxoedema

Laimer M, Namberger K, Massone C, Koller J, Emberger M, Pleyer L, et al. *Acta Derm Venereol* 2009; 89: 631–5.

A case report of a patient treated with the chemotherapeutic regimen of vincristine, idarubicin, and dexamethasone (VID regimen) in addition to daily oral thalidomide that led to clinical and laboratory remission in 12 weeks.

Lichen nitidus

Andrew L. Wright

Lichen nitidus is an uncommon idiopathic condition presenting with 1- to 2-mm-diameter flat-topped or domed papules. They usually remain discrete but may be grouped. They can occur on any part of the body but mainly affect the forearms, penis, abdomen, chest, and buttocks. Palmar lesions may be hemorrhagic.

Management Strategy

Lichen nitidus persists for long periods but is generally asymptomatic, and *treatment may not be necessary*. No large controlled clinical trials have been reported; most treatments are based on anecdotal reports.

In patients with localized disease, *potent topical corticosteroids* and *topical tacrolimus* can be successful in clearing lesions. For more extensive disease *phototherapy* (psoralen plus UVA [PUVA] and UVB) has been reported to be successful. *Antihistamines*, including *astemizole* and *cetirizine*, are reported to have cleared lesions. Generalized lesions have cleared with *PUVA*, *UVB*, and *acitretin*.

Specific Investigation

- Biopsy

First-Line Therapies

• Topical corticosteroids	E
• UVB	D

Successful treatment of lichen nitidus

Wright S. Arch Dermatol 1984; 120: 155–6.

A 24-year-old woman with a 12-year history of extensive lesions cleared with 1 month's treatment using 0.05% fluocinonide cream twice daily. No recurrence was noted at 12-month follow-up.

Treatment of generalized lichen nitidus with narrow band ultraviolet light

Park JH, Choi YL, Kim WS, Lee DY, Yang JM, Lee ES, et al. J Am Acad Dermatol 2006; 54: 545–6.

A 33-year-old man with a 3-year history of generalized disease was

reported as almost clear after 28 treatments and remained clear 11 months after cessation of therapy. A 10-year-old with generalized disease was reported as completely clear after 41 treatments and was clear at the 6-month follow-up.

Two cases of generalized lichen nitidus treated successfully with narrow band UVB phototherapy

Kim YC, Shim SD. Int J Dermatol 2006; 45: 615–7.

A 7-year-old girl and a 10-year-old boy, both with generalized lichen nitidus, were treated with narrowband UVB phototherapy, receiving between 17 and 30 treatments with maximum 9.5 J/cm². Both were reported as almost clear at the end of treatment and remained clear for at least 11 months.

A case of generalized lichen nitidus successfully treated with narrow-band ultraviolet B treatment

Bilgili SG, Karadag AS, Calka O, Ozdemir S, Kosem M.

Photodermatol Photoimmunol Photomed 2013; 29: 215–7.

A 15-year-old girl with generalized lichen nitidus was treated with 25 sessions of UVB over a 2-month period with complete clearance.

Second-Line Therapies

• Topical tacrolimus	E
• Antihistamines	D
• PUVA	E
• Oral retinoids	E
• Ciclosporin	E
• Topical pimecrolimus	E

Lichen nitidus treated with topical tacrolimus

Dobbs CR, Murphy SJ. J Drugs Dermatol 2004; 3: 683–4.

A 32-year-old man with lichen nitidus confined to the penis was treated with twice-daily tacrolimus 0.1%. The lesion was reported to be clear after 4 weeks' treatment and had not relapsed after 4 months.

Generalised lichen nitidus: a report of two cases treated with astemizole

Ocampo J, Torne R. Int J Dermatol 1989; 28: 49–51.

Two patients treated with astemizole, a 65-year-old man with a 3-month history and a 48-year-old woman with a 4-month history, were either cleared or dramatically improved with 6 to 12 days of astemizole 10 mg daily.

Lichen nitidus treated with astemizole

Thio HB. Br J Dermatol 1993; 129: 342.

A 20-year-old woman with widespread disease responded to astemizole 10 mg daily after relapsing after a successful course of PUVA. There was no recurrence of lesions at 2-year follow-up.

It should be noted that astemizole has been discontinued because of

cardiotoxicity noted with certain drug interactions. It is presumed that safer antihistamines might also be valuable.

Treatment of generalized lichen nitidus with PUVA

Randle HW, Sander HM. Int J Dermatol 1986; 25: 330–1.

A 29-year-old woman with an 8-month history of a generalized eruption was treated with PUVA three times weekly. Lesions cleared after 46 treatments (290 J) and remained clear 5 years later.

Association of lichen planus and lichen nitidus – treatment with etretinate

Aram H. Int J Dermatol 1988; 27: 117.

A 35-year-old woman with a 4-month history cleared with 8 weeks of etretinate 25 mg/50 mg on alternate days. Treatment was stopped 1 month later. There was no recurrence 5 months after completing the treatment.

Treatment of palmoplantar lichen nitidus with acitretin

Lucker GPH, Koopman RJJ, Steijlen PM, Van der Valk PG. Br J Dermatol 1994; 130: 791–3.

A 23-year-old man had a 14-month history of hand and foot involvement that failed to clear with acitretin 50 mg daily but was reported to have improved significantly on 75 mg daily.

A case of generalized lichen nitidus treated with low dose cyclosporine

Lee YK, Choi KW, Lee CW, Kim KH. Korean J Dermatol 2007; 45: 1311–4.

A 16-year-old girl with generalized lichen nitidus was significantly improved with 8 weeks of ciclosporin 2 mg/kg/day.

Generalized lichen nitidus successfully treated with pimecrolimus 1% cream

Farshi S, Mansouri P. Dermatol Online J 2011; 17: 11.

Lesions were reduced and flattened after treatment twice daily for 8 weeks.

Generalized lichen nitidus: successful treatment with systemic isotretinoin

Topal IO, Gokdemir G, Sahin IM. Indian J Dermatol Venereol Leprol

2013; 79: 554.

A 15-year-old female patient cleared completely with 4 months of isotretinoin 40 mg daily.

Third-Line Therapies

• Itraconazole	E
• Dinitrochlorobenzene	E
• Cetirizine dihydrochloride and levamisole	E
• Isoniazid	E

Treatment of lichen planus and lichen nitidus with itraconazole: reports of six cases

Libow LF, Coots NV. *Cutis* 1998; 62: 247–8.

A report of two cases showing partial clearance of lichen nitidus after 2 weeks of itraconazole 200 mg twice daily.

Improvement of lichen nitidus after topical dinitrochlorobenzene application

Kano Y, Otake Y, Shiohara T. *J Am Acad Dermatol* 1998; 39: 305–8.

This paper reports a patient treated with 0.1% dinitrochlorobenzene (DNCB) applied at 2-weekly intervals after sensitization with 1% DNCB. The lesions were said to have cleared after 7 months of treatment, compared with a control area. Six months after cessation of treatment, lesions were said to be recurring in the treated area.

Generalised lichen nitidus in a child: response to cetirizine dihydrochloride/levamisole

Sehgal VN, Jain S, Kumar S, Bhattacharya SN, Singh N. *Australas J Dermatol* 1998; 39: 60.

A 6-year-old boy with a 6-month history of generalized involvement showed complete regression/healing of lesions over a 4-week period of treatment with cetirizine dihydrochloride 5 mg daily and levamisole 50 mg on alternate days for 4 weeks.

Generalised lichen nitidus is successfully treated with an antituberculous agent

Kubota Y, Kirya H, Nakayama J. Br J Dermatol 2002; 146: 1081–3.

A 10-year-old Japanese girl with a 2-year history of lichen nitidus showed almost complete clearance after a 6-month course of oral isoniazid.

Facial actinic lichen nitidus successfully treated with hydroxychloroquine: a case report

Bouras M, Benchikhi H, Ouakkadi A, Zamiati S. Dermatol Online J 2013; 19: 20406.

Treatment with a combination of topical steroids and hydroxychloroquine produced complete clearance in 4 weeks in a 23-year-old female with facial lichen nitidus.

Lichen planopilaris

Anwar Al Hammadi, and Eric Berkowitz

Lichen planopilaris (LPP), also known as *follicular lichen planus*, is a clinical syndrome consisting of lichen planus (LP) associated with cicatricial scalp alopecia. The condition is more common in women and presents with perifollicular erythema and keratotic plugs at the margins of the expanding alopecia. The follicular involvement is limited to the infundibulum and the isthmus, both demonstrating lichenoid inflammation. The main complications of follicular LP are

atrophy and scarring, with permanent hair loss. Three forms of LPP are recognized: classic LPP; Graham–Little syndrome, characterized by the triad of multifocal scalp cicatricial alopecia, nonscarring alopecia of the axilla and/or groin, and keratotic follicular papules; and frontal fibrosing alopecia that affects mainly postmenopausal women and appears as cicatricial alopecia of the frontoparietal hairline and is associated with nonscarring alopecia of the eyebrows.

Management Strategy

Therapeutic management for LPP is challenging. However, if the associated inflammation can be controlled in its early stages, follicular units may be preserved and hair regrowth may be possible. A good therapeutic response would include a reduction in associated symptoms along with stabilization of the disease and some regrowth of hair in the active perimeter of the alopecic patch. For the most part, therapeutic reports are anecdotal. *Oral antihistamines* may be used to control pruritus, and *high-potency topical corticosteroids* are used to control the inflammation in early lesions. *Intralesional injections of 3 to 5 mg/mL of triamcinolone acetonide* are effective in well-developed lesions. *Hydroxychloroquine* may be efficacious. *Retinoids* have demonstrated some effect in the treatment of LP and therefore provide a possible alternative to corticosteroid treatment. Other agents that have been reported to be of use are *cyclosporine* and *mycophenolate mofetil*. There is some rationale for trying biologic agents such as tumor necrosis factor (TNF)–blocking agents for this condition.

Specific Investigations

- Skin biopsy
- Immunofluorescence studies
- Dermoscopy

A histologic review of 27 patients with lichen planopilaris

Tandon YK, Somani N, Bergfeld WF. J Am Acad Dermatol 2008; 59: 91–8.

Characteristic features of LPP include the absence of arrector pili muscles and sebaceous glands, a perivascular and perifollicular

lymphocytic infiltrate, mucinous perifollicular fibroplasia with absence of interfollicular mucin, and superficial perifollicular wedge-shaped scarring.

Immunofluorescence abnormalities in lichen planopilaris

Ioannides D, Bystryn JC. Arch Dermatol 1992; 128: 214–6.

Direct immunofluorescence studies were performed on biopsied lesions of patients with LPP and LP. All of the LPP studies demonstrated abnormal linear deposits of immunoglobulin, consisting of IgG or IgA restricted to the basement membrane. The biopsies from those with LP demonstrated fibrillar deposits.

These different appearances suggest different disease processes for LPP and LP.

Dermatoscopy: alternative uses in daily clinical practice

Micali G, Lacarrubba F, Massimino D, Schwartz R. J Am Acad Dermatol 2011; 64: 1135–46.

Video dermatoscopy is performed with a video camera equipped with lenses providing magnification ranging from $\times 10$ to $\times 1000$ and shows the reduction to total absence of orifices, hyperkeratotic perifollicular scales, and erythema. In addition, perifollicular arborizing vessels, pigmented networks, and white pale or blue-gray dots in dark-skinned individuals, corresponding to focal decrease in melanin content, can also be observed.

The use of anti-keratin 903 antibodies to visualize colloid bodies and diagnose lichen planopilaris

Lanoue J, Yanofsky VR, Mercer SE, Phelps RG. Am J Dermatopathol 2016; 38: 353–8.

CK-903 is a useful adjunctive tool that will allow for a quicker, less costly, and more accurate diagnosis of LPP given its ability to identify colloid bodies even in the setting of significant inflammation and fibrosis and its advantages over direct immunofluorescence of low cost, short preparation time, and lack of need for a specialized fluorescent microscope.

First-Line Therapies

• High-potency corticosteroids	D
• Intralesional corticosteroids	C

Lichen planopilaris: report of 30 cases and review of the literature

Chieregato C, Zini A, Barba A, Magannini M, Rosina P. Int J Dermatol 2003; 42: 342–5.

This clinical trial reports good therapeutic benefit from early treatment with high-potency topical steroids. Only four patients did not respond to the therapy and needed other treatments.

Scarring alopecia

Newton RC, Hebert AA, Freese TW, Solomon AR. Dermatol Clin 1987; 5: 603–18.

High-potency topical corticosteroids may be used to control inflammation in early scalp lesions. Intralesional injections with triamcinolone acetonide at concentrations of 3 to 5 mg/mL are more effective in well-developed lesions. Additionally, oral corticosteroids have been used in short tapering dosages to control severe disease.

Second-Line Therapies

• Oral corticosteroids	C
• Retinoids	C
• Antimalarials	C
• Tetracycline	D

Postmenopausal frontal fibrosing alopecia: a frontal variant of lichen planopilaris

Kossard S, Lee MS, Wilkinson B. J Am Acad Dermatol 1997; 36: 59–66.

Oral corticosteroids and antimalarials were found to slow the course of LPP.

Lichen planopilaris: clinical and pathologic study of forty-five patients

Mehregan DA, Van Hale HM, Muller SA. J Am Acad Dermatol 1992; 27: 935–42.

This large study of 45 patients involved multiple different therapeutic modalities. High-potency topical steroids and oral steroids (30–40 mg daily) for 3 months demonstrated the highest success rates.

Oral treatment of keratinizing disorders of skin and mucous membranes with etretinate. Comparative study of 113 patients

Mahrle G, Meyer-Hamme S, Ippen H. Arch Dermatol 1982; 118: 97–100.

This paper reports the comparative results of the effects of the aromatic retinoid etretinate on various skin disorders.

Retinoids have been found to have a significant impact in cases of LP and have therefore been tried with some success in cases of LPP. Isotretinoin may be preferred over acitretin, as the latter agent has been associated with hair loss, but long-term therapy with low-dose acitretin has been studied in psoriasis and is well tolerated.

A case-series of 29 patients with lichen planopilaris. The Cleveland Clinic Foundation experience on evaluation, diagnosis, and treatment

Cevasco NC, Bergfeld WF, Remzi BK, de Knott HR. J Am Acad Dermatol 2007; 57: 47–53.

In this retrospective study of 29 patients, researchers found that the most commonly prescribed treatments for the reduction of primary symptoms associated with LPP were ketoconazole shampoo (86%), topical steroids (83%), multivitamins with minerals (76%), intralesional steroids (69%), topical minoxidil (41%), and tetracycline (38%). The most common treatment combination was topical steroid,

ketoconazole shampoo, tetracycline, and multivitamins with minerals (14%).

Although patient response to any of these therapies was minimal, tetracycline (1 g/day) was the only treatment associated with a significant number of positive responses (6 of 11 patients).

Hydroxychloroquine and lichen planopilaris: efficacy and introduction of Lichen Planopilaris Activity Index scoring system

Chiang C, Sah D, Cho BK, Ochoa BE, Price VH. J Am Acad Dermatol 2010; 62: 387–92.

This retrospective study of 40 adult patients showed significant efficacy of hydroxychloroquine in the treatment of LPP. After 6 months, 69% of patients (26 of 38) were full or partial responders. After 12 months, 83% of patients (33 of 40) were full or partial responders. Of the nine responders at 12 months, six were able to discontinue hydroxychloroquine and had a sustained remission with no systemic medication for at least 1 year.

Third-Line Therapies

• Mycophenolate mofetil	D
• Cyclosporine	D
• Tacrolimus	E
• Thalidomide	E
• TNF-blocking drugs	E
• Low-dose excimer 308-nm laser	D
• Pioglitazone	D

Efficacy and safety of mycophenolate mofetil for lichen

planopilaris

Cho BK, Sah D, Chwalek J, Roseborough I, Ochoa B, Chiang C, et al. J Am Acad Dermatol 2010; 62: 393–7.

In this retrospective study of 16 adult patients mycophenolate mofetil was effective at reducing the signs and symptoms of active LPP in 83% of patients (10 of 12 completers) who had failed multiple prior treatments after at least 6 months of treatment. Five of 12 patients were complete responders, 5 of 12 patients were partial responders, and 2 of 12 patients were treatment failures. Four patients withdrew from the trial because of adverse events.

Short course of oral cyclosporine in lichen planopilaris

Mirmirani P, Willey A, Price V. J Am Acad Dermatol 2003; 49: 667–71.

The authors present three patients with recalcitrant LPP unresponsive to hydroxychloroquine, high-potency topical steroids, and intralesional steroids who were treated with cyclosporine. The duration of treatment ranged from 3 to 5 months, with resolution of symptoms, no progression of hair loss, and no evidence of disease activity. One of the patients had a mild recurrence, which resolved with topical 0.1% tacrolimus in Cetaphil lotion.

Thalidomide-induced remission of lichen planopilaris

Boyd AS, King LE Jr. J Am Acad Dermatol 2002; 47: 967–8.

The authors describe the case of a patient who was diagnosed with LPP and treated with hydroxychloroquine, azathioprine, isotretinoin, cyclophosphamide, dapson, cyclosporine, levamisole, chloroquine, acitretin, methotrexate, clofazimine, and enoxaparin, all without any benefit. The patient was then started on thalidomide 50 mg orally twice a day, with resolution of the symptoms. Side effects limited the ability to continue the medication. Initially, the patient only complained of fatigue and constipation; however, at 4 months, mild numbness and tingling of the fingers and toes developed, and the patient experienced significant depression, necessitating discontinuation of the medication.

Thalidomide's mechanism of action in this disorder may involve TNF inhibition, suggesting that medications such as adalimumab, etanercept, or infliximab may be beneficial. There has, however, been a case report of LPP developing in a patient treated with etanercept.

Low-dose excimer 308-nm laser for treatment of lichen

planopilaris

Navarini AA, Kolios AG, Prinz-Vavricka BM, Haug S, Trüeb RM. Arch Dermatol 2011; 147: 1325–6.

In this small study of 13 patients with biopsy-proven active classic LPP or variants, pruritus and pain improved in all patients who had these complaints before the treatment. Erythema reduced in five patients and decreased inflammatory lesions in seven patients. An increased growth of hair after 4 to 8 weeks was observed in three patients, with stable remission in two patients.

Lichen planopilaris treated with a peroxisome proliferator-activated receptor γ -agonist

Mirmirani P, Karnik P. Arch Dermatol 2009; 145: 1363–6.

A 47-year-old man with LPP recalcitrant to therapy responded to pioglitazone at a dose of 15 mg/day.

Because of the theoretical basis for the use of peroxisome proliferator-activated receptor (PPAR) agonists in LPP, further studies are warranted to determine whether this treatment is genuinely efficacious for the disorder.

The use of oral pioglitazone in the treatment of lichen planopilaris

Mesinkoyska NA, Tellez A, Dawes D, Piliang M, Bergfeld W. J Am Acad Dermatol 2015; 72: 355–6.

Retrospective case analysis of the 22 patients who were prescribed pioglitazone hydrochloride for at least 1 month, and clinical follow-up longer than 3 months showed that pioglitazone was effective in controlling the symptoms, inflammation, and disease progression in 16 patients (72.7% of the patients). Moreover, new hair regrowth was noted in six patients (27.3%). From the responders, only two patients (9%) experienced relapse after discontinuation of pioglitazone.

Lichen planus

Roselyn Kellen, and Mark G. Lebwohl

Lichen planus is a pruritic papulosquamous disease with characteristic histopathologic and clinical features. Classically, lesions are described with the 6 “P’s”: purple, pruritic, planar, polygonal, papule, and plaque. In some patients, fine white lines are visible across the surface of the lesions, known as *Wickham striae*. Oral erosive lichen planus, a painful erosive condition affecting mucous membranes, is addressed in a separate chapter.

Management Strategy

Although lichen planus can resolve spontaneously, treatment is often

required because pruritus can be severe and interfere with sleep and quality of life. An association with underlying diseases such as hepatitis C is still controversial. Physicians should obtain a detailed medical history, as there are numerous reports of lichen planus or lichenoid eruptions occurring after vaccinations, particularly hepatitis B, and after the use of certain medications.

In patients with localized disease, *superpotent corticosteroids* should be applied twice daily for 2 to 4 weeks. If the response is inadequate, *intralesional injection of corticosteroids* into localized lesions may be beneficial. Topical antipruritic agents containing *menthol, phenol, camphor, lidocaine, pramoxine, or doxepin hydrochloride* can be useful. *Oral antihistamines* may offer limited benefit in severely pruritic patients. Sedating antihistamines can be helpful at bedtime.

Traditionally, patients with extensive lichen planus have been treated with systemic corticosteroids. *Oral prednisone* 30 to 60 mg daily for 2 to 6 weeks, or its equivalent, tapered over the ensuing 2 to 6 weeks, is often effective. Unfortunately, even in patients who clear with systemic corticosteroids, relapses are frequent. If patients require more than two courses of high-dose systemic corticosteroids over the span of a few months, alternative treatments should be sought. Fortunately, there is evidence in the literature for steroid-sparing treatments, including several agents that have been studied in clinical trials.

Oral metronidazole has emerged as a safe and effective alternative to systemic corticosteroids: 500 mg twice daily for 20 to 60 days has proved beneficial in many patients. *Sulfasalazine* has been studied in a randomized, double-blind trial. Patients are started on 500 mg twice daily, and the dosage is increased by 500 mg every 3 days until a dose of 2.5 g daily is reached, for a total of 3 to 6 weeks. The use of *narrowband ultraviolet B* three times a week for 6 weeks has helped patients achieve partial and complete remission. *PUVA (Psoralen + UltraViolet A)* has been particularly beneficial in the lichen planus–like eruption associated with graft-versus-host disease. However, in one retrospective study, the recurrence rate was higher in patients who received PUVA compared with narrowband UVB. *Isotretinoin* in doses of 10 mg orally twice daily for 2 months has been reported to clear lichen planus in several patients, and *acitretin* 30 mg daily has also resulted in marked improvement or remission.

More recent studies have supported the evidence for certain therapies or evaluated the use of new agents. *Oral methotrexate* (15

mg/week for adults and 0.25 mg/kg/week for children) has helped patients achieve complete remission after 24 weeks, with most side effects reported as mild. The use of subcutaneous *enoxaparin* (5 mg weekly for 8 weeks) enabled more patients to achieve complete remission compared with the use of oral prednisone (0.5 mg/kg). *Apremilast* (20 mg twice daily for 12 weeks) has helped some patients improve their Physician Global Assessment score and maintain this improvement for 4 weeks after treatment.

For *severe and refractory lichen planus* unresponsive to other therapies, *antimicrobials* (antibiotics, antifungals), immunosuppressive agents (*mycophenolate mofetil*, *azathioprine*, *ciclosporin*, *antimalarials*), *tumor necrosis factor (TNF) blockers* (*adalimumab*), *thalidomide*, *topical calcineurin inhibitors*, *vitamin D analogs*, and *alitretinoin* have been used with success in some patients.

Palmoplantar lichen planus has been successfully treated with *acitretin* 35 mg/day (0.5 mg/kg) for 2 months, *UVA-1 laser therapy* three times a week for 4 weeks (100 J/cm²), and *ciclosporin* 3.5 mg/kg daily.

For *nail lichen planus*, there are case reports detailing the use of 30 mg *alitretinoin* daily, *ciclosporin* 3 mg/kg daily, and *etanercept* (25 mg subcutaneous twice a week for 6 months and then 50 mg weekly).

Specific Investigations

- Detailed medication history
- Liver function tests
- Serology for hepatitis B and C

Hepatitis C virus infection and lichen planus: a systematic review with meta-analysis

Lodi G, Pellicano R, Carrozzo M. *Oral Dis* 2010; 16: 601–12.

This meta-analysis included 33 studies that compared the prevalence of hepatitis C in patients with lichen planus and 6 studies that reported on the prevalence of lichen planus in patients with hepatitis C. Among patients with lichen planus, the odds ratio of being seropositive for hepatitis C was 4.85. Among patients with hepatitis C, the odds ratio of having lichen planus was 4.47.

There is conflicting data regarding the association between lichen planus and hepatitis C. This may be partially explained by geographic location and rates of hepatitis infection, genetic factors, the age of patients included in

studies, and the size of previous studies.

Drug-induced lichen planus

Thompson DF, Skaehill PA. Pharmacotherapy 1994; 14: 561–71.

β -Blockers, methyldopa, penicillamine, quinidine, quinine, and nonsteroidal antiinflammatory agents play a role in the development of lichen planus. There is insufficient evidence to implicate angiotensin-converting enzyme inhibitors, sulfonyleurea agents, carbamazepine, gold, lithium, and other drugs.

Many drugs and chemicals have been associated with lichenoid drug eruptions, which can be difficult to distinguish from true lichen planus. In addition to those mentioned here, hepatitis B and influenza vaccinations, allopurinol, tetracyclines, furosemide, hydrochlorothiazide, isoniazid, phenytoin, and etanercept are reported to cause lichenoid eruptions.

First-Line Therapies

• Topical corticosteroids	C
• Intralesional corticosteroids	D
• Antihistamines	C

Betamethasone-17,21-dipropionate ointment: an effective topical preparation in lichen rubra planus

Bjornberg A, Hellgren L. Curr Med Res Opin 1976; 4: 212–7.

Patients with lichen planus that had become resistant to betamethasone valerate ointment were treated with betamethasone dipropionate ointment once or twice daily for 2 to 3 weeks. Fourteen of 19 patients achieved better improvement with betamethasone dipropionate ointment.

Although topical and intralesional corticosteroids are first-line treatments for lichen planus, their use has been based on anecdotal reports rather than on controlled clinical trials. This is one of very few comparative trials of topical therapies for lichen planus.

Treatment of generalized cutaneous lichen planus with dipropionate and betamethasone disodium phosphate: an open study of 73 cases

Pitche P, Saka B, Kombate K, Tchangai-Walla K. Ann Dermatol Venereol 2007; 134: 237–40.

Injections of systemic corticosteroids performed at 2-week intervals resulted in complete remission in 61 of 73 (83.6%) patients with lichen planus; 8.2% of patients experienced partial remission, and another 8.2% failed this therapy. At 3 months, the relapse rate of initial responders was 23.3% and at 6 months 31.5% had relapsed.

Second-Line Therapies

• Metronidazole	B
• Sulfasalazine	A
• Systemic corticosteroids	B
• Isotretinoin, acitretin	A
• Narrowband or broadband UVB	B
• PUVA	C
• Methotrexate	B

Efficacy of oral metronidazole in treatment of cutaneous and mucosal lichen planus

Rasi A, Behzadi AH, Davoudi S, Rafizadeh P, Honarbakhsh Y, Mehran M, et al. J Drugs Dermatol 2010; 9: 1186–90.

Forty-nine patients participated in this open trial of oral metronidazole 250 mg every 8 hours for 12 weeks. Twenty patients (40.82%) had a complete response and 16 (32.65%) a partial response. Thirteen (26.53%) did not improve.

Metronidazole has also been studied in a dose of 500 mg twice daily for 20 to 60 days. The safety of oral metronidazole has led many dermatologists to use this treatment as first-line therapy for lichen planus.

Efficacy of sulfasalazine in the treatment of generalized lichen planus: randomized double-blinded clinical trial on 52 patients

Omidian M, Ayoobi A, Mapar MA, Feily A, Cheraghian B. J Eur Acad Dermatol Venereol 2010; 24: 1051–4.

Forty-four patients completed a double-blind study of sulfasalazine or placebo taken for 3 to 6 weeks. Sulfasalazine doses were started at 1 g per day and increased by 0.5 g every 3 days until a dosage of 2.5 g daily was achieved. Study medications were continued for 3 to 6 weeks. After 6 weeks of treatment, 19 patients (82.6%) in the sulfasalazine group achieved improvement compared with 2 patients (9.6%) in the placebo group. Pruritus improved in 14.3% of placebo patients and 91.3% in sulfasalazine-treated patients. Mild response (<50% of lesions cleared) occurred in 21.7% of patients in the sulfasalazine group, moderate response (>50% of lesions cleared) in 52.2%, and excellent clearing of lesions (>80%) in 8.7%.

Gastrointestinal upset and headache were the most common side effects and occurred in 30.7% of patients, leading three patients to leave the study. Mild skin rash also occurred in one patient.

Although complete clearing occurred in a minority of patients, the authors did not continue this study beyond 6 weeks. Perhaps longer therapy would result in greater rates of clearing.

Treatment of lichen planus with acitretin. A double-blind, placebo-controlled study in 65 patients

Laurberg G, Geiger JM, Hjorth N, Holm P, Hou-Jensen K, Jacobsen KU, et al. J Am Acad Dermatol 1991; 24: 434–7.

Acitretin resulted in marked improvement or remission in 64% of patients compared with 13% of placebo-treated patients in a double-blind trial in 65 subjects. Acitretin doses of 30 mg daily were used, leading to mucocutaneous side effects (dryness of the mouth, lips, nose, and skin and hair loss) and hyperlipidemia.

Isotretinoin in doses of 10 mg orally twice daily has been effective in the treatment of oral lichen planus, and anecdotal use suggests efficacy in generalized lichen planus as well. A recent case report described a patient with palmoplantar lichen planus that cleared after 2 months of acitretin 35mg/kg/day (0.5 mg/kg). The latter isotretinoin regimen has fewer

mucocutaneous side effects than higher doses of acitretin. Restrictions on the use of isotretinoin in the United States may make this less practical.

Comparison of the narrow band UVB versus systemic corticosteroids in the treatment of lichen planus: a randomized clinical trial

Iraji F, Faghihi G, Asilian A, Siadat AH, Larijani FT, Akbari M. J Res Med Sci 2011; 162: 1578–82.

In this randomized clinical trial, 46 patients were administered either prednisolone 0.3 mg/kg for 6 weeks ($n = 23$) or narrowband UVB (nbUVB) three times a week for 6 weeks ($n = 23$) with a maximum dose of 9 J/cm². More patients in the nbUVB group achieved complete response (12/23) compared with those in the steroid group (3/23) ($p < 0.05$). No side effects were reported.

Several other retrospective studies highlight the efficacy of UVB, especially nbUVB, for the treatment of generalized cutaneous lichen planus.

Psoralen plus UVA vs. UVB-311 nm for the treatment of lichen planus

Wackernagel A, Legat FJ, Hofer A, Quehenberger F, Kerl H, Wolf P. Photodermatol Photoimmunol Photomed 2007; 23: 15–9.

This retrospective chart review compared 15 patients treated with PUVA to 13 patients treated with nbUVB. Sixty-seven percent of the PUVA-treated patients achieved complete remission, and 33% achieved a partial clinical response. Thirty-one percent of patients treated with nbUVB achieved complete remission and 46% a partial response. The mean duration of therapy was 10.5 weeks for PUVA and 8.2 weeks for nbUVB, and the mean number of treatments was 25.9 PUVA treatments compared with 22.5 nbUVB treatments. Lichen planus recurred in 47% of PUVA-treated patients but only in 30% of nbUVB-treated patients.

Long-term efficacy of PUVA treatment in lichen planus: comparison of oral and external methoxsalen regimens

Helander I, Jansen CT, Meurman L. Photodermatology 1987; 4: 265–8.

Good or excellent clearing occurred in 10 of 13 patients after 8 to 46 bath-PUVA treatments, compared with 5 of 10 patients after 8 to 30 oral PUVA treatments. However, examination of patients months after PUVA suggested that treatment might prolong the duration of lichen planus.

Methotrexate for treatment of lichen planus: old drug, new indication

Kanwar AJ, De D. J Eur Acad Dermatol Venereol 2013; 27: e410–3.

Twenty-four patients with generalized lichen planus were treated with oral methotrexate (15 mg/week in adults or 0.25 mg/kg/week for children). After 2 weeks, 7 patients (30%) had at least 50% improvement in disease severity. By the end of 24 weeks, 14 patients (58%) had complete remission. Fifty percent of patients reported side effects; most were mild and only 1 patient had to discontinue therapy due to abnormal liver function tests. There were no relapses during the 3 months' follow-up.

Third-Line Therapies

• Trimethoprim–sulfamethoxazole	E
• Griseofulvin	E
• Itraconazole	C
• Terbinafine	E
• Antimalarials	E
• Tetracycline or doxycycline	C
• Ciclosporin, FK 506	E
• Mycophenolate mofetil	E
• Azathioprine	E
• Etanercept	E
• Adalimumab	E
• Interferon	E
• 0.1% tacrolimus ointment	E
• Pimecrolimus cream	E
• Alitretinoin	E
• Thalidomide	D
• UVA1	D
• Low-molecular-weight heparin	B
• Apremilast	C

Antimicrobials

Treatment of lichen planus with Bactrim

Abdel-Aal H, Abdel-Aal MA. J Egypt Med Assoc 1976; 59: 547–9.

Oral trimethoprim–sulfamethoxazole, two tablets twice daily for 5 days, cleared lichen planus within 2 weeks only to have the skin lesions relapse 2 months later. The trimethoprim–sulfamethoxazole was again effective when readministered to patients who experienced relapse.

Histopathological evaluation of griseofulvin therapy in lichen planus: a double-blind controlled study

Sehgal VN, Bikhchandani R, Koranne RV, Nayar M, Saxena HM. Dermatologica 1980; 161: 22–7.

Griseofulvin 500 mg/day for 2 months was effective in 18 of 22 patients.

Pulsed itraconazole therapy in eruptive lichen planus

Khandpur S, Sugandhan S, Sharma VK. J Eur Acad Dermatol Venereol 2009; 23: 98–101.

Sixteen patients with eruptive lichen planus were treated with itraconazole 200 mg twice daily pulsed for 1 week each month for 3 months. By the end of the first month, 9 of 16 patients (56.25%) stopped developing new lesions. Only 9 of the patients were followed for 3 months, and 7 of the 9 (77.7%) stopped developing new lesions. All of the 9 patients reported improvement of pruritus, and 5 of the 9 had complete relief of pruritus. By the end of 3 months, partial flattening was present in 6 of 9 patients (66.66%) and complete flattening in 3 (33.33%).

Given the partial response seen at 3 months, longer therapy may be warranted.

The use of oral terbinafine or topical ciclopirox for lichen planus

Click JW, Wilson BB. Cutis 2009; 84: 42.

A patient with topical corticosteroid–refractory lichen planus was treated with terbinafine 250 mg daily for 3 weeks and the lichen planus cleared. Upon recurrence of the lichen planus, the terbinafine

was again given for 3 weeks. The patient's lichen planus began to resolve within 3 days of restarting the oral terbinafine. A second patient with lichen planus was treated with ciclopiroxolamine cream for tinea pedis, and her lichen planus also resolved.

It is unclear why antifungal therapy is effective in the treatment of lichen planus, but there are numerous reports of various antifungal agents working for this condition.

Systemic immunosuppressive agents

Childhood actinic lichen planus: successful treatment with antimalarials

Ramírez P, Feito M, Sendagorta E, González-Beato M, De Lucas R. *Australas J Dermatol* 2012; 53: e10–3.

Lichen planus actinicus is a photosensitive variant that presents in sun-exposed areas of the body, including the face, V of the neck, and arms. This report documents an excellent response to hydroxychloroquine and photoprotection in an 8-year-old girl.

Successful treatment of resistant hypertrophic and bullous lichen planus with mycophenolate mofetil

Nousari HC, Goyal S, Anhalt GJ. *Arch Dermatol* 1999; 135: 1420–1.

Mycophenolate mofetil was reported to successfully treat resistant hypertrophic and bullous lichen planus.

Generalized severe lichen planus treated with azathioprine

Verma KK, Sirka CS, Khaitan BK. *Acta Derm Venereol* 1999; 79: 493.

Generalized severe lichen planus has been successfully treated with azathioprine.

Palmoplantar lichen planus with umbilicated papules: an atypical case with rapid therapeutic response to ciclosporin

Karakatsanis G, Patsatsi A, Kastoridou C, Sotiriadis D. *J Eur Acad Dermatol Venereol* 2007; 21: 1006–7.

A 63-year-old woman with lichen planus of the palms, forearms, soles, and feet was treated with ciclosporin 3.5 mg/kg daily. Pruritus improved within 2 weeks, and clinical improvement occurred within 4 weeks, at which point ciclosporin was tapered over the next 4 weeks.

In a different case report, a patient with 20 dystrophic fingernails noted improvement within 2 months of starting ciclosporin 3 mg/kg daily, but she required the addition of valsartan for hypertension.

Successful treatment of lichen planus with adalimumab

Holló P, Szakonyi J, Kiss D, Jokai H, Horváth A, Kárpáti S. *Acta Derm Venereol* 2012; 92: 385–6.

A 39-year-old woman with extensive lichen planus refractory to systemic corticosteroids, acitretin, and PUVA was treated with adalimumab 80 mg followed by 40 mg every other week. Pruritus decreased after 2 weeks, and skin lesions resolved within 2 months, leaving only hyperpigmentation.

Nail lichen planus: successful treatment with etanercept

Irla N, Schneiter T, Haneke E, Yawalkar N. *Case Rep Dermatol* 2010; 2: 173–6.

There are a number of case reports of lichen planus of the nails responding to treatment with TNF- α blockers. Unless the nail involvement is treated early, it is difficult to imagine that any therapy would reverse the pterygium that develops in late disease. There are also a number of reports of lichen planus induced by TNF- α blockers.

Other

Lichen planus and chronic hepatitis C: exacerbation of the lichen under interferon therapy

Areias J, Velho GC, Cerqueira R, Barbédo C, Amaral B, Sanches M, et al. *Eur J Gastroenterol Hepatol* 1996; 8: 825–8.

Given the association between lichen planus and hepatitis C, one might expect interferon to benefit both diseases. There are reports of interferon benefiting patients with lichen planus and exacerbating the condition in others.

Treatment of cutaneous lichen planus with thalidomide

Moura AK, Moure ER, Romiti R. *Clin Exp Dermatol* 2009; 34: 101–3.

Eight patients with cutaneous lichen planus were treated with thalidomide 100 mg daily at bedtime. Three patients withdrew because of transient neuropathy of the legs and transient weakness that began shortly after the treatment started. Five patients noted

improvement of pruritus within a few days after starting thalidomide. Skin lesions regressed in a mean of 4 weeks, and complete remission was achieved in a mean of 3 months.

Ultraviolet A1 in the treatment of generalized lichen planus: a report of 4 cases

Polderman MC, Wintzen M, van Leeuwen RL, de Winter S, Pavel S. J Am Acad Dermatol 2004; 50: 646–7.

Four patients with refractory generalized lichen planus were treated with UVA1 45 J/cm² 5 days per week for two 4-week treatment periods with a 3-week rest in between. All four improved, with one patient achieving 98% clearance.

There is also a case report detailing the treatment of palmoplantar lichen planus with UVA-1 laser therapy three times a week for 4 weeks (100 J/cm²); the patient was still symptom free 1 year later.

Topical tacrolimus in the treatment of lichen planus in a child

Fortina AB, Giulioni E, Tonin E. Pediatr Dermatol 2008; 25: 570–1.

A child with lichen planus did not respond to topical corticosteroids, but her condition resolved upon treatment with tacrolimus 0.03% ointment.

Tacrolimus 0.1% has also been used successfully to treat lichen planus in adults. In addition, case reports describe the successful use of topical pimecrolimus for cutaneous lichen planus.

Comparison of therapeutic effect of low-dose low-molecular-weight heparin (enoxaparin) vs. oral prednisone in treatment of patients with lichen planus: a clinical trial

Iraji F, Asilian A, Saeidi A, Siadat AH, Saeidi AR, Hassanzadeh A. Adv Biomed Res 2013; 2: 76.

Patients were given subcutaneous enoxaparin 5 mg weekly ($n = 25$) or 0.5 mg/kg prednisone daily ($n = 23$) until complete remission or a maximum of 8 weeks. The average time until improvement was 25.2 ± 13 days in the enoxaparin group compared with 9.7 ± 6 days in the oral prednisone group. In the enoxaparin group, 8 patients (32%) achieved complete remission, and 10 (40%) experienced partial improvement. In the oral prednisone group, 16 patients (69.6%) had complete remission, and 6 patients (26.1%) had partial improvement ($p < 0.05$). The mean lesion size after treatment was lower in the prednisone group ($p < 0.05$). The relapse rate was not significantly

different between the enoxaparin and prednisone groups (33% vs. 40.9%, respectively). No serious complications were found in the enoxaparin group, whereas 22% of the patients on prednisone experienced side effects, with the most common being dyspepsia.

Response of recalcitrant lichen planus to alitretinoin in 3 patients

Brehmer F, Haenssle HA, Schön MP, Emmert S. J Am Acad Dermatol 2011; 65: e58–60.

One patient with a 15-year history of cutaneous lichen planus and severe pruritus, a second patient with oral lichen planus, and a third patient with cutaneous and mucocutaneous lichen planus were treated with alitretinoin. The first patient was treated with 30 mg daily, and the other two patients were treated with 10 mg daily. All three patients responded dramatically to the alitretinoin within 4 weeks.

Alitretinoin is a retinoid that was developed for the treatment of hand eczema. There are several case reports of efficacy in the treatment of lichen planus, including two patients with nail lichen planus. As with other retinoids, elevation of serum lipids can occur.

An open-label pilot study of apremilast for the treatment of moderate to severe lichen planus: a case series

Paul J, Foss CE, Hirano SA, Cunningham TD, Pariser DM. J Am Acad Dermatol 2013; 68: 255-61.

Ten patients were treated with 20 mg apremilast twice daily for 12 weeks. After 12 weeks, 3 patients (30%) had at least a two-grade improvement in Physician Global Assessment, but all 10 patients had improvements in secondary end points such as lesion count. There was no loss of benefit when patients were assessed 28 days after the end of treatment. There were no serious adverse events.

Lichen sclerosus

Fiona M. Lewis

Lichen sclerosus (LS) is a chronic scarring dermatosis that has a predilection for the anogenital skin. It occurs in both sexes but is more common in females and has two peaks of incidence—in girls before puberty and in women after menopause. It can also affect the extragenital skin. It appears to be lymphocyte mediated, and there is a strong association with other autoimmune disorders and the presence of circulating antibodies in females but not in males. It is postulated that an inflammatory response to chronic exposure to urine in occluded skin may be an important etiologic factor in male genital

lichen sclerosis. A small number of patients with genital LS (<5%) will develop a squamous cell carcinoma (SCC).

Management Strategy

The aims of management are to alleviate symptoms, reduce scarring and hence maintain function, and, by careful follow-up, to detect any premalignant and malignant change.

The most common symptom of LS in females is pruritus, but soreness and pain can occur if the skin fissures. In children, constipation is often the presenting symptom. White atrophic plaques are the typical clinical feature, with ecchymosis being a frequent observation. Occasionally, the plaques may be thickened and hyperkeratotic. Perianal involvement occurs in a figure-of-eight pattern in females but is hardly ever seen in men. If untreated, scarring will lead to changes in the vulval architecture. The labia minora may be resorbed, and the clitoral hood can seal. Narrowing of the introitus can cause dyspareunia, and fusion of the labia minora may eventually lead to difficulties with micturition.

In males, tightening of the foreskin causes phimosis and subsequently problems with sexual function. Meatal stenosis leads to difficulties with micturition.

Secondary pain syndromes can develop in both sexes, and it is important to recognize these sensory disorders (vulvodynia, penile dysesthesia), as management must be directed to these rather than alter the treatment for LS. Any psychosexual issues must be recognized and addressed.

The first-line treatment for LS in adults and children of both sexes is an ultrapotent topical steroid. The general recommended regimen is clobetasol propionate 0.05% ointment once a day for a month, on alternate days for a month, and then twice weekly for a further month. After this 3-month period, the patient can apply treatment once daily if any symptoms occur. A 30-g tube should last at least 3 months in an adult and 6 months in a child, but the majority of patients use much less than this. With successful treatment, the ecchymosis, fissuring, and hyperkeratosis should resolve and scarring should not progress. The pallor will often remain and any scarring present before treatment starts will not reverse. There is no direct evidence that shows that treatment can reduce the risk of developing an SCC.

Soap substitutes (e.g., emulsifying ointment) are helpful symptomatically, and barrier preparations are recommended if there is urinary incontinence. Stool softeners can be helpful in children if constipation is an issue.

In women, surgery is only recommended for excision of any malignant lesion that develops or to release labial adhesions that are causing severe introital narrowing. However, in males circumcision may be a very helpful part of management.

Specific Investigations

- Biopsy
- Autoimmune screen if clinically indicated

A diagnosis of LS can often be made on the classic clinical appearances. Biopsy is mandatory if there are unusual or atypical features or in those who have failed to respond to first-line treatment.

Light microscopic criteria for the diagnosis of early vulvar lichen sclerosis: a comparison with lichen planus

Fung MA, LeBoit PE. Am J Surg Pathol 1998; 22: 473–8.

Nine out of 68 cases of LS reviewed were found to have sections that showed a transition from a lichenoid reaction to pathognomonic LS (dermal sclerosis or edema), thus demonstrating the early histopathologic signs of LS. A psoriasiform lichenoid pattern, basilar epidermotropism, loss of papillary dermal elastic fibers, basement membrane thickening, and epidermal atrophy were shown to be much more suggestive of LS than lichen planus.

Association of autoimmune diseases with lichen sclerosis in 532 male and female patients

Kreuter A, Kryvosheyeva Y, Terras S, Moritz R, Mollenhoff K, Altmeyer P, et al. Acta Derm Venereol 2013;93(2):238-41.

Concomitant autoimmune disease and circulating autoantibodies were found significantly more often in females than males with LS.

First-Line Therapies

• Ultrapotent topical steroids	A
• Emollients	E
• Use of soap substitutes	E

Topical interventions of genital lichen sclerosis

Chi CC, Kitschig G, Baldo M, Brackenbury F, Lewis F, Wojnarowska F. Cochrane Database Syst Rev 2011; 7: CD008240.

A Cochrane review, including seven randomly controlled trials with a total of 249 patients and investigating six treatments. This concluded that topical clobetasol propionate 0.05% and mometasone furoate were effective in treating LS, compared with placebo. No significant benefit was found for topical testosterone, dihydrotestosterone, and progesterone.

A double-blind, randomized prospective study evaluating topical clobetasol propionate 0.05% versus topical tacrolimus 0.1% in patients with vulvar lichen sclerosis

Funaro D, Lovett A, Leroux N, Powell J. J Am Acad Dermatol 2014; 71: 84–91.

In this randomized, double-blind controlled trial, 28 patients were treated with tacrolimus 1% ointment and 27 with clobetasol propionate 0.05% ointment once daily for 3 months. Signs and symptoms improved in both groups. However, clobetasol propionate was significantly more effective than tacrolimus.

The response of balanitis xerotica obliterans to local steroid application compared with placebo in children

Kiss A, Csontai A, Pirot L, Nyirady P, Merksz M, Kiraly L. Urol 2001; 165: 219–20.

A double-blind, placebo-controlled, randomized study of 40 boys comparing 0.05% mometasone furoate against placebo. The application of a potent topical steroid produced clinical improvement in phimosis in histologic early and intermediate disease and slowed deterioration in the late stages.

Treatment of vulval lichen sclerosis with topical corticosteroids in children: a study of 72 children

Casey G, Cooper S, Powell JJ. Clin Exp Dermatol 2015; 40: 289–92.

Sixty-two girls were treated prospectively with clobetasol propionate 0.05% ointment for 3 months. Ten others responded to a moderately potent steroid. 72.6% had complete resolution of symptoms compared with 32.2% of 31 patients who had used a moderately potent steroid.

First randomized trial of clobetasol propionate and mometasone furoate in the treatment of vulvar lichen sclerosis: results of efficacy and tolerability

Virgili A, Minghetti S, Corazza M, Borghi A. Brit J Dermatol 2014; 171: 388–96.

Fifty-four patients were randomized to apply clobetasol propionate 0.05% or mometasone furoate 0.1% on a tapering regimen for 12 weeks. Both showed equal efficacy with a response rate of 89% and were well tolerated.

Continuous versus tapering application of the potent topical corticosteroid mometasone furoate in the treatment of vulvar lichen sclerosis: results from a randomized trial

Borghi A, Corazza M, Minghetti S, Giulia T, Virgili A. Brit J Dermatol 2015; 173: 1381–6.

Sixty-four patients applied mometasone furoate 0.1% ointment on a reducing regimen over 12 weeks or continuously for 5 days per week. The response rate as reported by objective and subjective scores showed similar efficacy in both regimens.

This confirms that a tapering regimen is equally effective as continuous treatment.

Does treatment of vulvar lichen sclerosis influence its prognosis?

Cooper S, Gao X-H, Powell JJ, Wojnarowska F. Arch Dermatol 2004; 140: 702–6.

A study of 327 females (74 children and 253 adults) with response to treatment recorded in 255 patients at least 3 months after the start of topical application. Symptoms improved in 96% of those treated with an ultrapotent topical steroid. Clinical signs were recorded in 253 patients; 23% showed a complete response with return of normal

texture and color, 68% had a partial response, and 7% a poor response.

Second-Line Therapies

• Circumcision	B
• Topical tacrolimus	B
• Topical pimecrolimus	A

Lichen sclerosus of the male genitalia and urethra: surgical options and results in a multicenter international experience of 215 patients

Kulkarni S, Barbagli G, Kirpekar D, Mirri F, Lazzeri M. Eur Urol 2009; 55: 945–54.

A large retrospective observational study comparing circumcision and/or meatotomy, one- or two-stage penile oral mucosal graft urethroplasty, and definitive perineal urethrostomy. Circumcision alone or together with meatotomy was successful in 100% of cases, meatotomy alone in 80%, and various forms of urethroplasty in 73% to 91%.

It is not stated whether any of these patients who required surgery for persistent phimosis had received any topical treatment first.

Multicenter, phase II trial on the safety and efficacy of topical tacrolimus ointment for the treatment of lichen sclerosus

Hengge UR, Krause W, Hofmann H, Stadler R, Gross G, Meurer M, et al. Br J Dermatol 2006; 155: 1021–8.

A prospective study of 84 patients (49 women, 32 men, and 3 girls) treated with 0.1% topical tacrolimus ointment twice daily for up to 24 weeks. Thirty-six percent had a complete, and 29% a partial, clinical response.

Topical calcineurin inhibitors decrease immune surveillance and can

reactivate infection. There are therefore major concerns about using them in a disease such as LS where malignancy can develop.

A double-blind, randomized controlled trial of clobetasol versus pimecrolimus in patients with vulvar lichen sclerosis

Goldstein AT, Creasey A, Pfau R, Phillips D, Burrows LJ. J Am Acad Dermatol 2011; 64: 99e–104e.

A group of 38 women were treated for 12 weeks. Clobetasol propionate 0.05% was superior in improving inflammation as seen in posttreatment biopsies. Both treatments showed improvement in symptoms and a decreased clinical evaluation score.

Third-Line Therapies

• Acitretin	A
• CO ₂ laser	B

Acitretin for severe lichen sclerosis of male genitalia: a randomized, placebo controlled study

Ioannides D, Lazaridou E, Apalla Z, Sotiriou E, Gregoriou S, Rigopoulos D. J Urol 2010; 183: 1395–9.

Men ($n = 52$) with severe long-standing LS were treated with acitretin 35 mg/day or placebo for 20 weeks. A complete response was achieved in 36.4% vs. 6.3% of controls.

The double-blind nature of this study is limited because of the expected side effects of oral acitretin as opposed to placebo.

Is carbon dioxide laser treatment of lichen sclerosis effective in the long run?

Windahl T. Scand J Urol Nephrol 2006; 40: 208–11.

A retrospective review of 62 men who had failed to respond adequately to a topical steroid, although the potency is not specified. They were treated with CO₂ laser (15–20 W output with defocused beam) with vaporization of macroscopically abnormal areas on the glans penis. Of 50 patients who were contacted up to 14 years after treatment, 80% had no symptoms or visible lesion. Two men were found to have SCC at follow-up.

Other Therapies

• Photodynamic therapy with 5-aminolevulinic acid	B
• Topical calcipotriol	B
• Topical tretinoin	B
• Oxatomide gel	B
• Topical testosterone	B
• Oral stanozolol	B
• Low-dose ultraviolet A1 phototherapy	C
• Antibiotics	D
• Intralesional triamcinolone	D
• Surgery for clitoral phimosis	D
• Cryosurgery	D
• Ciclosporin	D
• Potassium <i>p</i> -aminobenzoate	D
• Adipose-derived mesenchymal cells and platelet-rich plasma	D
• Focused ultrasound therapy	D
• Hydroxycarbamide	E
• Hydroxyurea	E
• Methotrexate	E
• Oral calcitriol	E
• Extracorporeal photopheresis	E

Low-dose ultraviolet A1 phototherapy for extragenital lichen sclerosis: results of a preliminary study

Kreuter A, Gambichler T, Avermaete A, Happe M, Bacharach-Buhles M, Hoffmann K, et al. J Am Acad Dermatol 2002; 46: 251–5.

A series of 10 patients (8 female and 2 male) were treated with low-dose (ultraviolet A1) four times a week for 10 weeks with a cumulative UVA1 dose of 800 J/cm². A marked reduction in clinical score, decrease in skin thickness, and increase in dermal density was seen in all patients who also reported a subjective improvement.

UVA1 phototherapy for genital lichen sclerosis

Beattie PE, Dawe RS, Ferguson J, Ibbotson SH. Clin Exp Dermatol 2006; 31: 343–7.

Five out of seven patients had moderate (three patients) or minimal (two patients) improvement after at least 15 treatments with UVA1 three to five times weekly.

The extragenital lesions of LS appear to respond better to UVA1. There are also concerns about an increased potential for the development of SCC with phototherapy.

Open-label trial of ciclosporin for vulvar lichen sclerosis

Bulbul Baskan E, Turan H, Tunalı S, Cikman Toker S, Saricaoglu H. J Am Acad Dermatol 2007; 57: 276–8.

A retrospective study of five women with recalcitrant LS unresponsive to several topical treatments treated with ciclosporin 3 to 4 mg/kg/day for 3 months. An improvement in symptoms was seen in all patients. There was no relapse on discontinuation of the drug, and in the 12-month follow-up any recurrent symptoms were controlled with clobetasol dipropionate cream.

Again, there is a potentially increased risk of SCC with the use of immunosuppressants in LS.

Efficacy of photodynamic therapy in vulvar lichen sclerosis treatment based on immunohistochemical analysis of CD34, CD44, myeline basic protein and Ki67 antibodies

Olejek A, Steplewska K, Gabriel A, Kozak-Darmas I, Jarek A, Kellas-Slecza S, et al. Int J Gynecol Cancer 2010; 20: 879–87.

One hundred women were treated with photodynamic therapy with improvement in signs and symptoms.

Treatment of lichen sclerosus with antibiotics

Shelley WB, Shelley ED, Amurao CV. Int J Dermatol 2006; 45: 1104–6.

A retrospective review of 15 patients (9 females and 4 males) treated with oral or intramuscular penicillin or cephalosporin for 3 to 21 months. Four patients cleared completely, and the rest reported an improvement in symptoms.

The rationale for using antibiotic therapy was based on the debatable evidence for an infectious etiology for LS, in particular, the possibility of Borrelia burgdorferi as a causative agent.

Lichen simplex chronicus

Michael Renzi, Lacy L. Sommer, and Donald J. Baker

Lichen simplex chronicus (LSC, or neurodermatitis circumscripta) is characterized by pruritic, lichenified plaques that most often occur

on the neck, anterior tibias, ankles, wrists, and anogenital region in response to chronic localized scratching or rubbing. Primary LSC evolves on apparently normal skin from pruritus of unclear etiology, whereas secondary LSC is superimposed upon preexisting dermatoses, especially atopic dermatitis, psoriasis, or dermatophytosis.

Psychogenic factors can play an important contributory role, and psychopathology, such as anxiety and obsessive-compulsive disorder, has been found at higher rates in LSC groups compared with control groups. Neurologic abnormalities may sometimes be a factor in the etiology of LSC, as an association between long-standing LSC on the limbs and chronic cervical or lumbar radiculopathy has been reported.

Management Strategy

The objective of treatment is to remove environmental triggers, break the itch–scratch cycle, and treat any underlying cutaneous or systemic disease. Patients' understanding of their role in the itch–scratch cycle is essential if their cooperation in avoiding scratching is to be enlisted, thereby facilitating a more complete and permanent recovery.

Recurrences are frequent, and complete resolution often requires multiple approaches to therapy. Environmental triggers such as harsh skin care products or bathing regimens, friction, and excessive moisture or dryness should be minimized or eliminated. High-potency *topical corticosteroids*, such as clobetasol, diflorasone, and betamethasone, as creams or ointments, are the initial treatments of choice. The potency and/or frequency of application of topical corticosteroids should be decreased as the lesion resolves to avoid atrophy with their long-term use. Adjunctive therapies such as *doxepin cream* may be introduced if topical corticosteroids are not easily tapered. Occlusion has been found to be a successful aid to therapy because it provides a physical barrier to prevent scratching and permits enhanced and prolonged application of topical medications. *Occlusive plastic film* or hydrocolloid dressings have been used alone or over mid-potency corticosteroids. *Flurandrenolide tape* is very effective as both an occlusive and antiinflammatory measure and is usually changed once daily, although a short occlusion-free period each day will help minimize the side effects of occlusion therapy. In chronic, difficult cases on the lower leg, an Unna boot (a gauze roll

impregnated with zinc oxide) may be applied for up to 1 week, provided there is no concomitant infection of the occluded area. *Calcineurin inhibitors* such as *tacrolimus* and *pimecrolimus* also have been successfully used as monotherapy to treat LSC and offer a good alternative for treatment in steroid-sensitive areas such as the genitalia.

Intralesional injections of triamcinolone at monthly intervals can rapidly induce involution. Although highly effective, repeated injections may cause depigmentation or thinning of the epidermis; therefore other therapies should be used if several treatments with intralesional corticosteroids do not clear LSC. Infected areas should not be injected with corticosteroids because of the risk of abscess formation. Secondary infections should be treated with appropriate topical or systemic antibiotics. Intralesional *botulinum toxin* has been reported to offer lasting relief in patients with recalcitrant LSC.

A variety of other therapies have been reported to be effective in the management of LSC. *Doxepin cream*, *capsaicin cream*, and *aspirin/dichloromethane solution* are occasionally of value as monotherapy but are probably best used as adjunctive therapy when LSC does not quickly clear with topical or intralesional corticosteroids. *Oral antihistamines* may be useful for their sedative effect on patients who scratch during their sleep. *Surgical excision* has been used infrequently to treat nodular LSC. Noninvasive *transcutaneous electrical nerve stimulation (TENS)* has emerged as a possible effective treatment for pruritic dermatoses such as LSC. Pruritus and neuralgia of varying etiologies have responded to the anticonvulsant *gabapentin*, which may explain its usefulness in treating LSC. In more severe or recalcitrant conditions, *psychotherapy* and/or the use of *psychopharmacologic agents* may be needed for sustained improvement. *Benzodiazepines*, *amitriptyline*, *pimozide*, and *doxepin* have been used to treat neurotic excoriations and severe neurodermatitis. Neurodermatitis has improved with habit-reversal *behavioral therapy*, *biofeedback*, and *hypnotherapy* in certain individuals. *Acupuncture* and *electroacupuncture* are labor intensive but have been effective in treating some cases of LSC. *Alitretinoin* was used successfully in a single case of LSC on the hands. Adjuvant therapy with *narrowband ultraviolet B (UVB) phototherapy* and *silk fabrics* may prove useful for cases of vulvar LSC.

Specific Investigation

- Skin biopsy with periodic acid–Schiff stain

LSC that is atypical in appearance or poorly responsive to therapy should be biopsied and cultured to look for preexisting dermatoses and underlying cutaneous malignancy or infection. Squamous cell carcinoma, though rare, has been reported to develop within long-standing LSC. Lesions should be surveyed carefully, and fixed plaques or proliferating nodules should raise suspicion for malignant transformation.

First-Line Therapies

• Topical corticosteroids	A
• Occlusion – flurandrenolide tape	C
• Intralesional corticosteroids	C

A double-blind, multicenter trial of 0.05% halobetasol propionate ointment and 0.05% clobetasol 17-propionate ointment in the treatment of patients with chronic, localized atopic dermatitis or lichen simplex chronicus

Datz B, Yawalkar S. J Am Acad Dermatol 1991; 25: 1157–60.

In 127 patients with chronic, localized atopic dermatitis or LSC, healing was reported in 65.1% of those treated with halobetasol propionate ointment (a superpotent group I topical corticosteroid) compared with 54.7% of those treated with clobetasol propionate (a weaker group I topical corticosteroid). Success rates, early onset of therapeutic effect, and adverse effects were similar in the two treatment groups.

Group I topical corticosteroids should not be used for more than 2 weeks. They are therefore best combined with adjuvant therapies such as topical doxepin or pimecrolimus cream.

Flurandrenolone tape in the treatment of lichen simplex chronicus

Bard JW. J Ky Med Assoc 1969; 67: 668–70.

Of the 18 patients in the study, 10 used flurandrenolone tape, and 8 used a topical corticosteroid preparation without occlusion. Lasting remissions were seen in 70% of those using the tape versus 25% of those using topical corticosteroids without occlusion. Duration of therapy is not mentioned.

The use of occlusion with topical corticosteroids is considered the treatment of choice for LSC despite the lack of adequate clinical trials.

Update on intralesional steroid: focus on dermatoses

Richards RN. J Cutan Med Surg 2010; 14: 19–23.

In the absence of any formal clinical studies since the 1960s, Richards compiled a review of peer-reviewed literature, six standard dermatology textbooks, and questionnaires from dermatologists to summarize the available information on the use of intralesional steroids in localized dermatoses. Pooled clinical experience is presented in this review, which suggests that triamcinolone acetonide 2.5 mg/mL administered in total doses of 7.5 to 20 mg intralesionally every 3 to 4 weeks has proven to be a safe, economical, and highly effective treatment for localized dermatoses such as LSC.

Corticosteroid injections are considered first-line therapy despite the lack of adequate controlled clinical trials.

Second-Line Therapies

• Doxepin cream	B
• Pimecrolimus cream	C
• Tacrolimus ointment	B
• Capsaicin cream	E

The antipruritic effect of 5% doxepin cream in patients with eczematous dermatitis. Doxepin Study Group

Drake LA, Millikan LE. Arch Dermatol 1995; 131: 1403–8.

A multicenter, double-blind trial conducted to evaluate the safety and antipruritic efficacy of 5% doxepin cream in patients with LSC ($n = 136$), nummular eczema ($n = 87$), or contact dermatitis ($n = 86$). Patients treated with doxepin versus vehicle had significantly greater pruritus relief. Of doxepin-treated patients, 60% experienced relief from pruritus within 24 hours with a response rate of 84% by the end of the study.

Pimecrolimus 1% cream for pruritus in postmenopausal diabetic women with vulvar lichen simplex chronicus: a prospective noncontrolled case series

Kelekci HK, Uncu HG, Yilmaz B, Ozdemir O, Sut N, Kelekci S. J Dermatolog Treat 2008; 19: 274–8.

Twelve postmenopausal diabetic women with vulvar LSC were treated with pimecrolimus 1% cream twice daily for 3 months. All patients experienced a statistically significant reduction in pruritus when evaluated at 4 weeks and 12 weeks. After 3 months of treatment, 10 women (83.3%) had a complete cure, and the pruritus was improved in the 2 remaining women.

Effective treatment of scrotal lichen simplex chronicus with 0.1% tacrolimus ointment: an observational study

Tan ES, Tan AS, Tey HL. J Eur Acad Dermatol Venereol 2015; 29: 1448–9.

In this prospective, observational study, 29 men presenting with scrotal LSC were treated with 0.1% tacrolimus ointment twice daily for 6 weeks. After treatment, there were statistically significant improvements ($p \leq 0.001$) in mean itch score, mean itch frequency, mean sleep score, degree of skin modification, and mean affected scrotal surface area. The mean onset of action was 3.5 days. Six patients experienced intolerable burning sensation and discontinued treatment.

Treatment of prurigo nodularis, chronic prurigo and neurodermatitis circumscripta with topical capsaicin

Tupker RA, Coenraads PJ, van der Meer JB. Acta Derm Venereol 1992; 72: 463.

In this small, open study, two patients with corticosteroid-unresponsive neurodermatitis circumscripta were treated with 0.25% capsaicin, applied five times daily, resulting in flatter lesions and marked relief of itching.

Third-Line Therapies

• Transcutaneous electrical stimulation	B
• Acupuncture and electroacupuncture	C
• Botulinum toxin	D
• Aspirin	A
• Gabapentin	D
• Psychotherapy	E
• Hypnosis	E
• Psychopharmacotherapy	E
• Surgical excision	E
• Alitretinoin	E
• Phototherapy	E
• Silk underwear	A

Use of transcutaneous electrical nerve stimulation for chronic pruritus

Mohammad Ali BM, Hegab DS, El Saadany HM. Dermatol Ther 2015:

28: 210–5.

Ten patients with atopic dermatitis (group I), 20 patients with LSC (group II), and 16 with chronic intractable pruritus from chronic liver disease (group III) had their most pruritic, distressing lesions treated with TENS. Treatment occurred during three 30-minute sessions each week and continued for a maximum of 12 sessions or until symptomatic resolution was obtained. The results showed statistically significant mean reductions in visual analog scale (VAS) scores at weeks 2 and 4 compared with baseline for all groups. At the 1-month follow-up mean reductions in visual analog itch scores from baseline remained statistically significant for groups I and II but were found to be statistically insignificant for group III.

Acupuncture treatment of 139 cases of neurodermatitis

Yang Q. J Tradit Chin Med 1997; 17: 57–8.

Acupuncture was used to treat 96 patients with localized neurodermatitis and 43 patients with generalized neurodermatitis. A course of treatment was 10 days, with 3- to 5-day rest periods between multiple courses of therapy. An 81% cure rate and 14% improvement rate were reported, but the number of courses of therapy and long-term follow-up were not specified.

Acupuncture and electroacupuncture (where acupuncture needles are stimulated with low-voltage, high-frequency stimulation) may be used to reduce the proinflammatory neuropeptide state in pruritic and inflamed skin and thereby promote a more normal state of neuropeptide homeostasis.

Botulinum toxin type A injection in the treatment of lichen simplex: an open pilot study

Heckmann M, Heyer G, Brunner B, Plewig G. J Am Acad Dermatol 2002; 46: 617–9.

Four patients received 20 units of botulinum toxin type A (100 U/mL) per 2 cm × 2 cm area of an LSC plaque. One week after injection, there was a noticeable reduction in pruritus. Three patients were free of itching, and the remaining patient had >50% reduction in itching. After 12 weeks, three patients remained asymptomatic.

The effect of topically applied aspirin on localized circumscribed neurodermatosis

Yosipovitch G, Sugeng M, Chan YH, Goon A, Ngim S, Goh CL. J Am Acad Dermatol 2001; 45: 910–3.

In this double-blind, crossover, placebo-controlled study, 29 patients with LSC were randomized to receive aspirin/dichloromethane solution treatment followed by placebo or vice versa. In the aspirin/dichloromethane treatment group 46% achieved a significant response, and 12% of the placebo group achieved a comparable improvement.

Therapeutic hotline: treatment of prurigo nodularis and lichen simplex chronicus with gabapentin

Gencoglan G, Inanir I, Gunduz K. *Dermatol Ther* 2010; 23: 194–8.

Five patients with LSC and four with prurigo nodularis refractory to antihistamines, corticosteroids, phototherapy, and antidepressants were treated with gabapentin. Gabapentin therapy was initiated at 300 mg/day and titrated up by 300 mg/day every 3 days to a final dose of 900 mg/day. Doses were subsequently decreased during a total treatment period ranging from 4 to 10 months. After 2 months, some reduction in pruritus was noted in all patients. Clinical improvement was maintained during the 3-month follow-up period after patients discontinued gabapentin. All patients had improvement in their pruritus, with residual itching responding to topical lubricants. Side effects were limited to tolerable sedation in some patients.

The behavioral treatment of neurodermatitis through habit-reversal

Rosenbaum MS, Ayllon T. *Behav Res Ther* 1981; 19: 313–8.

Four patients with neurodermatitis received a single treatment session in which they learned to substitute a competing response for their urges to scratch. There was a rapid reduction in scratching in all patients. At 6 months, scratching had been eliminated in one patient and markedly reduced in three patients.

Brief hypnotherapy of neurodermatitis: a case with 4-year followup

Lehman RE. *Am J Clin Hypn* 1978; 21: 48–51.

One patient with extensive neurodermatitis was treated with eight sessions of hypnotherapy. She was clear within 2 weeks after her last session and remained clear at 4-year follow-up.

Improvement of chronic neurotic excoriations with oral doxepin

therapy

Harris BA, Sherertz EF, Flowers FP. *Int J Dermatol* 1987; 26: 541–3.

Two patients with chronic neurotic excoriations had improvement in symptoms and in clinical signs of their skin condition within several weeks of receiving oral doxepin (30–75 mg daily).

Nodular lichen simplex of the scrotum treated by surgical excision

Porter WM, Bewley A, Dinneen M, Walker CC, Fallowfield M, Francis N, et al. *Br J Dermatol* 2001; 144: 343–6.

Two patients with nodular LSC of the scrotum were treated by surgical excision of LSC plaques with remission lasting over 12 months.

Efficacy of treatment with oral alitretinoin in patient suffering from lichen simplex chronicus and severe atopic dermatitis of hands

D’Erme AM, Milanesi, N, Angoletti AF, Maio V, Massi D, Gola M. *Dermatol Ther* 2014; 27: 21–3.

One patient with LSC of the hands and underlying atopic dermatitis received alitretinoin 30 mg daily and topical emollients for 12 weeks. Substantial clinical improvement was achieved with no recurrence observed 4 months after the end of treatment.

Phototherapy for vulvar lichen simplex chronicus: an “off-label use” of comb light device

Virgili A, Minghetti S, Borghi A, Corazza M. *Photodermatol Photoimmunol Photomed* 2014; 30: 332–4.

One patient with vulvar LSC received narrowband UVB phototherapy with a 211-nm comblike instrument marketed for scalp dermatitis. Treatment was performed three times per week for 14 weeks with dose titration up to 980 mJ/cm². Clinical characteristics and symptoms began to improve after 4 weeks. Marked improvement was reported at 10 weeks with complete resolution at 14 weeks.

Effectiveness of silk fabric underwear as an adjuvant tool in the management of vulvar lichen simplex chronicus: results of a double-blind randomized controlled trial

Corazza M, Borghi A, Minghetti S, Toni G, Virgili A. *Menopause* 2015; 22:850-6.

In this double-blind study 20 women with vulvar LSC were entered into a 1-week, open-label, active treatment phase in which they applied 0.1% mometasone furoate (MMF) ointment once daily to the affected vulva. Participants entered a 4-week maintenance phase in which they were randomly assigned to wear either silk or cotton briefs. At the end of the maintenance phase, the silk group was shown to have fewer MMF applications, an increased mean symptom-free interval, and greater improvement in symptom severity compared with the cotton group.

Linear IgA bullous dermatosis

Neil J. Korman

Linear IgA bullous dermatosis is an acquired autoimmune blistering disease of the skin and mucous membranes. The skin lesions consist of papulovesicles or blisters that may have an arcuate pattern, with a “cluster of jewels” grouping of blisters along with urticarial plaques. Involvement of the oral mucous membranes is common, and ocular involvement, with subsequent scarring of the conjunctiva, may uncommonly occur. Although originally believed to be a distinct entity, it is now clear that chronic bullous disease of

childhood is the childhood counterpart of adult linear IgA bullous dermatosis. Direct immunofluorescence studies demonstrate that all patients have linear IgA deposits at the epidermal basement membrane zone, and the diagnosis of linear IgA bullous dermatosis is dependent on this finding. The target antigens involved are 97 kDa and, less commonly, 290 kDa. The 97-kDa antigen is an anchoring filament protein that is part of the 180-kDa bullous pemphigoid antigen-2, and antibodies directed against the 290-kDa protein represent an IgA response directed against type VII collagen. Several reports stress the association with ulcerative colitis. Drug-induced disease is a well-recognized entity, and vancomycin is the most commonly implicated agent.

Management Strategy

If drug-induced disease is considered, the suspect trigger drug must be withdrawn. Treatment of linear IgA bullous dermatosis is dictated by the severity of disease and the areas of involvement. All patients should be evaluated by an ophthalmologist to ensure the absence of ocular disease. Because linear IgA bullous dermatosis tends to be chronic, it is important to be aware of the potential not only for short-term, but also for long-term, toxicities in any treatment used. In addition, treatment of children with chronic bullous disease of childhood (the childhood counterpart of linear IgA bullous dermatosis of adults) requires special consideration to ensure that any medications used have no specific contraindications in children.

The majority of patients with disease limited to the skin will respond well to treatment with *dapsone*, and this is the first-line therapy for patients with linear IgA bullous dermatosis. Dapsone generally works quite rapidly, with responses often occurring in the first few days of starting the drug. It is most effective for the skin lesions of linear IgA bullous dermatosis, with the mucous membrane lesions being more resistant.

The dosage of dapsone for patients with linear IgA bullous disease should be individually titrated to determine the best dose that effectively controls the disease. Typically, initial dosages in adults range from 50 to 100 mg/day. If sufficient control is not achieved after 6 to 8 weeks, a higher dosage may be tried (as high as 150–200 mg/day), typically increasing the dose by 25 mg per month while monitoring laboratory studies. After disease control is attained, the

dosage can then be slowly reduced to the minimum that maintains appropriate control.

Because of a dose-related oxidant stress on normal aging red blood cells, all patients treated with dapsone will experience some degree of hemolysis that is usually dose dependent. A reduction of approximately 2 to 3 g of hemoglobin is often observed. As long as this decrease is relatively gradual and patients have no history of cardiovascular disease or anemia, this is usually well tolerated. It is important to measure levels of glucose-6-phosphate dehydrogenase (G6PD) in patients to be treated with dapsone because those with a deficiency in this enzyme can develop severe hemolysis.

Methemoglobinemia, which is also dosage dependent, occurs in most patients but is usually asymptomatic. More worrisome toxicities include bone marrow suppression and even agranulocytosis, which usually occurs early in the course of therapy, and a dapsone-induced neuropathy, which occurs more commonly in patients treated for several years with more than 200 mg of dapsone daily. Less commonly, hepatitis, nephritis, pneumonitis, erythema multiforme, and the dapsone hypersensitivity syndrome have all been reported.

For those patients who fail to achieve satisfactory control of their disease with dapsone as first-line therapy, it is often of value to add *systemic corticosteroids*. This combination is considered second-line therapy. The dosage of prednisone required is often in the 20-to 40-mg daily range. Often the addition of prednisone will not only cause significant clinical improvement, but it may also allow the dosage of dapsone to be reduced, thereby minimizing its potential toxicity.

Other viable second-line therapies include *colchicine*, *sulfapyridine*, and the combination of *doxycycline* or *minocycline* and *niacinamide plus sulfapyridine* at doses of approximately 1 to 3 g daily, and colchicine has been reported to be beneficial at doses of 1.0 to 1.5 mg daily. The combination of doxycycline or minocycline and niacinamide, usually at doses of 1.5 g of niacinamide and 200 mg of doxycycline or minocycline, has been used with success. Doxycycline and minocycline should not be used in children under 9 years of age because they can both permanently stain teeth.

Third-line therapies include sulfamethoxypyridazine, dicloxacillin, erythromycin, mycophenolate mofetil, azathioprine, ciclosporin, methotrexate, interferon- α , and intravenous immunoglobulin (IVIG). Toxicity profiles and financial considerations favor using erythromycin, dicloxacillin, or sulfamethoxypyridazine before

treatment with the immunosuppressive agents or IVIG. Although there is a role for the use of rituximab in the treatment of most of the other autoimmune blistering diseases, there is a question as to whether rituximab is of value in the treatment of linear IgA bullous dermatosis.

Specific Investigations

- Skin biopsy of blister for histology
- Perilesional skin biopsy for direct immunofluorescence
- Indirect immunofluorescence
- Consider G6PD level before dapsone use
- Consider thiopurine methyl transferase estimation before azathioprine use
- Ophthalmology consult

Linear IgA disease in adults

Linear immunoglobulin A bullous dermatosis

Fortuna G, Marinkovich MP. Clin Dermatol 2012; 30: 38–50.

These are excellent reviews of the clinical and immunologic features of

linear IgA bullous dermatosis.

Vancomycin-induced linear IgA bullous dermatosis

Baden LA, Apovian C, Imber MJ, Dover JS. Arch Dermatol 1988; 124: 1186–8.

Litt's Drug Eruption Reference Manual, 10th ed. (Taylor & Francis, New York, 2004) implicates acetaminophen, aldesleukin, amiodarone, ampicillin, atorvastatin, candesartan, captopril, carbamazepine, cefamandole, ceftriaxone, cotrimoxazole, ciclosporin, diclofenac, furosemide, glyburide, granulocyte–macrophage colony-stimulating factor, ibuprofen, interferon- α , lithium, metronidazole, naproxen, penicillins, phenytoin, piroxicam, rifampin, sulfamethoxazole, and vancomycin as drug triggers for linear IgA disease. The extent of disease may sometimes simulate toxic epidermal necrolysis.

The diagnosis of linear IgA bullous dermatosis requires routine histologic studies as well as direct and indirect immunofluorescence studies. Once the diagnosis is confirmed, laboratory studies to be obtained will depend on the specific treatment anticipated.

First-Line Therapy

• Dapsone

C

Linear IgA dapsone responsive bullous dermatosis

Wojnarowska F. J Roy Soc Med 1980; 73: 371–3.

One of the first reports of this condition and response to dapsone. Since then, most series have demonstrated dapsone to be the most effective first-line monotherapy.

Second-Line Therapies

• Dapsone and prednisone	D
• Sulfapyridine	C
• Colchicine	D
• Tetracycline and niacinamide	E

Colchicine as a novel therapeutic agent in chronic bullous dermatosis of childhood

Banodkar DD, Al-Suwaid AR. Int J Dermatol 1997; 36: 213–6.

Eight patients were given colchicine, five of whom showed complete remission within 4 to 6 weeks. The remaining three also responded but required concurrent steroids to maintain remission.

Treatment of pemphigus and linear IgA dermatosis with nicotinamide and tetracycline

Chaffins ML, Collison D, Fivenson DP. J Am Acad Dermatol 1993; 28: 998–1001.

Sublamina densa-type linear IgA bullous dermatosis successfully treated with oral tetracycline and niacinamide

Yomoda M, Komani A, Hashimoto T. Br J Dermatol 1999; 141: 608–9.

There are four reports of successful use of 2 g of tetracycline and 1.5 g of nicotinamide daily in adults only.

Third-Line Therapies

• Sulfamethoxypyridazine	E
• Dicloxacillin	E
• Flucloxacillin	E
• Erythromycin	E
• Trimethoprim–sulfamethoxazole	E
• Methotrexate	E
• Interferon- α	E
• Mycophenolate mofetil	E
• Azathioprine	E
• Ciclosporin	E
• IVIG	E
• Thalidomide	E
• Immunoabsorption	E

Sulphamethoxypridazine for dermatitis herpetiformis, linear IgA disease, and cicatricial pemphigoid

McFadden JP, Leonard JN, Powles AV, Rutman AJ, Fry L. Br J Dermatol 1989; 121: 759–62.

Reports of sulfamethoxypyridazine (0.25–1.5 g daily) use as monotherapy in four patients with linear IgA disease who were intolerant of dapsone.

Treatment of chronic bullous dermatosis of childhood with oral

dicloxacillin

Skinner RB, Totondo CK, Schneider MA, Raby L, Rosenberg EW. *Pediatr Dermatol* 1995; 12: 65–6.

Chronic bullous disease of childhood: successful treatment with dicloxacillin

Siegfried EC, Sirawan S. *J Am Acad Dermatol* 1998; 39: 797–800.

Mixed immunobullous disease of childhood: a good response to antimicrobials

Powell J, Kirtschig G, Allen J, Dean D, Wojnarowska F. *Br J Dermatol* 2001; 144: 769–74.

Linear IgA bullous dermatosis responsive to trimethoprim-sulfamethoxazole

Peterson JD, Chan LS. *Clin Exp Dermatol* 2007; 32: 756–8.

Linear IgA disease: successful treatment with erythromycin

Cooper SM, Powell J, Wojnarowska F. *Clin Exp Dermatol* 2002; 27: 677–9.

Treatment of linear IgA bullous dermatosis of childhood with flucloxacillin

Alajlan A, Al-Khawajah M, Al-Sheikh O, Al-Saif F, Al-Rasheed S, Al-Hoqail I, et al. *J Am Acad Dermatol* 2006; 54: 652–6.

Antibiotics have been used largely in childhood disease and are a reasonable option because of their low toxicity.

Treatment of linear IgA bullous dermatosis of childhood with mycophenolate mofetil

Farley-Li J, Mancini AJ. *Arch Dermatol* 2003; 139: 1121–4.

Successful treatment of oral linear IgA disease using mycophenolate

Lewis MA, Yaqoob NA, Emanuel C, Potts AJ. *Oral Surg Oral Med Oral Pathol Oral Radiol Endod* 2007; 103: 483–6.

The adult dose is usually 35 to 45 mg/kg, which is about 1.5 g twice daily for a 75-kg adult.

Methotrexate and cyclosporine are of value in the treatment of

adult linear IgA disease

Burrows NP, Jones RR. J Dermatol Treat 1992; 3: 31–3.

Linear IgA disease: successful treatment with cyclosporine

Young HS, Coulson IH. Br J Dermatol 2000; 143: 204–5.

Therapy-resistant blistering responding to ciclosporin 4 mg/kg daily.

Interferon alpha for linear IgA bullous dermatosis

Chan LS, Cooper KD. Lancet 1992; 340: 425.

High-dose intravenous immune globulin is also effective in linear IgA disease

Kroiss MM, Vogtt T, Landthaler M, Stolz W. Br J Dermatol 2000; 142: 582–4.

Successful treatment of linear IgA disease with salazosulphapyridine and intravenous immunoglobulins

Goebeler M, Seitz C, Rose C, Sitaru C, Jeschke R, Marx A, et al. Br J Dermatol 2003; 149: 912–4.

Upper aerodigestive tract complications in a neonate with linear IgA bullous dermatosis

Gluth MB, Witman PM, Thompson DM. Int J Pediatr Otorhinolaryngol 2004; 68: 965–70.

A newborn with skin involvement had life-threatening respiratory compromise from disease affecting the larynx, subglottis, trachea, and esophagus. Management with both tracheostomy and gastrostomy tube placement was necessary. Treatment included systemic corticosteroids, dapsone, and IVIG.

High-dose intravenous immunoglobulins for the treatment of autoimmune mucocutaneous blistering diseases: evaluation of its use in 19 cases

Segura S, Iranzo P, Martínez-de Pablo I, Mascaró JM Jr, Alsina M, Herrero J, et al. J Am Acad Dermatol 2007; 56: 960–7.

As the use of IVIG therapy for autoimmune blistering diseases has evolved, it has become clear that to obtain optimal results, patients should receive treatment with high-dose IVIG, defined as 2 g/kg per

cycle, typically given at 4-week intervals.

Linear IgA bullous dermatosis of childhood: response to thalidomide

Madnani NA, Khan KJ. Indian J Dermatol Venereol Leprol 2010; 76: 427–9.

An 8-year-old boy demonstrated a dramatic response with thalidomide with total clearance in 1 month, and while on treatment he was disease free for 1 year. The authors postulate that thalidomide works by inhibition of interleukin-12, which is a potent proinflammatory cytokine. Development of neuropathy is a concern with long-term use.

Linear IgA disease: successful application of immunoadsorption and review of the literature

Kasperkiewicz M, Meier M, Zillikens D, Schmidt E. Dermatology 2010; 220: 259–63.

Immunoadsorption has been previously successfully applied in severe and/or otherwise treatment-resistant IgG-mediated immunobullous disorders.

Lipodermatosclerosis

Cecilia A. Larocca, and Tania J. Phillips

Lipodermatosclerosis (LDS) is the result of a progressive fibrotic process of the skin and subcutaneous fat induced by chronic venous insufficiency. It usually presents as a sclerotic region, often surrounding venous ulcers, above the medial malleolus on the lower leg. The diagnosis is based on clinical findings. LDS more often affects middle-aged to elderly obese women with venous abnormalities. Pain is the most consistent presenting symptom. Two stages of LDS have

been described: acute and chronic. The acute form presents with painful, tender, and slightly indurated plaques. Often, clinicians mistake the acute form for cellulitis, phlebitis, erythema nodosum, inflammatory morphea, or panniculitis. The chronic variant, which is strongly associated with venous insufficiency, is densely indurated and less painful than the acute form. It may be associated with hyperpigmentation. In its late stages, chronic LDS alters the shape of the leg, making it look like an inverted bottle, with extreme fibrosis and sclerosis in the dermis and subcutaneous tissue. Acute or chronic presentations may also occur.

Management Strategy

The current treatment of choice is the *combination of stanozolol and compression therapy*. However, patients with acute LDS often find compression therapy painful. In this case stanozolol is used alone. Stanozolol is contraindicated in patients with uncontrolled hypertension and heart failure. Of note, although stanozolol is no longer commercially available in the United States, danazol has been used as an alternative. However, stanozolol is still available in Europe, and its purchase is unregulated online. *Pentoxifylline* is an alternative that stimulates fibrinolysis but may cause gastrointestinal upset. *Niacin* has some fibrinolytic properties and has also been used. Other treatments, such as *antibiotics, antiinflammatory agents, antimetabolites, and long-term cimetidine*, have also been proposed. Intralesional triamcinolone, platelet-rich plasma, and topical capsaicin may be helpful. *Surgical approaches include subfascial perforator endoscopic surgery (SEPS), perforator vein sclerotherapy, ultrasound therapy, and complete excision of LDS followed by split-thickness skin graft repair.*

Specific Investigations

- Biopsy
- Duplex ultrasound
- Laser Doppler scanning
- Ultrasound indentometry
- Capillary microscopy
- Magnetic resonance imaging

The clinical spectrum of lipodermatosclerosis

Kirsner RS, Pardes JB, Eaglstein WH, Falanga V. J Am Acad Dermatol 1993; 28: 623–7.

The diagnosis of LDS is based on clinical findings. In most cases, biopsy is not advised because 50% of biopsy sites do not heal.

Acute lipodermatosclerosis is associated with venous insufficiency

Greenberg A, Hasan A, Montalvo BM, Falabella A, Falanga A. J Am Acad Dermatol 1996; 35: 566–8.

One third to one fifth of patients with acute LDS lack evidence of venous disease with routine venous evaluation. Chronic LDS may present after or independently of acute LDS.

Lipodermatosclerosis: the histologic spectrum with clinical correlation to the acute and chronic forms

Hurwitz D, Kirsner RS, Falanga V, Elgard GW. J Clin Pathol 1996; 23: 78.

Biopsy specimens of acute LDS showed little epidermal change or capillary proliferation. In the subcutis, there was lobular and septal panniculitis with eosinophils, fibrin thrombi, and purpura. Biopsies of chronic LDS showed dermal changes associated with venous insufficiency, including capillary proliferation, hemosiderin deposition, and fibrosis. Epidermal hypertrophy was also found.

Lipodermatosclerosis: a clinicopathological study of 25 cases

Walsh SN, Santa Cruz DJ. J Am Acad Dermatol 2010; 62: 1005–12.

Biopsies may distinguish LDS from other fibrosing entities. Most cases show pseudoxanthoma elasticum–like elastic fiber calcification within the septae.

Skin iron deposition characterises lipodermatosclerosis and leg ulcer

Caggiati A, Rosi C, Casini A, Cirenza M, Petrozza V, Acconcia MC, et al. Eur J Vasc Endovasc Surg 2010; 40: 777–82.

Lipodermatosclerosis is always accompanied by hemosiderin deposition.

Duplex venous imaging: role for a comprehensive lower extremity examination

Badgett DK, Comerota MC, Khan MN, Eid IG, Kerr RP, Comerota AJ. *Ann Vasc Surg* 2000; 14: 73–6.

Results of duplex scanning of 205 lower extremities with varices: 106 not previously operated and 99 previously operated for varicose veins

Egeblad K, Baekgaard N. *Ugeskr Laeger* 2003; 3016–8.

Color duplex ultrasound can accurately detect the specific location of lower extremity venous insufficiency that often leads to LDS.

Quantifying fibrosis in venous disease: mechanical properties of lipodermatosclerosis and healthy tissue

Geyer MJ, Brienza DM, Chib V, Wang J. *Adv Skin Wound Care* 2004; 17: 131–42.

Ultrasound indentometry was used to quantify fibrotic tissue in LDS.

Excision of lipodermatosclerotic tissue: an effective treatment for non-healing venous ulcer

Ahnlide I, Bjellerup M, Akesson H. *Acta Derm Venereol* 2000; 80: 28–30.

In seven cases, laser Doppler scanning showed an increase in blood flow in lipodermatosclerotic skin, which decreased after surgical removal of the affected area.

Microangiopathy in chronic venous insufficiency: quantitative assessment by capillary microscopy

Howlader MH, Smith PD. *Eur J Vasc Endovasc Surg* 2003; 26: 325–31.

Advanced venous disease (LDS and healed ulcer) was associated with a reduced number of capillaries and increased capillary convolution.

Magnetic resonance imaging as a diagnostic tool for extensive lipodermatosclerosis

Chan CC, Yang CY, Chu CY. *J Am Acad Dermatol* 2008; 58: 525–7.

In a single case, magnetic resonance imaging (MRI) was in agreement with histopathologic findings. Additional studies are necessary to validate this technique.

First-Line Therapies

• Compression therapy	A
• Stanozolol	B
• Compression therapy plus stanozolol	B
• HR (<i>O</i> -[beta-hydroxymethyl]-rutosides)	B

The clinical spectrum of lipodermatosclerosis

Kirsner RS, Pardes J, Eaglstein WH, Falanga VJ. Am Acad Dermatol 1993; 28: 623–7.

Traditionally LDS has been treated with compression using graded stockings or elastic bandages. The authors suggest open-toe and below-the-knee graded stockings, with 30- to 40-mm Hg pressure. Stockings with a zipper in the back are easier for elderly patients to use. Patients with acute LDS often have too much pain to use compression stockings; in these patients, stanozolol 2 mg twice daily dramatically reduced pain and tenderness.

Graduated compression stockings reduce lipodermatosclerosis and ulcer recurrence

Vandongen YK, Stacey MC. Phlebology 2000; 25: 33–7.

A randomized controlled trial of 150 patients showed that elastic stockings alone can improve the skin changes of LDS and lower risk of recurrence.

Removal of dermal edema with class I and II compression stockings in patients with lipodermatosclerosis

Gniadecka M, Karlsmark T, Bertram A. J Am Acad Dermatol 1998; 39: 966–70.

In this study, ultrasonography demonstrated that low levels of compression, class I (18–26 mm Hg), in lipodermatosclerosis are as effective as class II (26–36 mm Hg) in the removal of dermal edema.

Venous lipodermatosclerosis: treatment by fibrinolytic

enhancement and elastic compression

Burnand K, Clemenson G, Morland M, Jarrett PE, Browse NL. Br Med J 1980; 280: 7–11.

Stanozolol 5 mg twice daily with compression was shown to reduce extravascular fibrin and area of LDS but not leg dimensions. Patients reported improvement in LDS but could not distinguish response during placebo from stanozolol treatment.

Patients taking stanozolol should be carefully monitored for excessive fluid retention, hirsutism, acne, liver function, and plasma fibrinogen concentration. Stanozolol is contraindicated in patients with uncontrolled hypertension or congestive heart failure.

Acute lipodermatosclerosis: an open clinical trial of stanozolol in patients unable to sustain compression

Vesikovic J, Medenica LJ, Pavlovic MD. Dermatol Online J 2008; 14: 1.

In an open trial of 17 patients, stanozolol 2 mg twice daily, without compression, decreased pain and dermal thickness.

HR (Paroven, Venoruton; O-(beta-hydroxyethyl)-rutosides) in venous hypertensive microangiopathy

Incandela L, Belacaro G, Renton S, DeSanctis MT, Cesarone MR, Bavera P, et al. J Cardiovasc Pharmacol Ther 2002; 7: S7–10.

HR reduced signs and symptoms of chronic venous insufficiency and LDS.

Second-Line Therapies

• Superficial venous surgery	B
• Subfascial perforator endoscopic surgery (SEPS)	C
• Pentoxifylline	C

Long term results of compression therapy alone versus compression plus surgery in chronic venous ulceration (ESCHAR): randomised controlled trial

Gohel MS, Barwell JR, Taylor M, Chant T, Foy C, Earnshaw JJ, et al.

BMJ 2007; 335: 83.

Surgical correction of superficial venous reflux (saphenous vein ablation) with compression reduced ulcer recurrence at 4 years compared with treatment with compression alone.

The effects on LDS were not specifically mentioned in this study.

Midterm results of endoscopic perforator vein interruption for chronic venous insufficiency: lessons learned from the North American Subfascial Endoscopic Perforatory Surgery registry

Gioviczki P, Bergan JJ, Rhodes JM, Canton LG, Harmsen MS, Ilstrup DM. J Vasc Surg 1999; 29: 489–502.

In this prospective registry of 148 patients who underwent SEPS ablations for LDS, patients reported improved overall LDS symptoms, including less pain, edema, and hyperpigmentation, as well as more rapid ulcer healing. Seventy-one percent of patients had a concomitant venous procedure (e.g., saphenous vein ablation).

Pentoxifylline for treating venous leg ulcer

Jull AB, Waters J, Arroll B. Cochrane Database Syst Rev 2002; 1: CD001733.

Pentoxifylline is a dimethylxanthine derivative that increases red blood cell flexibility, alters fibroblast physiology, and stimulates fibrinolysis. The dose of 400 mg three times daily may be increased to 800 mg three times daily if no improvement occurs.

Pentoxifylline is a good alternative in those intolerant to stanozolol. Side effects include nausea, dizziness, heartburn, and, occasionally, vomiting.

Third-Line Therapies

• Ultrasound	D
• Excision of lipodermatosclerotic tissue	D
• Intralesional triamcinolone injections	D
• Hydroxychloroquine	D
• Danazol	E
• Oxandrolone	E
• Niacin	E
• Sclerotherapy	E
• Antibiotics	E
• Intralesional platelet-rich plasma	E
• Topical capsaicin	E

Ultrasound therapy for lipodermatosclerosis

Damian DL, Yiasemides E, Gupta S, Armour K. Arch Dermatol 2009; 145: 330–2.

Eight patients treated with 3-MHz continuous ultrasound three times weekly for 4 to 8 weeks showed decreased skin hardness and erythema. Patients also wore grade II compression stockings.

Excision of lipodermatosclerotic tissue: an effective treatment for nonhealing venous ulcer

Ahnlide I, Bjellerup M, Akesson H. Acta Derm Venereol 2000; 80: 28–30.

In this combined retrospective and prospective study, six of seven patients' nonhealing venous ulcers healed after excision of lipodermatosclerotic tissue and split-skin graft.

Surgical removal of ulcer and lipodermatosclerosis followed by

split-skin grafting (shave therapy) yields good long-term results in “non-healing” venous leg ulcers

Schmeller W, Gaber Y. Acta Derm Venereol 2000; 80: 267–71.

In 41 patients with LDS and recalcitrant leg ulcers, despite prior treatment with compression and surgical venous ablation, shave excision with meshed split-thickness skin grafts demonstrated 67% ulcer healing at an average follow-up of 2.4 years.

Intralesional triamcinolone in the management of lipodermatosclerosis

Campbell LB, Miller OF 3rd. J Am Acad Dermatol 2006; 55: 166–8.

A retrospective chart review of 28 patients showed improvement in pain, erythema, edema, and induration after one to three intralesional injections of 5 to 10 mg/mL triamcinolone.

Adjunct therapies were used in the majority of the patients.

Lipodermatosclerosis: improvement noted with hydroxychloroquine and pentoxifylline

Choonhakarn C, Chaowattanapanit S. J Am Acad Dermatol 2012; 66: 1013–4.

A retrospective chart review of 32 patients showed improvement in pain, erythema, edema, and induration after treatment with hydroxychloroquine (maximum <6.5 mg/kg/d) and pentoxifylline (1200 mg/d) within 2 weeks to 6 months.

An acute case of lipodermatosclerosis successfully treated with danazol

Hammerman S, Mamakos L, Falanga V. J Am Acad Dermatol 2012; 66 (Suppl 1): AB42.

One patient with LDS resistant to leg elevation, aspirin, and niacin was treated with oral danazol, with improvement of pain and disease extension. With 100 mg twice daily, erythema and induration also improved. After 4 months, the patient transitioned to compression only without recurrence of LDS.

Danazol is an anabolic androgen, with fibrinolytic activity similar to stanozolol.

Lipodermatosclerosis: successful treatment with danazol

Hafner C, Wimmershoff M, Lanthaler M, Vogt T. Acta Derm Venereol 2005; 85: 365–6.

Pain and induration from LDS improved after administration of 400 mg oral danazol daily.

Treatment of lipodermatosclerosis with oxandrolone in a patient with stanozolol-induced hepatotoxicity

Segal S, Cooper J, Bologna J. J Am Acad Dermatol 2000; 43: 558–9.

Oxandrolone is another anabolic androgen similar to stanozolol with known fibrinolytic activity but with a lower incidence of hepatotoxicity. A single patient with LDS initially improved within 2 weeks with stanozolol (2 mg daily) but developed hepatotoxicity. Oxandrolone 10 mg twice daily reduced pain and induration of the legs with 3 months of treatment.

Lipid lowering and enhancement of fibrinolysis with niacin

Holvoet P, Collen D. Circulation 1995; 92: 698–9.

Niacin, at 100 to 150 mg three to five times a day, improved the hyperlipidemia often associated with LDS. In large doses it causes vasodilation and stimulates fibrinolysis.

Niacin is another alternative for patients who cannot tolerate stanozolol.

The effect of ultrasound-guided sclerotherapy (UGS) of incompetent perforator veins on venous clinical severity and disability scores

Masuda EM, Kessler DM, Lurie F, Puggioni A, Kistner RL, Eklof B. J Vasc Surg 2006; 43: 551–6.

In this 68-patient series, ultrasound-guided sclerotherapy (UGS) was an effective modality in the treatment of incompetent perforator veins and associated venous hypertension.

Severe chronic venous insufficiency treated by foamed sclerosant

Pascarella L, Bergan JJ, Mekenas LV. Ann Vasc Surg 2006; 20: 83–91.

In this prospective study, sclerotherapy with 1% to 3% polidocanol foam with compression is superior to compression alone for venous ulcer healing.

Lipodermatosclerosis is not specifically addressed.

Hypodermatitis sclerodermiformis and unusual acid-fast bacteria

Cantwell A, Kelso D, Rowe L. Arch Dermatol 1979; 115: 449–52.

There is little evidence to support the use of antibiotics,

antiinflammatory agents, or antimetabolites.

Refractory lipodermatosclerosis treated with intralesional platelet-rich plasma

Jeong K, Shin M, Kim N. J Am Acad Dermatol 2011; 65: e157–8.

This is a single case report of LDS and recalcitrant venous leg ulcer treated intralesionally with the patient's own platelet-rich plasma. Ulcer healing occurred with improvement in LDS and no ulcer recurrence over 6 months.

Topical capsaicin for the treatment of acute lipodermatosclerosis and lobular panniculitis

Yosipovitch G, Mengesha Y, Facliaru D, David M. J Dermatolog Treat 2005; 16: 178–80.

Two cases of acute LDS resolved with topical capsaicin 0.075% applied five times daily to an area pretreated with topical anesthetic EMLA (eutectic mixture of lidocaine 2.5% and prilocaine 2.5%). Mechanism of action is unclear.

Livedo reticularis

Ruwani P. Katugampola, and Andrew Y. Finlay

Livedo reticularis (LR) is the netlike, mottled, violaceous discoloration of the skin secondary to dilatation and stagnation of blood within dermal capillaries. The unaffected normal-colored islands of skin are the areas where blood supply is sufficient; in the

network areas the supply is insufficient. This commonly occurs on the legs, arms, and trunk, but can be diffuse, and is more pronounced after exposure to cold. LR can be physiologic (cutis marmorata), can occur as a primary phenomenon (idiopathic LR), or secondary to a number of diseases that cause dermal vessel wall thickening and/or lumen occlusion. Secondary causes of LR include systemic lupus erythematosus, polyarteritis nodosa, antiphospholipid syndrome cryoglobulinemia, oxalosis, cholesterol emboli, hypercalcemia (secondary to malignancy, hyperparathyroidism, renal failure), underlying malignancy (as a paraneoplastic phenomenon), and medications. Idiopathic LR may be congenital (cutis marmorata telangiectatica congenita) or associated with painful ulcers (livedoid vasculitis) or with cerebrovascular involvement (Sneddon syndrome). LR has been reported as a paraneoplastic phenomenon associated with metastatic breast cancer, renal cell carcinoma, and multiple myeloma. LR has also been reported as a complication of accidental intraarterial filler injections, such as hyaluronic acid fillers and use of silicone implants for soft tissue augmentation.

Management Strategy

The etiology of physiologic and primary LR is unknown, and no definitive treatment is available. The management of primary LR depends on the presence of associated ulcers (anomalies [congenital form]) and systemic involvement (Sneddon syndrome). In secondary LR, the underlying cause needs to be identified and treated.

Physiologic LR, which occurs in healthy children and adults in response to cold weather, is diffuse, mild, temporary, and usually asymptomatic. No specific treatment is required for this condition except *avoidance of cold exposure*, protection from cold exposure with *warm clothing*, and *rewarming* the affected area.

Cutis marmorata telangiectatica congenita is rare and presents at birth or soon after birth. A small proportion of affected children have associated congenital anomalies such as hemangiomas, glaucoma, limb atrophy, cardiac malformation, or psychomotor retardation that need to be identified and referred for appropriate specialist care. The LR in these children usually spontaneously disappears or markedly improves with age.

Patients with Sneddon syndrome are at risk of cerebrovascular disease and may benefit from *antithrombotic treatment*. The timing of

such treatment is debated, as LR may precede the neurologic events by up to 10 or more years. Advice regarding other risk factors predisposing to cerebrovascular events such as smoking, obesity, hypertension, and oral contraceptives is important.

Although a number of agents, including antiplatelet therapy, danazol, pentoxifylline, and systemic steroids, have been used to treat ulcers associated with LR, no single agent has been shown to completely resolve the LR itself.

Several medications, including those used in dermatology, have been associated with LR. The decision to withdraw the suspected medication should be based on the clinical judgment, alternative treatments, and other side effects rather than the appearance of LR per se.

Specific Investigations

- Skin biopsies for microscopy and direct immunofluorescence (adults)
- Full blood count and renal function
- Rheumatologic serologic tests
- Cryoglobulin level
- Anticardiolipin antibodies
- Coagulation screen
- Serum lipid profile
- Serum calcium

A detailed clinical history followed by physical examination is essential, especially in diagnosing Sneddon syndrome, identifying congenital anomalies in infants, and in excluding secondary causes of LR. The histology of LR is noninflammatory thickening of dermal vessel walls with eventual occlusion of the lumen.

Livedo reticularis and related disorders

Dean SM. Curr Treat Options Cardiovasc Med 2011; 13: 179–91.

Livedo reticularis: a review of the literature

Sajjan VV, Lunge S, Swamy MB, Pandit AM. Indian Dermatol Online J 2015; 6: 315–21.

Both of these reviews of LR include an extensive list of its systemic

associations. The authors conclude that management of secondary LR should be directed toward the underlying cause and that all patients with either primary or secondary LR should be encouraged to avoid the use of tobacco and vasoconstricting medications.

Livedo reticularis: an update

Gibbs MM, English JC, Zirwas MJ. *J Am Acad Dermatol* 2005; 52: 1009–19.

The authors of this review conclude that several deep punch biopsies, at least one from the central normal skin and one from the peripheral violaceous skin, be obtained to identify causes of secondary LR. In addition to cold avoidance, limb elevation and compression stockings are suggested for symptomatic patients based on the authors' clinical experience.

The histopathological characteristics of livedo reticularis

In SI, Han JH, Kang HY, Lee ES, Kim YC. *J Cutan Pathol* 2009; 36: 1275–8.

A survey of 16 patients with LR concluded that multiple skin biopsies from both the peripheral erythematous and central whitish areas in LR increase diagnostic yield.

Diagnostic impact and sensitivity of skin biopsies in Sneddon's syndrome. A report of 15 cases

Wohlrab J, Fisher M, Wolter M, Marsch WC. *Br J Dermatol* 2001; 145: 285–8.

Deep 4-mm punch biopsies from the central white part of the LR demonstrated a sensitivity of 27% with one biopsy, 53% with two biopsies, and 80% with three biopsies of diagnosing Sneddon syndrome in clinically suspected cases. The authors concluded that the positive histology was important for commencing prophylaxis of cerebrovascular events in patients initially presenting with LR.

Livedo reticularis: an underutilized diagnostic clue in cholesterol embolization syndrome

Chaudhary K, Wall BM, Rasberry RD. *Am J Med Sci* 2001; 321: 348–51.

Six out of 8 patients with unexplained acute renal failure due to suspected cholesterol emboli syndrome (CES) demonstrated cholesterol emboli in skin biopsies of LR. Deep skin biopsies of LR are

proposed as a safe diagnostic procedure to confirm CES, thus avoiding increased morbidity associated with biopsy of visceral organs.

The spectrum of livedo reticularis and anticardiolipin antibodies

Asherson RA, Mayou SC, Merry P, Black MM, Hughes GRV. Br J Dermatol 1989; 120: 215–21.

In this retrospective study of 65 patients with LR (idiopathic and secondary), there was a statistically significant increase in the incidence of strokes, transient ischemic attacks, venous thrombosis, fetal loss, and valvular heart disease in 28 anticardiolipin-positive patients compared with 37 anticardiolipin-negative patients.

First-Line Therapy

• Aspirin	D (Sneddon syndrome)
-----------	----------------------

Sneddon's syndrome: generalized livedo reticularis and cerebrovascular disease – importance of hemostatic screening

Devos J, Bulcke J, Degreef H, Michielsen B. Dermatology 1992; 185: 296–9.

Two cases of Sneddon syndrome are described, one of whom was shown to have twice the normal level of tissue plasminogen activator antigen, fourfold the normal level of plasminogen activator inhibitor, abnormal thrombin time, and elevated levels of factor XII during a neurologic event. Aspirin was commenced at 300 mg daily with normalization of the hemostatic parameters after 4 months of treatment and freedom from neurologic symptoms at 10 months.

There was no change to the patient's LR with aspirin treatment.

Second-Line Therapies

• Corticosteroids	D
• Psoralen plus ultraviolet A phototherapy (PUVA)	D
• Pentoxifylline + methylprednisolone	E

Cholesterol emboli syndrome in type 2 diabetes: the disease history of a case evaluated with renal scintigraphy

Piccoli GB, Sargiotto A, Burdese M, Colla L, Bilucaglia D, Magnano A, et al. *Rev Diabetic Stud* 2005; 2: 92–6.

A 75-year-old obese, diabetic, hypertensive man with moderate dyslipidemia who developed CES after endovascular intervention manifesting as acute renal failure and LR of both feet.

Methylprednisolone 300 mg intravenously for 3 days followed by oral prednisolone 25 mg daily and tapered over 2 months, commenced in view of deteriorating renal function, resulted in improvement in serum creatinine and disappearance of LR within 2 days of starting treatment.

Livedo reticularis and livedoid vasculitis responding to PUVA therapy

Choi HJ, Hann SK. *J Am Acad Dermatol* 1999; 40: 204–7.

Two patients with ulcers due to livedoid vasculitis of the lower legs resistant to treatment with other systemic treatment, including aspirin, prednisolone, and pentoxifylline, were treated with systemic PUVA using methoxsalen. Only the lower legs were exposed to UVA initially with 4 J/cm² three times a week and subsequent 1 J/cm² increments. No significant ulcers had recurred at 3 and 6 months, follow-up of the two patients after the last treatment. Improvement in the discoloration of the skin affected by LR was noted in one of the patients at completion of PUVA treatment.

Widespread livedoid vasculopathy

Marzano AV, Vanotti M, Alessi E. *Acta Derm Venereol* 2003; 83: 457–60.

A 37-year-old woman with widespread LR and recurrent painful ulcers on all limbs, trunk, and scalp was treated with intravenous methylprednisolone 80 mg/day for 5 days, followed by intramuscular

and subsequent tapering oral dose to 32 mg/day and with pentoxifylline 400 mg twice daily for 2 months. There was a marked clinical improvement within 2 weeks of treatment, and the intensity of the LR faded but did not completely resolve.

Third-Line Therapies

• Chemical lumbar sympathectomy	C
• Withdrawal of causative medications (minocycline, interferon α 2b, or amantadine)	D
• Simvastatin	E

Chemical lumbar sympathectomy in the treatment of idiopathic livedo reticularis

Wang WH, Zhang L, Li X, Zhao J, Zhuang JM, Dong GX. J Vasc Surg 2015; 62: 1018–22.

Ten women with idiopathic LR were treated with L3–4 chemical lumbar sympathectomy (CLS) using 5% phenol, 2 mL in each injection site. Seven patients were “clear or almost clear” of LR after CLS; LR recurred in two of these patients ≤ 1 year during follow-up, but achieved “clear or almost clear” skin after repeat CLS.

The women recruited for this study were bothered by the social inhibition caused by LR and “showed a very strong desire for treatment by seeking medical treatment at least twice and waiting for at least 1 week to make a decision” [to have the procedure].

Minocycline induced arthritis associated with fever, livedo reticularis and pANCA

Elkayam O, Yaron M, Caspi D. Ann Rheum Dis 1996; 55: 769–71.

Three women treated with long courses of oral minocycline for acne developed LR of the lower legs associated with fever and arthritis/arthralgia associated with elevated titers of perinuclear neutrophil antibodies (pANCA) during treatment. Symptoms resolved after discontinuation of treatment but recurred after rechallenge. The specific outcome of LR after discontinuation of treatment is not clearly stated.

Livedo reticularis associated with interferon α therapy in two

melanoma patients

Ruiz-Genao DP, García-F-Villalta MJ, Hernández-Núñez A, Ríos-Buceta L, Fernández-Herrera J, García-Díez A. *J Eur Acad Dermatol Venereol* 2005; 19: 252–4.

Two patients treated with subcutaneous interferon $\alpha 2b$ as adjuvant therapy for malignant melanoma (American Joint Committee on Cancer stage IIA and IIB, respectively) developed LR on legs and trunk 2 weeks after commencing treatment. LR cleared completely with no further recurrence after treatment was discontinued for other reasons.

Amantadine-induced livedo reticularis – case report

Quaresma MV, Gomes AC, Serruya A, Vendramini DL, Braga L, Buçard AM. *An Bras Dermatol* 2015; 90: 745–7.

A 79-year-old man with Parkinson disease treated with amantadine, carbidopa, and levodopa developed LR. This resolved with the discontinuation of amantadine. Amantadine is one of the more common drugs to cause LR.

Livedo reticularis caused by cholesterol embolization may improve with simvastatin

Finch TM, Ryatt KS. *Br J Dermatol* 2000; 143: 1319–20.

A 69-year-old man with LR without ulceration of the legs extending to the lower abdomen due to cholesterol embolization failed to respond to low-dose aspirin and low-fat diet. Fasting serum cholesterol was 6.9 mmol/L⁻¹ and serum triglyceride was normal. Three months after initiation of simvastatin 10 mg daily the serum cholesterol decreased to 4.9 mmol/L⁻¹ with associated reduction in extent and prominence of the LR.

Livedoid vasculopathy

Sultan A. Mirza, Bethany R. Hairston, and Mark D.P. Davis

Livedoid vasculopathy, or livedoid vasculitis, is a painful ulcerative condition of the lower extremities with characteristic clinical and histopathologic features. Pain is a prominent feature, associated with infarctive, tiny, shallow ulcerations most often involving the legs around the feet and ankles. This condition is difficult to treat and often recalcitrant to therapy. Healed ulcers have the nonspecific appearance of atrophie blanche, characterized by smooth, porcelain-

white lesions surrounded by punctate telangiectasia and hyperpigmentation; this appearance also may be seen in the context of healed ulcers due to venous insufficiency.

Management Strategy

Clinicopathologic correlation for a diagnosis of livedoid vasculopathy is necessary before treatment options can be considered. Histologic identification of the characteristic segmental hyalinized appearance of the dermal blood vessels is important to exclude other causes of lower extremity ulcerative disease. Increasing numbers of reports suggest that the disease has a procoagulant predisposition, with both hereditary and acquired hypercoagulable states; therefore a comprehensive coagulation screen is recommended.

Typically shallow and numerous, the ulcers in livedoid vasculopathy are painful and slow healing. *Wound care* is an important facet of treatment. *Excellent dressings* and *topical products* are available to treat chronic ulcerative diseases, and selection depends on the moisture content of the wound and the possibility of superinfection. *Pain management* is also essential.

Because of the potential procoagulant mechanisms involved in disease etiology, medical therapy involves prevention and treatment of dermal vessel thrombosis and improvement of vascular perfusion. Medical management has included *aspirin (acetylsalicylic acid)*, *niacin (nicotinic acid)*, *pentoxifylline*, *dipyridamole*, *warfarin*, and *danazol*. Systemic corticosteroids are not considered a primary therapy; however, some patients' conditions have improved with immunosuppressants in combination therapy. *Psoralen with ultraviolet A (PUVA)* has also been used. Patients with livedoid vasculitis recalcitrant to traditional management have been treated with *minidose heparin*, *subcutaneous low-molecular-weight heparin injections*, *rivaroxaban*, *certain prostanoids*, *intravenous immunoglobulin (IVIG)*, and a *tissue-type plasminogen activator (tPA)*.

Specific Investigations

- Skin biopsy, including routine histology and direct immunofluorescence
- Wound and tissue cultures

- Hemogram
- Serum homocysteine
- Cryoglobulin
- Thrombophilia investigations: anticardiolipin antibody, anti- β_2 -glycoprotein I antibodies, factor V Leiden R506Q and prothrombin G20210A mutations, biologic activity and antigen levels of protein C and S, functional and immunologic levels of antithrombin III protein, detection of lupus anticoagulant, lipoprotein(a), and fibrinopeptide A levels
- Noninvasive venous and arterial function testing: continuous-wave Doppler, venous duplex imaging, plethysmography, and transcutaneous oximetry

Livedoid vasculopathy: an intriguing cutaneous disease

Criado PR, Rivitti EA, Sotto MN, Valente NYS, Aoki V, de Carvalho JF, et al. *An Bras Dermatol* 2011; 86: 961–77.

Livedoid vasculopathy was originally described as a clinical expression of vasculitis; however, current understanding of the main pathogenetic mechanism suggests a vasoocclusive phenomenon due to intraluminal thrombosis of dermal vessels. The authors review etiologic associations, publications on livedoid vasculopathy associated with hypercoagulable conditions, and options for treatment.

Livedoid vasculopathy: an in-depth analysis using a modified Delphi approach

Alavi A, Hafner J, Dutz JP, Mayer D, Sibbald RG, Criado PR, et al. *J Am Acad Dermatol* 2013; 69: 1033–42.

This article reviews nomenclature changes with this condition. An illustrative approach to diagnosis and review of treatments are well presented.

Association between peripheral vascular endothelial dysfunction and livedoid vasculopathy

Yang CH, Shen SC, Hui RC, Huang YH, Chu PH, Ho WJ. *J Am Acad Dermatol* 2012; 67: 107–12.

Sixteen patients diagnosed with livedoid vasculopathy were compared with 16 matched control subjects in this prospective study using flow-mediated vasodilation of the brachial artery, an indicator

of vascular endothelial function, using high-resolution, two-dimensional ultrasonic imaging. Peripheral vascular endothelial dysfunction was demonstrated in patients, providing some evidence of endothelial dysfunction in the development of the disease. Decreased nitric oxide bioavailability may be the main reason for this dysfunction; however, the authors noted that more studies are needed to clarify the mechanism.

Livedoid vasculopathy: further evidence for procoagulant pathogenesis

Hairston BR, Davis MD, Pittelkow MR, Ahmed I. Arch Dermatol 2006; 142: 1413–8.

This retrospective study of 45 patients with biopsy-proven livedoid vasculopathy analyzed the presence of coagulation abnormalities. The laboratory results revealed numerous heterogeneous coagulation abnormalities, including factor V Leiden mutations, protein C or S abnormalities, prothrombin G20210A gene mutations, lupus anticoagulant, anticardiolipin antibodies, and elevated homocysteine, thus providing further evidence of procoagulant mechanisms for this disease.

Livedoid vasculopathy: the role of hyperhomocysteinemia and its simple therapeutic consequences

Meiss F, Marsch WC, Fischer M. Eur J Dermatol 2006; 16: 159–62.

Hypercoagulability due to hyperhomocysteinemia was recognized as a potentially contributing factor to livedoid vasculopathy in a 49-year-old woman.

Livedoid vasculopathy and its association with factor V Leiden mutation

Yong AA, Tan AW, Giam YC, Tang MB. Singapore Med J 2012; 53: 258–60.

Two cases of livedo vasculopathy with factor V Leiden mutations are described.

Livedoid vasculopathy associated with heterozygous protein C deficiency

Boyvat A, Kundakci N, Babikir MO, Gurgey E. Br J Dermatol 2000; 143: 840–2.

Livedoid vasculitis in association with protein C deficiency is

described in one patient.

Livedoid vasculitis: a manifestation of the antiphospholipid syndrome

Acland KM, Darvay A, Wakelin SH, Russell-Jones R. Br J Dermatol 1999; 140: 131–5.

Four patients with ulcerative livedoid vasculitis are described, all of whom had associated elevated anticardiolipin antibody levels but no other evidence of systemic disease.

Atrophie blanche: a disorder associated with defective release of tissue plasminogen activator

Pizzo SV, Murray JC, Gonias SL. Arch Pathol Lab Med 1986; 110: 517–9.

Plasma from eight patients with atrophie blanche was analyzed for release of vascular tPA before and after venous occlusion. The average plasma level of releasable tPA was only 0.03 IU/mL compared with 0.70 IU/mL for 118 healthy controls.

First-Line Therapies

• Wound care (including bed rest and leg elevation)	C
• Aspirin	C
• Dipyridamole	C
• Pentoxifylline	D

Atrophie blanche: a clinicopathological study of 27 patients

Yang LJ, Chan HL, Chen SY, Kuan YZ, Chen MJ, Wang CN, et al. Changgeng Yi Xue Za Zhi 1991; 14: 237–45.

Twenty-seven patients were reviewed with respect to mean age at onset, disease duration, natural course, and clinical morphology. Thirteen patients responded to local wound care, bed rest, and low-dose aspirin plus dipyridamole as treatment for the first attack or recurrent episodes.

Livedoid vasculopathy associated with sickle cell trait: significant improvement on aspirin treatment

El Khoury J, Taher A, Kurban M, Kibbi AG, Abbas O. Int Wound J 2012; 9: 344–7.

The authors describe a patient with sickle cell trait diagnosed with livedoid vasculopathy; treatment with aspirin led to significant improvement in the cutaneous ulcers.

Livedo vasculitis: therapy with pentoxifylline

Sams WM Jr. Arch Dermatol 1988; 124: 684–7.

Eight patients with disease unresponsive to a variety of medications were treated with pentoxifylline. Three experienced complete healing and four were much improved, whereas only one was unchanged after treatment.

Second-Line Therapies

• Low-molecular-weight heparin	C
• Warfarin	D
• Hyperbaric oxygen	D
• Danazol	D

Frequency of thrombophilia determinant factors in patients with livedoid vasculopathy and treatment with anticoagulant drugs – a prospective study

Di Giacomo TB, Hussein TP, Souza DG, Criado PR. J Eur Acad Dermatol Venereol 2010; 24: 1340–6.

Thirty-four patients diagnosed with livedoid vasculopathy were tested for prothrombin time, activated partial thromboplastin time, antithrombin activity, protein C and S activity, anticardiolipin antibodies, lupus anticoagulant, prothrombin gene mutation, factor V Leiden mutation, methylenetetrahydrofolate reductase mutation,

plasma homocysteine, and fibrinogen; 18 (52%) presented laboratory abnormalities of procoagulant conditions. Thirteen of the 34 patients were treated with anticoagulant drugs (either warfarin or heparin), with clinical improvement in 11 patients.

Livedoid vasculopathy in a pediatric patient with elevated lipoprotein(a) levels: prompt response to continuous low-molecular-weight heparin

Goerge T, Weishaupt C, Metze D, Nowak-Göttl U, Sunderkötter C, Steinhoff M, et al. Arch Dermatol 2010; 146: 927–8.

The authors describe a pediatric patient with livedoid vasculopathy who had elevated levels of lipoprotein(a). Treatment with low-molecular-weight heparin (enoxaparin) showed remission of the ulcers and pain.

Treatment of livedoid vasculopathy with low-molecular-weight heparin: report of 2 cases

Hairston BR, Davis MD, Gibson LE, Drage LA. Arch Dermatol 2003; 139: 987–90.

Two patients with livedoid vasculitis recalcitrant to conventional first- and second-line therapies had a beneficial response to subcutaneous injections of low-molecular-weight heparin.

Difficult management of livedoid vasculopathy

Frances C, Barete S. Arch Dermatol 2004; 140: 1011.

Fourteen of 16 patients treated with either low-molecular-weight heparin or a vitamin K antagonist (fluindione) had more effective results than with antiplatelet drugs. One patient responded partially to aspirin and dipyridamole; the remaining patient responded to no treatments.

The authors recommend that the benefit-to-risk ratio, cost, and quality of life be considered when prescribing either low-molecular-weight heparin or vitamin K antagonists.

Ulcerations caused by livedoid vasculopathy associated with a prothrombotic state: response to warfarin

Davis MD, Wysokinski WE. J Am Acad Dermatol 2008; 58: 512–5.

Warfarin therapy healed ulcerations in a 50-year-old woman who had a lifelong history of painful ulcerations; the patient was a heterozygous carrier of factor V Leiden and prothrombin gene

mutations.

A case of livedoid vasculopathy associated with factor V Leiden mutation: successful treatment with oral warfarin

Kavala M, Kocaturk E, Zindanci I, Turkoglu Z, Altintas S. *J Dermatol Treat* 2008; 19: 121–3.

A 19-year-old man with a 4-year history of recurrent leg ulcerations had rapid improvement with oral warfarin therapy after laboratory diagnosis of protein C and factor V Leiden mutations.

Warfarin therapy for livedoid vasculopathy associated with cryofibrinogenemia and hyperhomocysteinemia

Browning CE, Callen JP. *Arch Dermatol* 2006; 142: 75–8.

A 50-year-old man with abnormal cryofibrinogen and homocysteine levels had a dramatic response to oral warfarin therapy after being refractory to treatment with multiple other medications.

Livedoid vasculopathy: long-term follow-up results following hyperbaric oxygen therapy

Juan WH, Chan YS, Lee JC, Yang LC, Hong HS, Yang CH. *Br J Dermatol* 2006; 154: 251–5.

Eight patients completed a prospective study evaluating the efficacy of hyperbaric oxygen on healing the ulcers of livedoid vasculopathy. Leg ulcers in all eight patients healed completely at a mean of 3.4 weeks; however, six patients had relapses of ulceration but responded to additional hyperbaric oxygen therapy.

Livedoid vasculopathy and high levels of lipoprotein(a): response to danazol

Criado PR, de Souza Espinell DP, Valentef NS, Alavi A, Kirsner RS. *Dermatol Ther* 2015; 28: 248–53.

The authors present four patients with livedoid vasculopathy who were successfully treated with low-dose danazol (200 mg daily orally); clinical characteristics and laboratory workup, including the level of lipoprotein(a), are also presented.

Low-dose danazol in the treatment of livedoid vasculitis

Hsiao GH, Chiu HC. *Dermatology* 1997; 194: 251–5.

Six of seven patients treated with low-dose danazol (200 mg daily orally) had rapid cessation of new lesion formation, prompt reduction

in pain, and healing of active ulceration.

Third-Line Therapies

• Tissue plasminogen activator	C
• Intravenous immunoglobulin	C
• PUVA	C
• Sulfapyridine	D
• Rivaroxaban	E
• Cilostazol	E
• Prostanoids (PGE-1, prostacyclin)	E

Tissue plasminogen activator for treatment of livedoid vasculitis

Klein KL, Pittelkow MR. Mayo Clin Proc 1992; 67: 923–33.

In a prospective study, six patients who had nonhealing ulcers caused by livedoid vasculitis and in whom numerous conventional therapies had failed were treated with low-dose tPA. In five of the six patients, dramatic improvement with almost complete healing of the ulcers occurred during hospitalization. Several were maintained with warfarin therapy after their inpatient treatment.

Successful long-term use of intravenous immunoglobulin to treat livedoid vasculopathy associated with plasminogen activator inhibitor-1 promoter homozygosity

Tuchinda P, Tammara A, Gaspari AA. Arch Dermatol 2011; 127: 1224–5.

A 33-year-old patient diagnosed with livedoid vasculopathy associated with plasminogen activator inhibitor-1 promoter homozygosity was treated with IVIG after failing antiinflammatory,

antiplatelet, and tPA therapies. She was successfully treated for over 4 years without complications with IVIG, 0.5 g/kg every 2 weeks, given intravenously by an implanted Port-A-Cath. The authors also describe several preventative regimens that may help to decrease the risk of thromboembolic events related to IVIG infusion.

Efficacy of intravenous immunoglobulins in livedoid vasculopathy: long-term follow-up of 11 patients

Monshi B, Posch C, Vujic I, Sesti A, Sobotka S, Rappersberger K. *J Am Acad Dermatol* 2014; 71: 738–44.

In this retrospective study, the authors analyzed IVIG therapy in 11 patients. Most patients received IVIG added to an existing regimen, primarily aspirin, oral anticoagulants, or low-molecular-weight heparin, alone or in combination. Reduction of disease activity and improved quality of life were achieved after 6 rounds of IVIG.

Refractory livedoid vasculitis responding to PUVA: a report of four cases

Tuchinda C, Leenutaphong V, Sudtim S, Lim HW. *Photodermatol Photoimmunol Photomed* 2005; 21:154–6.

Four patients with refractory livedoid vasculopathy responded to PUVA therapy; however, two of the four patients had recurrent lesions within a few months after cessation of therapy.

Livedoid vasculitis responding to PUVA therapy

Lee JH, Choi HJ, Kim SM, Hann SK, Park YK. *Int J Dermatol* 2001; 40: 153–7.

Eight patients treated with systemic PUVA had rapid cessation of new lesion formation, notable symptom relief, and complete healing of primary lesions without unacceptable adverse effects.

Clinical studies of livedoid vasculitis (segmental hyalinizing vasculitis)

Winkelmann RK, Schroeter AL, Kierland RR, Ryan TM. *Mayo Clin Proc* 1974; 49: 746–50.

Clinical, laboratory, and histologic studies of 37 patients with livedoid vasculitis were presented. Treatment options included niacin (nicotinic acid), which was effective because of the inhibiting effect of nicotinate on contraction of vascular smooth muscle of the skin. Nine of 12 patients had sustained remission of their livedoid vasculopathy.

Rest and wet-dressing therapy produced short remissions. Six of 11 patients responded to sulfapyridine, and 3 of 8 responded to guanethidine. Corticosteroids, sympathectomy, and other forms of chemotherapy were not successful.

Rivaroxaban prevents painful cutaneous infarctions in livedoid vasculopathy

Kerk N, Drabik A, Luger TA, Schneider SW, Goerge T. Br J Dermatol 2013; 168: 898–9.

Three patients were treated with rivaroxaban (10 mg daily) for livedoid vasculopathy. Pain levels and the frequency of new ulcers were noted to improve significantly within 1 month and 3 months, respectively.

Response of livedoid vasculopathy to rivaroxaban

Winchester DS, Drage LA, Davis MD. Br J Dermatol 2015; 172: 1148–50.

Two patients treated with rivaroxaban (10–20 mg daily) noted relief of pain and complete healing in ulcers within 2 months.

Cilostazol: a novel agent in recalcitrant livedoid vasculopathy

Mendiratta V, Malik M, Yadav P, Nangia A. Indian J Dermatol Venereol Leprol 2016; 82: 222–4.

A 25-year-old woman with recalcitrant livedoid vasculopathy was initially treated with oral cilostazol (50 mg daily), with reduction in pain and burning and improvement of the ulcers, then twice daily for a short time during a flare. Within a few months, medication was tapered off, and no relapse was noted within a year.

Treatment of livedoid vasculopathy with alprostadil (PGE-1): case report and review of published literature

Mofarrah R, Aberer W, Aberer E. J Eur Acad Dermatol Venereol 2013; 27: 252–4.

This article discusses the diagnosis and treatment of livedoid vasculopathy in patients. It examines a 47-year-old patient with livid reticular discoloration and ulceration on both legs. It informs of a vasodilatory effect of prostaglandins and that prostaglandin E1 (PGE-1) is a promising drug used for the treatment of livedoid vasculopathies.

Lyme borreliosis

Matthew Grant, and David Banach

Courtesy of Yale Dermatology Residents Slide Collection.

Lyme disease is a multisystem illness caused by spirochetes of the genus *Borrelia*. In North America, the causative agent is *Borrelia burgdorferi*, whereas in Europe, disease is caused primarily by *B. afzelii* and *B. garinii*. Clinical manifestations of Lyme disease depend on the stage of illness and may be limited to the skin or involve the nervous system, joints, or heart. Lyme disease is the most common vectorborne disease in the United States. It is endemic in the Northeast, the mid-Atlantic, and parts of Wisconsin and Minnesota. The most common vector for Lyme disease in the United States is the *Ixodes scapularis* tick. *I. pacificus* has been linked to transmission of *B. burgdorferi* in the northwestern United States.

Mice and deer are the major reservoirs of *B. burgdorferi*. After hatching in the spring, tick larvae acquire *B. burgdorferi* while feeding on white-footed mice. The following spring, the larvae develop into nymphs and are then capable of transmitting infection. Nymph or adult female forms slowly deposit spirochetes into human skin during feeding. Ticks must remain attached and feed for over 48 hours to transmit a sufficient inoculum of spirochetes for illness to occur.

Management Strategy

Routine antimicrobial prophylaxis or serologic testing after a tick bite is not recommended. It is reasonable to offer single-dose prophylaxis to patients residing in endemic areas who remove engorged *I. scapularis* ticks attached for >36 hours. This recommendation is based on the result of a randomized trial of single-dose doxycycline (200 mg), which prevented 87% of Lyme infections if administered within 72 hours of tick removal. Regardless of whether prophylaxis is taken, patients who remove a tick attached for more than a day should be monitored for up to 30 days for the occurrence of local skin lesions or fever.

The best mode of preventing Lyme disease is avoidance of tick-infested areas. If tick exposure is unavoidable, then one should ideally wear permethrin-treated clothes with long sleeves and long pants tucked into socks. Exposed skin should be treated with a DEET-based repellent, which has activity against ticks in addition to mosquitoes and most biting insects. Skin self-inspection within 36 hours of tick exposure and bathing within 2 hours of exposure have both been associated with decreased risk of developing Lyme borelliosis. Daily inspection of the entire body, including the scalp, is recommended because attached ticks removed within 24 to 36 hours are unlikely to transmit *B. burgdorferi*. *Ixodes* ticks are small: larvae are less than 1 mm in size, and adult females are 2 to 3 mm in size. Attached ticks should be removed with tweezers by carefully pulling on the mouth apparatus close to the skin, taking care not to retain mouth parts of the embedded tick.

Lyme disease generally occurs in stages, with different signs and symptoms at each stage. Therapeutic recommendations vary depending on the stage of disease and the presence of extracutaneous manifestations.

Early localized Lyme disease

The most common clinical manifestation of early Lyme disease is erythema migrans (EM). This characteristic skin lesion occurs at the site of the bite a median of 10 days after inoculation, beginning as an erythematous papule and evolving into an expanding annular patch with a distinct edge. Although central clearing of erythema leading to a bull's-eye or targetoid appearance is characteristic, many lesions do not demonstrate this finding, and absence of central clearing should not exclude an EM diagnosis. The lesion may be accompanied by nonspecific symptoms, including fever, regional lymphadenopathy, arthralgia, fatigue, and headache. About 75% of patients with Lyme disease in the United States are diagnosed during the early localized stage with a single primary lesion. Untreated lesions usually fade within 3 to 4 weeks.

Administration of doxycycline 100 mg twice daily, amoxicillin 500 mg three times daily, or cefuroxime axetil 500 mg twice daily for at least 14 days is recommended for early localized or early disseminated Lyme disease associated with EM. Doxycycline has the advantage of also treating human granulocytic anaplasmosis caused by *Anaplasma phagocytophilum*, which can be cotransmitted by *I. scapularis* bites. Doxycycline can cause photosensitivity and is contraindicated during pregnancy or breastfeeding and for children less than 8 years old.

A rare skin manifestation of early Lyme infection described predominantly in Europe is borrelial lymphocytoma (BL). This solitary bluish-red nodule occurs at the site of a tick bite typically preceding or concomitantly with EM. Commonly involved sites are the ear lobes in children and near or on the nipple in adults. BL may develop within weeks to months after a tick bite and if untreated can persist for months to years. Treatment regimens used to treat EM can be used to treat BL.

Early disseminated Lyme disease

Early dissemination of the spirochete occurs via blood or lymphatics over several weeks in untreated infection. Multiple annular skin lesions resembling primary EM can arise when spirochetes are deposited at skin sites remote from the initial bite—notably these lesions are generally smaller. Other common symptoms include fever,

lethargy, myalgia, headache, and neck stiffness. Patients may present with atrioventricular (AV) conduction disturbances, iritis or uveitis, aseptic meningitis (lymphocytic pleocytosis in cerebrospinal fluid [CSF] with normal glucose), cranial nerve palsies (notably facial nerve palsies), or peripheral radiculopathy. In adults, intravenous ceftriaxone 2 g daily for 14 to 28 days is recommended for early Lyme disease presenting with neurologic or advanced cardiac conduction abnormalities. Parenteral penicillin or cefotaxime are second-line agents. Temporary pacing may be required for patients with high-degree AV block (PR interval ≥ 0.30 seconds). Insertion of a permanent pacemaker is not necessary, as conduction defects usually resolve with medical treatment alone. Isolated facial nerve palsy and first-degree AV block can be treated with oral doxycycline.

Late Lyme disease

Late Lyme disease can occur months to years after previously untreated or inadequately treated initial infection. Lyme arthritis is the most common manifestation of late Lyme disease, although its incidence is decreasing due to improved recognition of early disease. Lyme arthritis is oligoarticular and presents as recurrent swelling of large joints, primarily the knees. Persistent swelling is atypical. Positive serologic testing is required to confirm the diagnosis, and positive polymerase chain reaction (PCR) results from synovial fluid strengthen the diagnosis.

Late neuroborreliosis is rare and can manifest as peripheral neuropathy, encephalomyelitis, or a subacute encephalopathy characterized by memory disturbances, mood alterations, and somnolence.

A rare dermatologic finding associated with late Lyme disease is acrodermatitis chronica atrophicans (ACA). ACA has been predominantly described in elderly female patients and has rarely been seen in the United States but is more common in European patients with *B. afzelii*. ACA presents months to years after initial infection with a poorly demarcated area of violaceous discoloration and swelling of involved skin. These lesions usually involve the extensor surfaces of the extremities, including the dorsum of the hands. Over time the lesions become atrophic, with a characteristic hyperpigmented, hairless, and translucent appearance. Involvement of peripheral nerves can also result in sensory neuropathy.

Lyme arthritis without neurologic symptoms can be treated with a 28-day oral regimen of either doxycycline 100 mg twice daily or amoxicillin 500 mg three times daily. Adults with evidence of concurrent neurologic involvement should receive intravenous ceftriaxone. Recurrent or persistent joint swelling after an oral regimen can be retreated with another 28-day course of oral antimicrobials or with a 2- to 4-week parenteral regimen. Adults with late neurologic disease should be treated with a parenteral regimen for 2 to 4 weeks. Repeated or prolonged therapy is not recommended.

Posttreatment symptoms

Persistent arthritic complaints appear to be immunologically mediated and are most common in individuals with the HLA-DR4 haplotype. Research studies have not consistently demonstrated microbiologic persistence of *Borrelia* in patients with symptoms after completion of treatment for Lyme. Moreover, prolonged or multiple courses of antimicrobials are unhelpful and may be harmful. Symptomatic treatment with nonsteroidal agents, intraarticular corticosteroids, disease-modifying antirheumatic drugs, or in severe nonremitting cases, arthroscopic synovectomy may provide relief.

Reinfection and vaccination

Patients treated for early Lyme disease, specifically EM, do not develop protective immunity and if reexposed may become reinfected. The clinical presentation associated with reinfection is similar to primary infection. At this time there is no vaccine available to protect against Lyme disease.

Specific Investigations

Testing

Prospective study of serologic tests for Lyme disease

Steere A, McHugh G, Damle N, Sikand V. Clin Inf Dis 2008; 47: 188–95.

Early Lyme disease is a clinical diagnosis with 80% of patients in endemic areas presenting with EM. Only one third of patients

presenting with EM and early Lyme disease have positive serology, but sensitivity increases during the convalescent phase. Two-step testing with enzyme-linked immunosorbent assay (ELISA) and Western immunoblot remains the gold standard for diagnosing later stages of Lyme disease. In this study, over 90% of patients with disseminated disease and 100% of patients with late Lyme disease had positive two-step test results. The authors were also able to demonstrate increased sensitivity using a single-step IgG C6 peptide ELISA. This test warrants further investigation in a broader patient population.

Prevention

Peridomestic Lyme disease prevention. Results of a population based case-control study

Connally NP, Durante AJ, Yousey-Hindes M, Meek JI, Nelson RS, Heimer R. Am J Prev Med 2009; 37: 201–6.

This was a 32-month case-control study comparing 364 patients with Lyme disease to neighborhood-matched controls to evaluate the impact of prevention measures on risk. In multivariate analysis, checking for ticks within 36 hours after spending time in the yard, bathing within 2 hours after exposure, and fencing around the yard were associated with decreased risk of EM.

Prophylaxis

Prophylaxis with single-dose doxycycline for the prevention of Lyme disease after an *Ixodes scapularis* tick bite

Nadelman RB, Nowakowski J, Fish D, Falco RC, Freeman K, McKenna D, et al; Tick Bite Study Group. N Engl J Med 2001; 345: 79–84.

In this investigation, 482 patients were randomized to receive 200 mg doxycycline or placebo within 72 hours of removal of an *I. scapularis* tick. One of 235 subjects (0.4%) who received doxycycline, compared with 8 of 247 (3.2%) who received placebo, developed EM. No asymptomatic seroconversions occurred and no subject developed extracutaneous Lyme disease. Prophylaxis was effective at decreasing the development of Lyme disease. More gastrointestinal symptoms occurred with doxycycline.

Treatment

The clinical assessment, treatment, and prevention of Lyme disease, human granulocytic anaplasmosis, and babesiosis: clinical practice guidelines by the Infectious Diseases Society of America

Wormser GP, Dattwyler RJ, Shapiro ED, Halperin JJ, Steere AC, Klemperner MS, et al. Clin Infect Dis 2006; 43: 1089–134.

First-Line Therapies

Early localized disease (erythema migrans)*

• Doxycycline [†] 100 mg twice daily for 14 days	A
• Amoxicillin 500 mg three times daily for 14 days	A
• Cefuroxime axetil 500 mg twice daily for 14 days	A

Early neurologic (meningitis or radiculopathy)

• Ceftriaxone 2 g IV daily for 14 days	B
• Penicillin G 18–24 million units IV daily (divided and dosed every 4 hours) for 14 days	B

Cardiac disease including atrioventricular block

• Can be treated with oral or parenteral regimens recommended for early localized or early neurologic disease for 14 days [‡]	C
--	---

Lyme arthritis without neurologic involvement

• Doxycycline [†] 100 mg twice daily for 28 days or amoxicillin 500 mg three times daily for 28 days	B
---	---

Lyme arthritis with neurologic involvement

• Ceftriaxone 2 g IV daily for 14–28 days	B
• Penicillin G 18–24 million units IV daily (divided and dosed every 4 hours) for 14–28 days	B

Recurrent arthritis

- | | |
|--|----------|
| • Retreatment with a 28-day course of oral antibiotics | D |
|--|----------|

Late neuroborreliosis

• Ceftriaxone 2 g IV daily for 14–28 days	B
• Penicillin G 18–24 million units IV daily (divided and dosed every 4 hours) for 14–28 days	B

Acrodermatitis chronic atrophicans

• Doxycycline 100 mg twice daily for 21 days	C
• Amoxicillin 500 mg three times daily for 21 days	C
• Cefuroxime axetil 500 mg twice daily for 21 days	D

* Level B recommendation for borrelial lymphocytoma and early Lyme disease with isolated cranial nerve palsy.

† Doxycycline is contraindicated in pregnancy and in children <8 years old.

‡ Initial treatment with parenteral regimen recommended in hospitalized patients.

Second-Line Therapies

Early localized disease

• Erythromycin 250 mg orally four times daily for 14 days	B
• Azithromycin 500 mg daily for 7 days	B

Neurologic involvement or advanced cardiac conduction block

• Doxycycline 100 mg twice a day for 10–28 days	B
---	----------

Second-line therapies are to be used in the setting of

contraindication to first-line treatments (e.g., severe allergy).

Amoxicillin plus probenecid versus doxycycline for treatment of erythema migrans borreliosis

Dattwyler RJ, Volkman DJ, Conaty SM, Platkin SP, Luft BJ. Lancet 1990; 336: 1404–6.

Seventy-two adults with early Lyme disease were randomized to either amoxicillin 500 mg three times daily or doxycycline 100 mg twice daily for 3 weeks. Both groups had 100% cure rates of their EM and were asymptomatic after a 6-month follow-up period.

Comparison of cefuroxime axetil and doxycycline in the treatment of early Lyme disease

Nadelman RB, Luger SW, Frank E, Wisniewski M, Collins JJ, Wormser GP. Ann Intern Med 1992; 117: 273–80.

A randomized, multicenter, investigator-blinded trial treated 123 patients with EM for 20 days with either cefuroxime axetil 500 mg twice daily ($n=63$) or doxycycline 100 mg twice daily ($n=60$). Cure or improvement was achieved in 51 of 55 (93%) evaluable patients treated with cefuroxime axetil and in 45 of 51 (88%) patients treated with doxycycline. At 1-year post treatment, the percentage of patients who achieved a satisfactory outcome was comparable between the two groups. Cefuroxime was associated with more diarrhea than was doxycycline and is more expensive than doxycycline or amoxicillin.

Two controlled trials of antibiotic treatment in patients with persistent symptoms and a history of Lyme disease

Klempner MS, Hu LT, Evans J, Schmid CH, Johnson GM, Trevino RP, et al. N Engl J Med 2001; 345: 85–92.

Patients with persistent symptoms after previously treated Lyme disease were randomized to receive either intravenous ceftriaxone 2 g daily for 30 days followed by oral doxycycline 200 mg daily for 60 days or matching placebos. This study was halted after planned interim analysis of the first 107 subjects indicated that the study would be unlikely to reveal a significant difference in outcomes.

Azithromycin compared with amoxicillin in the treatment of erythema migrans. A double-blind, randomized, controlled trial

Luft BJ, Dattwyler RJ, Johnson RC, Luger SW, Bosler EM, Rahn DW, et al. Ann Intern Med 1996; 124: 785–91.

In this report, 246 adults with EM were randomized to either amoxicillin 500 mg three times daily for 20 days or azithromycin 500 mg once daily for 7 days. Those treated with amoxicillin were more likely to achieve complete resolution of disease at day 20 (88% for amoxicillin compared with 76% for azithromycin; $p=0.024$). More azithromycin recipients (16%) than amoxicillin recipients (4%) had relapses.

Treatment of Erythema Migrans With Doxycycline for 10 Days Versus 15 Days

Stupica D, Lusa L, Ruzić-Sabljić E, Cerar T, Strle F. Clin Infect Dis 2012; 55: 343–50.

In this study 117 patients with EM received doxycycline 100 mg twice daily for 10 or 15 days. Resolution of EM was similar in both groups, and at 12 months 93% of the 15-day group and 92% of patients in the 10-day group showed complete response, and most had complete response within 2 months. There was a higher rate of photosensitivity in the 15-day group.

Antibiotic treatment duration and long-term outcomes of patients with early Lyme disease from a Lyme disease hyperendemic area

Kowalski TJ, Tata S, Berth W, Mathiason MA, Agger WA. Clin Infect Dis 2010; 50: 512–20.

This retrospective cohort study provides follow-up data of 617 patients diagnosed with early localized or disseminated Lyme disease. The 2-year treatment failure-free survival rates of patients treated with ≤ 10 , 11 to 15, and ≥ 16 days of antibiotics were 99.0%, 98.9%, and 99.2%, respectively.

Lymphangioma circumscriptum

Patrick O.M. Emanuel, and Kevin McKerrow

Lymphangioma circumscriptum is an uncommon lymphatic malformation. It presents on the skin surface as grapelike groups of thin-walled, translucent, lymph-filled vesicles, often compared with frog spawn. Hemorrhage within the lesions can create a deep red or black appearance.

More commonly congenital, they are typically noted at birth or appear during childhood. They are most commonly found around the shoulder girdle and proximal limbs. There is a morphologically identical acquired variant related to lymphatic obstruction as a

consequence of surgery, radiation, or malignancy.

Management Strategies

Although observation is an appropriate option for many cases, cosmetic concern is the typical indication for treatment. Other indications may include persistent leakage of lymphatic fluid or blood and recurrent infection. The risk of developing angiosarcoma and squamous cell carcinoma is trivial and should not be used to rationalize full surgical excision.

Treatment is challenging and often thwarted by local recurrences due to the persistence of deep lymphatic cisterns, which may delve deep into the subcuticular adipose tissue, skeletal muscle, and nerves. Every treatment option has associated recurrence rates/complication profiles. Consequently, there is disagreement in the literature as to which treatment option is the most effective. Although *complete surgical excision* has the lowest recurrence rates, it has the highest rate of complications; more extensive lesions may be deemed inoperable.

Sclerotherapy using a variety of sclerosants has been advocated as a less invasive and effective treatment modality, which is either a first-line alternative or an adjunct to surgery.

Other authorities suggest that after definitive diagnosis and radiologic mapping, surgical excision and postoperative histologic assessment of excision margins provide the most effective treatment options.

Resurfacing of the lesions can be attempted and achieved even if proper surgical excision is not possible and/or sclerotherapy fails, but recurrence rates are usually higher than with other therapies. The high-energy, short-pulse CO₂ laser has been found to yield functionally and cosmetically acceptable results. This seals communicating channels to the deeper cisterns by vaporizing the superficial lymphatics and is said to have fewer complications than more aggressive treatment alternatives. Other laser methods, particularly the pulsed dye laser, have also been shown to be effective in selected superficial cases.

Specific Investigations

- Biopsy

- Imaging studies
- Magnetic resonance imaging (MRI)
- Lymphangiography
- Ultrasound

In the majority of cases the clinical diagnosis is straightforward. In some, the differential diagnosis may be broad: genital lesions are often associated with verrucous changes, which give them a warty appearance and are often confused with viral warts or squamous cell carcinoma; discoloration of the vesicles can lead to confusion with hemangiomas and even malignant melanoma; herpetic infection and dermatitis herpetiformis are less frequent differential diagnoses. Biopsy is diagnostic for clinically unusual cases and exhibits numerous thin-walled, dilated lymphatic channels encroaching onto the epidermis (which may become hyperkeratotic), expanding the papillary dermis and extending deep into the dermis and subcutis. Immunostaining with VEGFR3 and D2-40 decorates the vessels and confirms their lymphatic origin.

MRI can define the entire anatomy of a lesion and, when used preoperatively, can help prevent unnecessarily extensive or incomplete surgical resection. Computed tomography (CT), ultrasound, and lymphoscintigraphy have also been useful in determining the extent of a lesion.

Secondary lesions may be investigated for an underlying cause if the cause is not clinically obvious. Lymphangiomas may be associated with rare disorders such as Proteus, Cobb, and Klippel–Trenaunay syndromes, and so appropriate investigations and consultations should be sought if these conditions are suspected.

First-Line Therapies

• Conservative/observation	A
• Antibiotics	D
• Sclerotherapy	A
• OK-432	A
• Hyperosmolar saline	D
• Sodium tetradecyl sulfate	E
• Surgery	A

Intralesional sclerotherapy with group A *Streptococcus pyogenes* of human origin (OK-432) has emerged as an effective sclerosing agent.

OK-432 therapy in 64 patients with lymphangioma

Ogita S, Tsuto T, Nakamura K, Deguchi E, Iwai N. J Pediatr Surg 1994; 29: 784–5.

A case of unresectable lymphangioma circumscriptum of the vulva successfully treated with OK-432 in childhood

Ahn SJ, Chang SE, Choi JH, Moon KC, Koh JK, Kim DY. J Am Acad Dermatol 2006; 55: S106–7.

Treatment of lymphangioma in children: our experience of 128 cases

Okazaki T, Iwatani S, Yanai T, Kobayashi H, Kato Y, Marusasa T, et al. J Pediatr Surg 2007; 42: 386–9.

The main advantage of OK-432 over other sclerosing agents is the absence of perilesional fibrosis. OK-432 is an effective agent for cases of a single or limited numbers of vesicles. In larger lesions the

technique is useful as a pretreatment adjunct to surgical excision.

Treatment of lymphangioma circumscriptum with sclerotherapy: an ignored effective remedy

Al Ghamdi KM, Mubki TF. *J Cosmet Dermatol* 2011; 10: 156–8.

Lymphangioma circumscriptum: treatment with hypertonic saline sclerotherapy

Bikowski JB, Dumont AM. *J Am Acad Dermatol* 2005; 53: 442–4.

Hypertonic saline has been reported to be effective for the management of lymphangioma circumscriptum to the shoulder, although wider use of this agent in comparison with other treatments for lymphangioma circumscriptum has not been reported.

Percutaneous sclerotherapy of lymphangioma

Molitch HI, Unger EC, Witte CL, van Sonnenberg E. *Radiology* 1995; 194: 343–7.

Five patients with unresectable lymphangiomas of the pelvis ($n = 2$), neck ($n = 1$), abdomen ($n = 1$), or leg ($n = 1$) were treated at two medical centers with sclerotherapy, using doxycycline as the sclerosant.

Treatment of unusual vascular lesions: usefulness of sclerotherapy in lymphangioma circumscriptum and acquired digital arteriovenous malformation

Park CO, Lee MJ, Chung KY. *Dermatol Surg* 2005; 31: 1451–3.

Two cases of lymphangioma circumscriptum were treated with a sclerosant, sodium tetradecyl sulfate, and were almost cleared with several treatments of sclerotherapy.

Surgery

Treatment of lymphangioma in children: our experience of 128 cases

Okazaki T, Iwatani S, Yanai T, Kobayashi H, Kato Y, Marusasa T, et al. *J Pediatr Surg* 2007; 42: 386–9.

Primary surgical excision was significantly more successful than sclerotherapy, but the results are often unsatisfactory because of complications, including damage to surrounding structures,

particularly nerves and blood vessels, scarring, and recurrence due to incomplete excision. Ultrasound and MRI demonstrate deep cisterns, thereby ensuring deeper excision of these structures and less risk of recurrence.

Surgical management of “lymphangioma circumscriptum.”

Browse NL, Whimster I, Stewart G, Helm CW, Wood JJ. Br J Surg 1986; 73: 585–9.

Confirmation of the completeness of excision can be obtained using frozen section analysis of the lateral and deep margins.

Lymphangioma circumscriptum of the vulva mimicking genital wart: a case report and review of literature

Sah SP, Yadav R, Rani S. J Obstet Gynaecol Res 2001; 27: 293–6.

A case report of vulval lymphangioma circumscriptum, clinically diagnosed as a genital wart. After biopsy, the patient required extensive vulval surgery, and there was no recurrence after 16 months.

Surgical management of penoscrotal lymphangioma circumscriptum

Latifoglu O, Yavuzer R, Demir Y, Ayhan S, Yenidünya S, Atabay K. Plast Reconstruct Surg 1999; 103: 175–8.

An extensive lymphangioma circumscriptum of the penis and scrotum that was treated by wide excision in single-stage surgery. At the fourteenth postoperative month the patient was free of recurrence.

Lymphangioma circumscriptum: pitfalls and problems in definitive management

Bond J, Basheer MH, Gordon D. Dermatol Surg 2008; 34: 271–5.

Two cases of surgical excision with no recurrence at 1 and 2 years. Imaging of deep communicating structures and histologic assessment of excision margins provide the greatest chance of nonrecurrence.

Second-Line Therapies

• CO ₂ laser	D
• Pulsed dye laser	D
• Radiotherapy	E
• Cryotherapy	D
• Argon laser	D
• Suction-assisted lipectomy	D
• Topical imiquimod	D

Carbon dioxide laser vaporization of lymphangioma circumscriptum

Bailin PL, Kantor GR, Wheeland RG. J Am Acad Dermatol 1986; 14: 257–62.

CO₂ laser in a vaporization mode successfully ablated superficial cutaneous lesions in seven patients with lymphangioma circumscriptum.

Lymphangioma circumscriptum: review and evaluation of carbon dioxide laser vaporization

Eliezri YD, Sklar JA. J Dermatol Surg Oncol 1988; 14: 357–64.

Three patients were treated with CO₂ laser vaporization, with good to excellent cosmetic results and complete resolution of their symptoms.

CO₂ laser therapy of vulval lymphangiectasia and lymphangioma circumscriptum

Huilgol SC, Neill S, Barlow RJ. Dermatol Surg 2002; 28: 575–7.

Focal recurrence and an area of localized persistence were noted in

both patients with lymphangioma circumscriptum treated with CO₂ laser therapy.

CO₂ laser therapy of vulval lymphangiectasia and lymphangioma circumscriptum

Haas AF, Narurkar VA. Dermatol Surg 1998; 24: 893–5.

A difficult case of lymphangioma circumscriptum was treated successfully with a high-energy, short-pulse CO₂ laser after two failed surgical excisions.

CO₂ laser ablation of lymphangioma circumscriptum of the scrotum

Treharne LJ, Murison MS. Lymphat Res Biol 2006; 4: 101–3.

Widespread disease of the scrotum had excellent symptomatic relief after treatment with the CO₂ laser.

Treatment of lymphangioma circumscriptum with the intense pulsed light system

Thissen CA, Sommer A. Int J Dermatol 2007; 46: 16–8.

An intense pulsed light source led to good cosmetic results.

Treatment of lymphangioma circumscriptum with combined radiofrequency current and 900 nm diode laser

Lapidoth M, Ackerman L, Amitai DB, Raveh E, Kalish E, David M. Dermatol Surg 2006; 32: 790–4.

Treatment was rated as “excellent” in four patients and “good” in two. Swelling, erythema, and pain were present in all patients and ulcers and scarring in two.

Lymphangioma circumscriptum treated with pulsed dye laser

Lai CH, Hanson SG, Mallory SB. Pediatr Dermatol 2001; 18: 509–10.

A child with a symptomatic lymphangioma circumscriptum was treated with pulsed dye laser, with good results.

Radiotherapy in congenital vulvar lymphangioma circumscriptum

Yildiz F, Atahan IL, Ozhar E, Karcaaltincaba M, Cengiz M, Ozyigit G, et al. Int J Gynecol Cancer 2008; 18: 556–9.

A patient was treated successfully with a course of external

radiotherapy after failed attempts with sclerosing agents and surgery.

**Radiotherapy is a useful treatment for lymphangioma
circumscriptum: a report of two patients**

Denton AS, Baker-Hines R, Spittle MF. Clin Oncol (R Coll Radiol) 1996; 8: 400–1.

Localized radiotherapy has been successfully used.

**Treatment of lymphangioma circumscriptum with topical
imiquimod 5% cream**

Wang JY, Liu LF, Mao XH. Dermatol Surg 2012; 38: 1566–9.

Lymphedema

Peter C. Lambert, Giuseppe Micali, and Robert A. Schwartz

Lymphedema is a chronic, progressive, and sometimes debilitating condition. It is due to abnormal accumulation of protein-rich lymphatic fluid in interstitial spaces. Lymphedema is classified into primary and secondary types.

Primary lymphedema is caused by a developmental malformation of the lymphatic system. It may be classified by age of onset into congenital lymphedema, lymphedema praecox, and lymphedema tarda. Primary congenital lymphedema, or Milroy disease, occurs at age less than 2 years and is an uncommon autosomal dominant disorder due, in some families, to one of several known missense mutations that interfere with vascular endothelial growth factor-3

(VEGF-3) signaling, resulting in abnormal vascular lymphatic function. Lymphedema praecox, also known as *Meige disease*, has its onset between age 2 and 35 years, with a marked tendency to arise during puberty or during pregnancy. Finally, lymphedema tarda has an age of onset later than 35 years.

Secondary lymphedema is due to obstruction of or damage to an otherwise normal lymphatic system. Common causes are malignancy, surgery, radiation therapy, and, globally, filariasis.

Once lymphedema has become established, biophysical influences, such as the law of La Place (which causes dilated structures to expand, regardless of what caused them to begin with) and pathophysiologic responses, such as fibrosis, make it progressive and difficult to treat. Chronic lymphedema may lead to striking verrucous proliferative changes in the overlying skin known as *elephantiasis nostra*. Lymphedema may also predispose the affected tissue to recurrent infection and to a usually aggressive form of *angiosarcoma*, in a condition known as *Stewart–Treves syndrome*.

Management Strategies

Lymphedema must be distinguished from cutaneous and soft tissue lymphedema due to other causes, particularly of cardiac, hepatic, or renal etiology. Not infrequently, there may be more than one cause acting simultaneously or in sequence. Chronic lymphedema is characterized clinically by brawny, nonpitting edema, unlike lymphedema due to cardiac, hepatic, or renal causes, which tend to produce pitting edema. *Lymphoscintigraphy* (lymphography using an isotope; LSG) is a first-line imaging modality useful to evaluate and diagnose disorders of lymphatic vasculature.

The goal of therapy for lymphedema is to reduce stasis of protein-rich lymph in the interstitium and to improve outflow of the lymphatic circulation.

The primary treatment step should be a *conservative approach with medical and physical therapy*.

Complex decongestive therapy (CDT) is an effective first-line treatment option. CDT is a four-component plan composed of *multilayer compression bandaging, manual lymphatic drainage, skin care, and exercise*. Therapeutic efficacy is highly dependent on patient compliance. Because of this, strict adherence to the treatment protocol should be encouraged. *Pneumatic compression therapy* has been widely used to

control lymphedema as a second-line alternative approach. Because of its poor outcomes as a monotherapy, however, its use has become limited. Recent advances in these modalities have produced beneficial results. In contrast, medications, such as *diuretics*, have been ineffective, showing limited or no benefit. *Meticulous skin care and hygiene* may reduce the incidence of secondary bacterial and fungal infections. If infection does occur, *topical or systemic antibiotics* should be initiated at the first sign of the infection, as infections may lead to further lymphatic injury.

Surgery is reserved for patients refractory to conservative management. *Microsurgical lymphatic-venous anastomoses* have yielded promising results, particularly in repairing traumatic injury. *Excisional surgical therapy* has been performed to reduce limb size and to improve mobility in advanced cases of chronic lymphedema. A notable more recent innovation has been *vascularized lymph node transfer* from one region of the body to another. Reports using this technique are extremely promising.

The scheme proposed here, outlining a two-step conservative therapy and a third-step surgical approach, is for a hypothetical average patient. However, no such individual exists. Preferred therapy varies widely and should be shaped to meet the specific needs of each patient.

Specific Investigations

- Lymphoscintigraphy
- Magnetic resonance imaging (MRI)
- Computed tomography (CT)
- Indocyanine green lymphography

Advances in imaging of lymph flow disorders

Witte CL, Witte MH, Unger EC, Williams WH, Bernas MJ, McNeill GC, et al. Radiographics 2000; 20: 1697–719.

A review illustrating cases in which lymphoscintigraphy, MRI, and CT were used in evaluating and diagnosing primary or secondary lymphedema.

Indocyanine green (ICG) lymphography is superior to lymphoscintigraphy for diagnostic imaging of early lymphedema

of the upper limbs

Mihara M, Hara H, Araki J, Kikuchi K, Narushima M, Yamamoto T, et al. PLoS One 2012; 7: e38182.

Indocyanine green combined with MRI had a higher sensitivity in diagnosing early upper limb lymphedema in comparison to other imaging modalities.

First-Line Therapy

• Complex (or complete) decongestive therapy	C
--	---

Prospective trial of intensive decongestive physiotherapy for upper extremity lymphedema

Karadibak D, Yavuzsen T, Saydam S. J Surg Oncol 2008; 97: 572–7.

This study of 62 women with breast cancer–related lymphedema of an upper extremity demonstrated the effectiveness of CDT by decreasing limb volume and proscribing activity.

Synergic effect of compression therapy and controlled active exercises using a facilitating device in the treatment of arm lymphedema

Godoy Mde F, Pereira MR, Olini AH, de Godoy JM. Int J Med Sci 2012; 9: 280–4.

A randomized controlled trial of 20 women resulted in the reduction of lymphedematous arms from breast cancer treatment by combining compression therapy with controlled exercises using a facilitating device.

Primary lymphedema: clinical features and management in 138 pediatric patients

Schook CC, Mulliken JB, Fishman SJ, Grant FD, Zurakowski D, Greene AK. Plast Reconstr Surg 2011; 127: 2419–31.

Successful management with compression garments without the need for surgical intervention.

Can manual treatment of lymphedema promote metastasis?

Godette K, Mondry TE, Johnstone PA. J Soc Integr Oncol 2006; 4: 8–12.

Contraindications to CDT include hypertension, paralysis, diabetes mellitus, bronchial asthma, acute infections, and congestive heart failure. Malignant disease is also widely considered a contraindication; however, this opinion is not unequivocally supported by current cancer research.

Second-Line Therapy

• Pneumatic compression therapy	B
---------------------------------	----------

Direct evidence of lymphatic function improvement after advanced pneumatic compression device treatment of lymphedema

Adams KE, Rasmussen JC, Darne C, Tan IC, Aldrich MB, Marshall MV, et al. Biomed Opt Express 2010; 1: 114–25.

This study supports the effectiveness of pneumatic compression device treatment by showing lymphatic function improvement in both controlled subjects and breast cancer–related lymphedema patients.

Third-Line Therapies

• Surgery	B
• Low-level laser therapy	A

Microsurgery for lymphedema: clinical research and long term results

Campisi C, Bellini C, Campisi C, Accogli S, Bonioli E, Boccardo F.

Microsurgery 2010; 30: 256–60.

A retrospective study of 1800 subjects undergoing microsurgery for the treatment of peripheral lymphedema resulting in marked improvement in 83% of patients.

Overview of surgical treatments for breast cancer-related lymphedema

Suami H, Chang DW. Plast Reconstr Surg 2010; 126: 1853–63.

A review of surgical procedures for the treatment of breast cancer-related lymphedema and current issues in the management of lymphedema with surgical treatment.

Treatment of postmastectomy lymphedema with laser therapy: double blind placebo control randomized study

Ahmed Omar MT, Abd-El-Gayed Ebid A, El Morsy AM. J Surg Res 2011; 165: 82–90.

Fifty patients were studied, 25 receiving laser and 25 placebo. Low-level laser therapy reduced limb volume and increased shoulder mobility and hand grip strength in 93% of 50 women with breast cancer-related lymphedema.

Indocyanine green lymphographic evidence of surgical efficacy following microsurgical and supermicrosurgical lymphedema reconstructions

Chen WF, Zhao H, Yamamoto T, Hara H, Ding J. J Reconstr Microsurg 2016; 32: 688–98.

Twenty-one patients were noted to have experienced significant improvement with microsurgical reconstruction of lymphedema using newer techniques despite persistence of limb enlargement.

Vascularized lymph node transfer from the thoracodorsal axis for congenital and post filarial lymphedema of the lower limb

Venkatramani H, Kumaran S, Chethan S, Sapapathy SR. J Surg Oncol 2017; 115: 78–83.

Success with an exciting new technique using lymph node transplants from one part of the body to another to correct intractable lymphedema is reported.

A number of similar reports have now been published.

Lymphocytoma cutis

Fiona J. Child

Lymphocytoma cutis (cutaneous lymphoid hyperplasia, cutaneous B-cell pseudolymphoma, Spiegler–Fendt sarcoid) is an entity encompassing a spectrum of benign B-cell lymphoproliferative diseases that share clinical and histopathologic features. Various antigenic stimuli can induce lymphocytoma cutis, but in most cases the cause is not known. It is more common in females, with a female-

to-male ratio of approximately 2:1. Most cases are characterized by localized erythematous, plum-colored nodules and plaques that may be difficult to distinguish from cutaneous B-cell lymphoma. Less frequently the generalized form may present with multiple miliary papules that measure a few millimeters in diameter. Lymphocytoma cutis secondary to *Borrelia* infection is most frequently seen at sites where skin temperature is low, such as the earlobes, nipples, nose, and scrotum.

Management Strategy

A skin biopsy for histopathology and immunohistochemistry is required to confirm the diagnosis, but the distinction between lymphocytoma cutis and cutaneous B-cell lymphoma may be difficult on both clinical and histopathologic evaluation. There are no agreed histologic criteria; however, features that suggest lymphocytoma cutis include an unaffected epidermis, separated by a Grenz zone, below which are well-formed, nonexpanded, reactive germinal centers. The majority of the infiltrate consists of small, round lymphocytes with a B:T cell ratio of <3:1, without cellular atypia, and polytypic expression of kappa and lambda light chains. A further feature is the presence of numerous tangible-body macrophages within the lymphoid follicles. Molecular analysis of the immunoglobulin heavy chain gene has shown that a significant proportion harbor B-cell clones, which suggests that many cases previously thought to be lymphocytoma cutis represent indolent low-grade primary cutaneous B-cell lymphomas (PCBCL). Therefore in cases with a detectable B-cell clone, a careful evaluation to exclude systemic disease (a thorough clinical examination, thoracoabdominopelvic computed tomography [CT] scan, and bone marrow biopsy) is required, with adequate long-term follow-up.

A history of possible stimuli known to cause lymphocytoma cutis should be sought; these include *Borrelia burgdorferi* infection, *Leishmania* infection, trauma, vaccinations, allergy hyposensitization injections, ingestion of drugs, arthropod bites, acupuncture, gold pierced earrings, tattoos, treatment with leeches (*Hirudo medicinalis*), and post-herpes zoster scars, but in most cases the etiology is unknown.

The course of the disease varies but tends to be chronic and indolent, and some lesions may resolve spontaneously without

treatment. There is no therapy of proven value for lymphocytoma cutis, with only anecdotal case reports and small series reported and no clinical trials in the literature.

If a cause can be identified, the causative agent should be removed. If infection with *B. burgdorferi* is suspected, treatment with appropriate *antibiotics* (*amoxicillin* 500–1000 mg three times per day, or *doxycycline* 100 mg two to three times per day for 14–21 days) should be initiated.

Localized disease can be treated by simple *excision* and may respond to *intralesional injection of corticosteroids*, *local irradiation*, or *intralesional interferon- α* . More widespread (generalized) disease is traditionally treated with *oral antimalarials*, most commonly *hydroxychloroquine* (maximum dose 6.5 mg/kg/day); however, lesions may fail to respond to treatment or may recur after cessation of therapy. Other treatment modalities include *subcutaneous interferon- α* and *oral thalidomide*. Effective responses to destructive therapies, including *cryotherapy* and the *argon laser*, have been reported. A subtype of generalized lymphocytoma cutis may be exacerbated by light, and therefore *sun avoidance* and the use of *sun block* are important.

Specific Investigations

- Serology for *B. burgdorferi* (antibodies identified in 50% of patients with borrelial lymphocytoma)
- Skin biopsy for histology, immunophenotype, and immunoglobulin gene analysis
- Patch testing (if a possible contact allergen is suspected)

The spirochetal etiology of lymphadenosis benigna cutis solitaria

Hovmark A, Asbrink E, Olsson I. Acta Derm Venereol 1986; 66: 479–84.

Of 10 patients investigated, four reported a previous tick bite. Positive *Borrelia* serology was found in six of nine patients, and spirochetes were cultured from one of two skin biopsies.

Borrelia burgdorferi-associated lymphocytoma cutis: clinicopathologic, immunophenotypic, and molecular study of

106 cases

Colli C, Leinweber B, Müllegger R, Chott A, Kerl H, Cerroni L. J Cutan Pathol 2004; 31: 232–40.

A total of 106 cases of *B. burgdorferi*-associated lymphocytoma cutis in a region endemic for *Borrelia* infection were studied retrospectively. The most common sites affected were the earlobe, genital area, and nipple (these locations may be due to the predilection of *B. burgdorferi* spirochetes for cooler body sites). In some cases the histopathologic, immunophenotypic, and molecular features were misleading, and it was concluded that integration of all data is necessary to obtain the correct diagnosis.

Borrelial lymphocytoma in adult patients

Maraspin V, Nahtigal Klevišar M, Ruzic-Sabljić E, Lusa L, Strle F. Clin Infect Dis 2016; 63: 914–21.

Cases of borrelial lymphocytoma diagnosed in 144 adults from a single institution were followed for 1 year. Breast and earlobe were the most common sites of involvement, and 72% had concomitant erythema migrans. Ninety percent of patients responded to a course of antibiotics. Those with features of disseminated Lyme borreliosis were most likely to fail treatment, but all responded to retreatment.

Cutaneous lymphoid hyperplasia and cutaneous marginal zone lymphoma: comparison of morphologic and immunophenotypic features

Baldassano MF, Bailey EM, Ferry JA, Harris NL, Duncan LM. Am J Surg Pathol 1999; 23: 88–96.

The histologic and immunophenotypic features of 14 cases of lymphocytoma cutis and 16 cases of cutaneous marginal zone lymphoma were compared.

Differential diagnosis of cutaneous infiltrates of B lymphocytes with follicular growth pattern

Leinweber B, Colli C, Chott A, Kerl H, Cerroni L. Am J Dermatopathol 2004; 26: 4–13.

The histopathologic, immunophenotypic, and molecular features of *B. burgdorferi*-associated lymphocytoma cutis, primary cutaneous follicle center cell lymphoma, and primary cutaneous marginal zone lymphoma were compared. Features that favored lymphocytoma cutis were the presence of tingible-body macrophages, strong

proliferation rate of follicular cells, BCL-2-negative follicular cells, and the absence of monoclonality.

Immunophenotypic and genotypic analysis in cutaneous lymphoid hyperplasias

Hammer E, Sanguenza O, Suwanjindar P, White CR, Brazier R. *J Am Acad Dermatol* 1993; 28: 426–33.

Of 11 patients with histologic and immunophenotypic features of lymphocytoma cutis, clonal rearrangements were detected in two, both of whom subsequently developed B-cell lymphoma.

Polymerase chain reaction analysis of immunoglobulin gene rearrangement analysis in cutaneous lymphoid hyperplasias

Bouloc A, Delfau-Larue M-H, Lenormand B, Meunier F, Wechsler J, Thomine E, et al. *Arch Dermatol* 1999; 135: 168–72.

Twenty-four patients with a diagnosis of lymphocytoma cutis according to clinical, histopathologic, and immunophenotypic criteria underwent polymerase chain reaction (PCR) analysis of the immunoglobulin heavy chain gene using DNA from lesional skin. In one patient, a B-cell clone was detected. In the other 23 a polyclonal result was obtained.

Cutaneous B-cell lymphomas are known to have a relatively high false-negative rate using PCR due to somatic hypermutation, which affects the variable region of the immunoglobulin heavy chain gene and may prevent primer binding. The number of false-negative results may be significantly reduced by using multiple primer sets for different parts of the variable region and for the kappa light chain gene. This paper only used one set of primers, and therefore the detection of only one B-cell clone may be a significant underestimate.

A review of 55 cases of cutaneous lymphoid hyperplasia: reassessment of the histopathologic findings leading to reclassification of 4 lesions as cutaneous marginal zone lymphoma and 19 as pseudolymphomatous folliculitis

Arai E, Shimizu M, Hirose T. *Hum Pathol* 2005; 36: 505–11.

The histopathologic features of 55 cases of cutaneous lymphoid hyperplasia were reassessed. Of these, nine were reclassified as marginal zone lymphoma, distinguished by patchy or diffuse centrocyte-like cells, with plasma cells at the periphery of the infiltrate, monotypic light chain restriction, and a clonal

immunoglobulin heavy chain gene rearrangement.

Clonality assessment of cutaneous B-cell lymphoid proliferations: a comparison of flow cytometry immunophenotyping, molecular studies, and immunohistochemistry/in situ hybridization and review of the literature

Schafernack KT, Variakojis D, Goolsby CL, Tucker RM, Martínez-Escala ME, Smith FA, et al. *Am J Dermatopathol* 2014; 36: 781–95.

Flow cytometry immunophenotyping, which is not routinely applied to the skin, was performed on 73 cutaneous lymphoid infiltrates; B-cell clones were detected in 68% of infiltrates diagnosed as B-cell lymphoma, in contrast to none of the 14 cases of cutaneous lymphoid hyperplasia.

Lymphomatoid contact reaction to gold earrings

Fleming C, Burden D, Fallowfield M, Lever R. *Contact Derm* 1997; 37: 298–9.

A rare entity characterized by nodules at sites of piercing with gold jewelry and the histologic features of lymphocytoma cutis. Patch tests to gold sodium thiosulfate are positive.

Vaccination-induced cutaneous pseudolymphoma

Maubec E, Pinquier L, Viguiier M, Caux F, Amsler E, Aractingi S, et al. *J Am Acad Dermatol* 2005; 52: 623–9.

Nine patients developed cutaneous lymphoid hyperplasia at the site of hepatitis vaccinations. Aluminum deposits were identified in all nine biopsy specimens, and the authors suggest that cutaneous lymphoid hyperplasia is a possible adverse effect of vaccinations that include aluminum oxide as an adjuvant.

Diffuse cutaneous pseudolymphoma due to therapy with medicinal leeches

Altamura D, Calonje E, Liao JL, Rogers M, Verdolini R. *JAMA Dermatol* 2014; 150: 783–4.

Scattered papules and plaques on her back, confirmed histologically as cutaneous lymphoid hyperplasia, developed in a female after application of medicinal leeches for fibromyalgia. The lesions resolved with the application of a topical steroid.

First-Line Therapies

Localized

• Excision	E
• Topical corticosteroids	E
• Intralesional corticosteroids	E
• Oral antibiotics (if positive <i>Borrelia</i> serology)	E
• CO ₂ or Nd:YAG laser (if occurring within a tattoo)	E

Generalized

• Antimalarials	E
• Sun avoidance/sun block (light exacerbated)	E

Treatment of cutaneous pseudolymphoma with hydroxychloroquine

Stoll DM. J Am Acad Dermatol 1983; 8: 696–9.

A case report of a 40-year-old woman with generalized lymphocytoma cutis that cleared with 400 mg hydroxychloroquine daily.

Cutaneous lymphoid hyperplasia (pseudolymphoma) in tattoos: a case series of 7 patients

Kluger N, Vermeulen C, Moguelet P, Cotton H, Koeb MH, Balme B, et al. J Eur Acad Dermatol Venereol 2010; 24: 208–13.

Two of seven patients with cutaneous lymphoid hyperplasia occurring within their tattoos were treated with CO₂ or Nd:YAG laser with improvement.

Second-Line Therapies

Localized

• Superficial radiotherapy	E
• Intralesional interferon- α	E
• Argon laser	E
• Cryotherapy	D
• Topical 0.1% tacrolimus ointment	E
• Intralesional rituximab	E
• Topical photodynamic therapy	E

Generalized

• Subcutaneous interferon- α_{2b}	E
• Thalidomide	E

Cutaneous lymphoid hyperplasia: results of radiation therapy

Olson LE, Wilson JF, Cox JD. Radiology 1985; 155: 507–9.

Four cases of lymphocytoma cutis were treated with radiation therapy. Over a follow-up period of 8 months to 7 years there were no recurrences.

Local orthovolt radiotherapy in primary cutaneous B-cell lymphoma

Pimpinelli N, Vallecchi C. Skin Cancer 1999; 14: 219–24.

Data from 115 patients with PCBCL produced a 98.2% complete remission rate and a median disease-free period of 55 months; recurrences were mostly limited to the skin. In view of the difficulties

in distinguishing between PCBCL and lymphocytoma cutis, many groups have used superficial radiotherapy in cases of lymphocytoma cutis, although evidence remains anecdotal.

In our experience these cases are relatively radioresistant compared with PCBCL.

Treatment of cutaneous pseudolymphoma with interferon alfa-2b

Tomar S, Stoll HL, Grassi MA, Cheney R. J Am Acad Dermatol 2009; 60: 172–4.

One patient with multiple nodules and plaques was treated with intralesional interferon- α_{2b} (1 MU in 1 mL saline) every 2 weeks for a total of 5 weeks with complete resolution of all lesions except for one that was subsequently excised.

Role of the argon laser in treatment of lymphocytoma cutis

Wheeland RG, Kantor GR, Bailin PL, Bergfeld WF. J Am Acad Dermatol 1986; 14: 267–72.

The argon laser improved cosmetic appearance and alleviated symptoms of lymphocytoma cutis, but failed to provide complete histologic clearing in a young man who had failed to respond adequately to initial therapy with hydroxychloroquine.

Lymphocytoma cutis: a series of five patients successfully treated with cryosurgery

Kuflik AS, Schwartz RA. J Am Acad Dermatol 1992; 26: 449–52.

Five patients with lymphocytoma cutis underwent therapy with liquid nitrogen to individual lesions using a single cycle of 15 to 20 seconds per lesion, with complete clinical resolution of all lesions treated within 3 to 6 weeks.

Spiegler–Fendt type lymphocytoma cutis: a case report of two patients successfully treated with interferon alpha-2b

Hervonen K, Lehtinen T, Vaalasti A. Acta Derm Venereol 1999; 79: 241–2.

Two men who had generalized lymphocytoma cutis and had failed to respond to other therapies were treated with subcutaneous interferon- α_{2b} 2.5 MU three times per week, with complete resolution of all lesions by 3 months. However, lesions recurred in both men between 6 and 23 months after the completion of treatment.

Treatment of cutaneous lymphoid hyperplasia with thalidomide: report of two cases

Benchikhi H, Bodemer C, Fraitag S, Wechsler J, Delfau-Larue M-H, Gounod N, et al. *J Am Acad Dermatol* 1999; 40: 1005–7.

Two cases of lymphocytoma cutis involving the nose that showed complete regression after treatment with thalidomide for 3 months at a dose of 100 mg once daily for 2 months and 50 mg once daily for the third month. There was no recurrence at 36 and 31 months follow-up, respectively.

Disseminated cutaneous lymphoid hyperplasia of 12 years' duration triggered by vaccination

Pham-Ledard A, Vergier B, Doutre MS, Beylot-Barry M. *Dermatology* 2010; 220: 176–9.

A 17-year old-girl with long-standing hepatitis B vaccination–induced cutaneous lymphoid hyperplasia was treated with oral thalidomide with a complete clinical response.

Lymphocytoma cutis treated with topical tacrolimus

El-Dars LD, Statham BN, Blackford S, Williams N. *Clin Exp Dermatol* 2005; 30: 305–7.

Two cases of lymphocytoma cutis affecting the face were treated with topical tacrolimus 0.1% twice daily. In both cases the lesions completely resolved after 8 months, application.

Treatment of cutaneous lymphoid hyperplasia with the monoclonal anti-CD20 antibody rituximab

Martin SJ, Duvic M. *Clin Lymphoma Myeloma Leuk* 2011; 11: 286–8.

One case of lymphocytoma cutis was treated with intralesional rituximab with notable clinical improvement. Persistent and recurrent erythematous areas were subsequently treated with topical tacrolimus with further improvement.

Successful treatment of lymphadenosis benigna cutis with topical photodynamic therapy with delta-aminolevulinic acid

Takeda H, Kaneko T, Harada K, Matsuzaki Y, Nakano H, Hanada K. *Dermatology* 2005; 211: 264–6.

Two females were treated with five treatments of topical δ -aminolevulinic acid photodynamic therapy (ALA-PDT) with dramatic clinical and histopathologic improvement

Lymphogranuloma venereum

Frederick A. Pereira

Classic lymphogranuloma venereum (LGV) is an uncommon, sexually transmitted infection (STI) occurring in the tropics. It is characterized by three stages of disease: (1) transient genital ulceration; (2) painful, suppurative inguinal lymphadenopathy; and (3) fibrosis, lymphatic obstruction, and genital elephantiasis. A new LGV syndrome has emerged in the industrialized world among men

who have sex with men (MSM). The clinical picture consists of proctitis with associated tenesmus, mucopurulent discharge, abdominal pain, and perianal ulceration. Lymphadenopathy is not a prominent feature of the proctitis syndrome. Asymptomatic infection can occur in all forms of LGV. LGV is a systemic disease of lymphoid tissue caused by serovars L1, L2, and L3 of *Chlamydia trachomatis*. It can be associated with extragenital manifestations such as erythema nodosum, myalgia, reactive arthritis, fever, fatigue, and weight loss.

Management Strategy

The long-term sequelae of untreated LGV are horrific, and treatment should be started immediately on the basis of clinical suspicion, epidemiologic information, and exclusion of other diagnoses. Treatment should *not* be delayed pending positive laboratory confirmation. Nucleic acid amplification testing (NAAT) is the method of choice to detect *C. trachomatis*. Material can be obtained from an ulcer base, rectal mucosa, or bubo aspirate. That material is then tested with a screening NAAT to detect chlamydia. If *C. trachomatis* is detected, a second NAAT is used to identify the specific serovar. If NAAT testing is not available, a single complement fixation test in titer greater than 1:64 or a fourfold rise in titer over a few weeks is strongly suggestive of LGV.

The treatment of choice is *doxycycline* 100 mg twice daily for 3 weeks. *Fluoroquinolones* and *tetracyclines* are contraindicated in pregnant and lactating women. These women should be treated with *erythromycin* 500 mg four times daily for 3 weeks. Children with LGV should be treated with erythromycin. *Azithromycin* 1 g once a week for 3 weeks has been used successfully as an alternative to erythromycin. Moxifloxacin has antichlamydial activity, but there are only anecdotal reports of its use in LGV. HIV-positive patients are treated with the same regimens; however, these patients may require prolonged treatment, and they must be closely monitored for treatment failure and relapse. Fluctuant buboes should be drained by needle aspiration through normal skin at the superior pole. Buboes should not be incised because of danger of sinus formation.

All patients with LGV should be tested for other STIs and bloodborne diseases, particularly HIV and hepatitis B and C. Intensive and repeated safe-sex counseling is necessary because most patients continue to engage in high-risk behaviors. Sex partners

should be evaluated, tested for infection, and then presumptively treated with azithromycin 1 g orally or doxycycline 100 mg twice a day for 7 days.

Specific Investigations

- NAAT
- Chlamydial serology

Lymphogranuloma venereum 2015: clinical presentation, diagnosis, and treatment

Stoner BP, Cohen SE. Clin Infect Dis 2015; 61(Suppl 8): S865–73.

Proctitis and proctocolitis are now the most common clinical manifestations of LGV. The classic inguinal presentation with buboes is becoming increasingly uncommon.

Lymphogranuloma venereum among men who have sex with men. An epidemiologic and clinical review

De Vrieze NH, de Vreis HJ. Expert Rev Anti Infect Ther 2014; 12: 697–704.

Approximately 25% of infections are asymptomatic. MSM who have had receptive anal intercourse in the past 6 months should be screened. Asymptomatic carriers are a reservoir of infection, and these persons should be treated.

2013 European guideline on the management of lymphogranuloma venereum

De Vries HJ, Zingoni A, Kreuter A, Moi H, White JA. J Eur Acad Dermatol Venereol 2015; 29: 1–6.

After resolution of signs and symptoms after a full 21 days of treatment, a microbiological “test of cure” is not considered necessary. Patients should be tested for other STIs and hepatitis B and C. In addition, they should be warned of the risks of unprotected sex and mucosally traumatic sexual practices such as enemas and use of sexual toys.

Lymphogranuloma venereum presenting as perianal ulceration: an emerging clinical presentation?

Singhrao T, Higham E, French P. Sex Transm Infect 2011; 87: 123–4.

LGV, along with herpes simplex, chancroid, and syphilis, must be included in the differential diagnosis of anal ulcers, particularly in MSM. Herpes simplex remains the most common cause.

Lymphogranuloma venereum

Herring A, Richens J. Sex Transm Infect 2006; 82: 23–5.

The laboratory diagnosis of LGV consists of detection of *C. trachomatis*-specific DNA followed by genotyping to identify serovars L1, L2, or L3. Culture of chlamydiae is technically difficult, and few laboratories have the facilities to do this. Complement fixation studies can be useful for diagnosis. High or rising titers in a symptomatic patient are suggestive of LGV.

The association between lymphogranuloma venereum and HIV among men who have sex with men: systematic review and meta-analysis

Rönn MM, Ward H. BMC Infect Dis 2011; 11: 70.

In 13 studies the prevalence of HIV among MSM with LGV ranged from 67% to 100%. HIV + MSM are disproportionately affected by LGV.

Persistent high-risk sexual behavior in men who have sex with men after symptomatic lymphogranuloma venereum proctitis

Van den Bos RR, van der Meijden WI. Int J STD AIDS 2007; 18: 715–6.

After treatment of LGV proctitis, 17 of 26 patients (65%) were subsequently treated for another STI within 3 years. Health education and counseling efforts must be intensified because patients continue to engage in high-risk sexual activities.

First-Line Therapy

• Doxycycline 100 mg orally twice daily for 21 days	B
---	----------

Centers for Disease Control and Prevention. Sexually transmitted disease treatment guidelines, 2015

Workowski KA, Bolan GA. MMWR Recomm Rep 2015; 64: 1–137.

Second-Line Therapies

• Erythromycin base 500 mg orally four times daily for 21 days	B
• Azithromycin 1.0 g orally once weekly for 3 weeks	C
• Moxifloxacin 400 mg daily for 10 days	E
• Aspiration of buboes	B

Treatment of lymphogranuloma venereum

McLean CA, Stoner BP, Workowski KA. Clin Infect Dis 2007; 44: 147–52.

Doxycycline 100 mg twice daily for 3 weeks is recommended as first-line treatment for LGV. Azithromycin 1.0 g orally once weekly for 3 weeks appears to be effective against LGV. Erythromycin base 500 mg four times a day orally is the preferred treatment for pregnant women with LGV.

Doxycycline failure in lymphogranuloma venereum

Méchai F, de Barbayrac B, Aoun O, Mérens A, Umberto P, Rapp C. Sex Transm Infect 2010; 86: 278–9.

The authors report a patient with LGV proctitis who failed a full 3-week course of doxycycline. The patient achieved rapid clinical cure with a 10-day course of moxifloxacin 400 mg daily. Failure of doxycycline is unusual.

An audit on the management of lymphogranuloma venereum in a sexual health clinic in London, UK

Hill SC, Hodson L, Smith A. Int J STD AIDS 2010; 21: 772–6.

Fifty-five patients were treated with doxycycline, and seven patients were treated with azithromycin 1 g per week for 3 weeks. All patients treated with azithromycin achieved clinical cure, and microbiological cure was proven in six. Half of the treated patients returned for follow-up within 3 months; a notable proportion tested positive for newly acquired STIs. Patients continue to engage in high-risk behaviors after treatment, and safe-sex counseling efforts need to be intensified.

Lymphogranuloma venereum

Becker LE. Int J Dermatol 1976; 15: 26–33.

Incision and drainage of buboes is not recommended. Fluctuant buboes should be aspirated at the superior pole through normal skin with a large-bore needle.

Lymphomatoid papulosis

Rachel S. Klein, Elisha Singer, Jacqueline M. Junkins-Hopkins, Carmela C. Vittorio, Alain H. Rook, and Ellen J. Kim

Lymphomatoid papulosis (LyP) is a distinct subset of CD30+ lymphoproliferative disorders in the World Health Organization/European Organization for the Research and Treatment of Cancer (WHO/EORTC) classification of cutaneous lymphomas, defined histologically by a variable infiltrate of CD30+ lymphocytes, in conjunction with the clinical presentation of crops of recurrent, self-

healing papulonodules. Patients may present with very few or with multiple lesions, which may evolve into a crusted or necrotic stage, which often heal with a scar. Less common presentations include regional, isolated acral, and oral disease. Itching can occur. LyP affects adults and children as young as 11 months of age and may persist for years to decades. Approximately 5% to 25% of patients with LyP may present with or develop a lymphoproliferative malignancy, such as mycosis fungoides (MF – cutaneous T-cell lymphoma, CTCL), anaplastic large cell lymphoma (ALCL), and Hodgkin or non-Hodgkin lymphomas. There may also be a slight risk of developing a nonhematologic neoplasm. The same clone has been documented in some patients with LyP and the associated lymphoma (including MF and ALCL), supporting the concept that LyP lies within the spectrum of CTCL. Clinical and histologic overlap may also be seen with LyP and arthropod bites, pityriasis lichenoides, and folliculitis.

Management Strategy

Most important, the management of LyP begins with understanding the natural history of the disease. LyP is defined as a recurrent, self-healing (remission of every individual lesion), papulonodular eruption, with histology suggesting CTCL. There are six histologic variants, including type A (wedge-shaped infiltrate containing eosinophils and histiocytes), type B (epidermotropism, resembles MF), type C (cohesive sheets of CD30+ cells, resembles ALCL), type D (CD8/CD30+, resembles primary cutaneous aggressive epidermotropic CD8+ cytotoxic T-cell lymphoma), type E (CD30+ with angioinvasion), and type F (CD30+, follicular). Long-term survival does not appear to vary among the histologic subtypes, but associated lymphomas may be seen more commonly with subtypes B and C. A minor subset of LyP patients may have chromosomal rearrangements involving the DUSP22-IRF4 (dual specificity protein phosphatase 22/interferon regulatory factor 4) locus on 6p25.3, which has been observed in some cutaneous ALCL patients.

Clinical evaluation should include a complete history assessing for atypical features, including previous lymphoid neoplasms, constitutional symptoms, lymphadenopathy, or laboratory abnormalities on complete blood counts, blood chemistry, and lactate dehydrogenase. Patients with abnormal findings should undergo computed tomography (CT) or positron emission tomography

(PET)/CT scanning to exclude a systemic lymphoma. Distinguishing LyP from primary cutaneous ALCL is important, although this may be difficult because of clinical and histologic overlap, including spontaneous regression.

Persistent lesions greater than 2 to 3 cm in diameter favor primary cutaneous ALCL; however, some patients do not fit well into either category. Such “borderline” cases have similar biological behavior to LyP and can be managed as such.

Treatment of LyP should be tailored to the disease burden, because treatment has not been proven to alter the natural course of LyP, nor does treatment prevent the development of associated lymphomas. Treatment should be reserved for symptomatic or cosmetically bothersome cases. First-line therapies include *topical corticosteroids*, *low-dose methotrexate*, and *phototherapy*. A response may be seen within the first few weeks of treatment, including the development of fewer lesions, faster resolution of individual lesions, and occasionally induction of remission. Large or borderline lesions can be treated with *local radiotherapy* or *excision*. Therapies that are beneficial in MF may also be used, including topicals such as *carmustine* (BCNU), *mechlorethamine* (nitrogen mustard), *bexarotene*, and *imiquimod* cream 5%. Systemic biologic agents such as *interferon-α* and the retinoid X receptor agonist *bexarotene* are also effective for suppression of lesions. In severe cases, the anti-CD30 antibody, *brentuximab vedotin*, is effective; however, this must be balanced by the risks of peripheral neuropathy, neutropenia, and rarely, progressive multifocal leukoencephalopathy (PML). Multiagent chemotherapy is not indicated, despite histologic features that may suggest ALCL. LyP can recur for decades, requiring careful consideration of treatment side effects and continued monitoring for the development of lymphoma.

Specific Investigations

- Biopsy and histologic review to confirm the diagnosis
- Exclusion of constitutional (“B”) symptoms, clinical hepatosplenomegaly/lymphadenopathy, or laboratory abnormalities
- Ongoing surveillance for a lymphoproliferative neoplasm

EORTC, ISCL, and USCLC consensus recommendations for the

treatment of primary cutaneous CD30-positive lymphoproliferative disorders: lymphomatoid papulosis and primary cutaneous anaplastic large-cell lymphoma

Kempf W, Pfaltz K, Vermeer M, Cozzio A, Ortiz-Romero P, Bagot M, et al. Blood 2011; 118: 4024–35.

These consensus guidelines give recommendations for the management of the spectrum of CD30+ cutaneous lymphoproliferative disease. Typical LyP does not require staging procedures if there is a normal physical examination and review of systems. Long-term follow-up is required for all subtypes.

Lymphomatoid papulosis. Reappraisal of clinicopathologic presentation and classification into subtypes A, B, and C

El Shabrawi-Caelen L, Kerl H, Cerroni L. Arch Dermatol 2004; 140: 441–7.

A retrospective review of 85 patients with LyP documented histologic overlap between subtypes A, B, and C and between type B and MF. Eight percent of patients had more than one histologic subtype of LyP. The authors also stress the tight overlap with LyP and CD30 lymphoma. A variety of clinicohistopathologic presentations of LyP, including those with histology showing follicular mucinosis, syringotropism, vesicle formation, MF-like bandlike infiltrates, and associated keratoacanthoma, are discussed.

A variant of lymphomatoid papulosis simulating primary cutaneous aggressive epidermotropic CD8+ cytotoxic T-cell lymphoma. Description of 9 cases

Saggini A, Gulia A, Argenyi Z, Fink-Puches R, Lissia A, Magaña M, et al. Am J Surg Pathol 2010; 34: 1168–75.

A variant of LyP, termed *LyP type D*, is described in nine patients with clinical aspects of LyP but with histopathologic features resembling primary cutaneous aggressive epidermotropic CD8+ cytotoxic lymphoma. The histology of LyP type D is of medium sized CD8+ CD30+ pleomorphic cells with prominent, pagetoid reticulis-like epidermotropism. None of the patients developed a lymphoproliferative malignancy during a mean follow-up of 84 months.

Accurate clinicopathologic correlation is necessary to avoid misdiagnosing LyP type D patients.

Angioinvasive lymphomatoid papulosis: a new variant simulating aggressive lymphomas

Kempf W, Kazakov DV, Schärer L, Rütten A, Mentzel T, Paredes BE, et al. *Am J Surg Pathol* 2013; 37: 1–13.

Another variant of LyP is retrospectively described in 16 patients with oligolesional papules that ulcerated, with histology showing CD30+, often CD8+ angioinvasive T cells, termed *type E LyP*. Such histology can overlap with cytotoxic cutaneous lymphomas, but none of the patients developed extracutaneous disease.

Follicular lymphomatoid papulosis revisited: a study of 11 cases, with new histopathological findings

Kempf W, Kazakov DV, Baumgartner HP, Kutzner H. *J Am Acad Dermatol* 2013; 68: 809–16.

Follicular LyP is a variant of LyP with involvement of hair follicles, mostly in the form of perifollicular infiltrate with variable degrees of folliculotropism. Other changes, including hyperplasia of the follicular epithelium, rupture of hair follicle, and follicular mucinosis, are less common. Rarely, intrafollicular pustules can be seen in the follicular epithelium; such lesions manifest clinically as pustules.

Some propose that follicular LyP should be termed LyP type F; others propose it is a subtype of types A and C.

Primary and secondary cutaneous CD30+ lymphoproliferative disorders: a report from the Dutch Cutaneous Lymphoma Group on the long-term follow-up data of 219 patients and guidelines for diagnosis and treatment

Bekkenk MW, Geelen FAMJ, van Voorst Vader PC, Heule F, Geerts ML, van Vloten WA, et al. *Blood* 2000; 95: 3653–61.

Guidelines are proposed for the diagnosis and treatment of patients with CD30+ lymphoproliferative disorders based on long-term follow-up of 219 patients, 118 of whom had LyP (4% had tumors). Fifty-two of 118 patients received no treatment or topical corticosteroids. The remainder received a variety of standard treatments, none of which was associated with complete, sustained remission. Staging of patients with type C LyP failed to reveal extracutaneous disease. Nineteen percent developed an associated lymphoma. Induction of remission of the secondary lymphoma had no effect on the natural course of LyP. The calculated risk for extracutaneous disease was 4% at 10 years.

Lymphomatoid papulosis: treatment response and associated lymphomas in a study of 180 patients

Wieser I, Oh CW, Talpur R, Duvic M. J Am Acad Dermatol 2016; 74: 59–67.

In this retrospective chart review of 180 patients diagnosed with LyP between 1995 and 2015 at a specialty clinic, 47.2% of patients had histologic subtype A, 17.2% type B, 22.8% type C, 7.8% type D, 0.6% type E, and 4.4% mixed subtype. One hundred fourteen other lymphomas were observed in 93 patients (51.6% of cohort), with the most common being MF (61.4%) and ALCL (26.3%). Risk factors for development of lymphoma included male sex and histologic subtypes B and C. Number of lesions and symptom severity were not associated with lymphoma development. Patients with type D were less likely to have lymphomas. The presence of T-cell clonality was not associated with increased lymphoma risk. Treatment provided symptomatic relief but did not prevent progression to lymphoma.

The overall higher association (40%) with lymphoma compared with other studies may represent a referral bias.

CD30+ cutaneous lymphoproliferative disorders: the Stanford experience in lymphomatoid papulosis and primary cutaneous anaplastic large cell lymphoma

Liu HL, Hoppe RT, Kohler S, Harvell JD, Reddy S, Kim YH. J Am Acad Dermatol 2003; 49: 1049–58.

In 19 of 31 cases with LyP, a higher than previously reported associated coexisting hematolymphoid malignancy (61% with one or more) was noted. Most had MF, which occurred before, during, or after the diagnosis of LyP. Some had two hematolymphoid malignancies. Three progressed to ALCL, with an interval ranging from 77 to 152 months. The overall 5- and 10-year survival of patients with LyP was 100% and 92%, respectively, and none died of LyP. Those with ALCL had a favorable course. LyP subtype did not predict the risk of associated malignancy.

The higher association with malignancy may represent selection bias.

Lymphomatoid papulosis in children: a series of 25 cases

Miquel J, Fraitag S, Hamel-Taillac D, Molina T, Brousse N, de Prost Y, et al. Br J Dermatol 2014; 171: 1138–46.

This is a retrospective analysis of lymphomatoid papulosis in 25 children up to 15 years of age (15 male, 10 female; median age 7.5

years) diagnosed with LyP (82% were type A, remainder type C). Marked eosinophilic infiltrate was common (44%). No associated lymphomas were observed during median follow-up of 10 years. Pityriasis lichenoides chronica (PLC) was observed in 36% of patients and atopic dermatitis in 28%.

In children, PLC may be a predisposing factor for LyP.

Lymphomatoid papulosis in children: a retrospective cohort study of 35 cases

Nijsten T, Curiel-Lewandrowski C, Kadin ME. Arch Dermatol 2004; 140: 306–12.

In a retrospective cohort analysis of 35 patients diagnosed with LyP during childhood (less than 18 years old) followed over a mean duration of 9 years, 3 patients (9%) developed a malignant non-Hodgkin lymphoma. No clinical risk factors were identified. Patients with childhood LyP were also significantly more likely to have atopy.

Children with LyP have an approximate 10% risk of developing a hematologic malignancy during their lives and thus require careful lifelong monitoring.

Single cell analysis of CD30+ cells in lymphomatoid papulosis demonstrates a common clonal T-cell origin

Steinhoff M, Hummel M, Anagnostopoulos I, Kaudewitz P, Seitz V, Assaf C, et al. Blood 2002; 100: 578–84.

The large CD30+ cells in LyP type A represent a single clone within each individual case, whereas the majority of CD30– cells are polyclonal. The identical T-cell clone can be identified in separate skin lesions and at different time points, demonstrating the persistence of the T-cell clone in LyP.

Assessment for clonality will not help differentiate borderline cases of LyP from ALCL or MF.

Lymphomatoid papulosis associated with mycosis fungoides: a study of 21 patients including analyses for clonality

Zackheim H, Jones C, LeBoit PE, Kashani-Sabet M, McCalmont TH, Zehnder J. J Am Acad Dermatol 2003; 49: 620–3.

Of 54 patients with LyP, 39% had MF. LyP preceded (67%), followed (19%), or was concurrent with (14%) a diagnosis of MF, and 95% had type A LyP. Of those checked (7 patients) 100% had an identical clone in MF and LyP lesions.

Large cell transformation mimicking regional lymphomatoid papulosis in a patient with mycosis fungoides

Nakahigashi K, Ishida Y, Matsumura Y, Kore-eda S, Ohmori K, Fujimoto M, et al. J Dermatol 2008; 35: 283–8.

The authors report a 57-year-old man with stage III MF who developed a regional eruption of either transformed MF or type C LyP on his chest. Spontaneous resolution supported the diagnosis of LyP.

The importance of differentiating LyP from large cell transformation of MF is stressed. In contrast to LyP, which is associated with a better prognosis, in patients with MF, those with large cell transformation have a worse prognosis.

First-Line Therapies

• Therapy not required	B
• PUVA (Psoralen ultraviolet A) phototherapy	B
• Low-dose methotrexate	B
• Topical corticosteroids	E

Practical management of CD30+ lymphoproliferative disorders

Hughey LC. Dermatol Clin 2015; 33: 819–33.

This recent review discusses current therapies for symptomatic LyP. Given the excellent long-term prognosis, it may be reasonable to simply monitor off therapy. The remaining specific treatment options are discussed in further detail.

PUVA-treatment in lymphomatoid papulosis

Wantzin GL, Thompsen K. Br J Dermatol 1982; 107: 687–90.

Five patients with LyP, including one patient with tumors, were treated with PUVA (51–124 J/cm² for classic LyP and 481 J/cm² for tumors). There was a reduction in the number of lesions and shortening of the life cycle of each individual lesion to 1 week from 3 to 6 weeks. Remission was achieved in one patient.

Methotrexate is effective therapy for lymphomatoid papulosis and other primary cutaneous CD30+ lymphoproliferative disorders

Vonderheid EC, Sajjadian A, Kadin ME. J Am Acad Dermatol 1996; 34: 470–81.

A 20-year experience of methotrexate therapy in 45 patients with LyP, CD30+ lymphoma, and borderline cases is reviewed. Patients responded within 4 weeks (15–20 mg weekly). Maintenance doses were given at 10- to 14-day intervals (range 7–28 days); 29% had concomitant MF, requiring other therapies (mechlorethamine hydrochloride, carmustine, standard UV (ultraviolet) therapy, and PUVA), which offered some additional benefit, but the relative effectiveness was less than with methotrexate. LyP and CD30+ lymphoma responded similarly. Three patients had diminished responsiveness, suggesting resistance to methotrexate. Severe exacerbations occurred upon abrupt drug discontinuation.

This is considered first-line therapy for symptomatic disease, with disease control typical but remission off drug uncommon.

Lymphomatoid papulosis: successful weekly pulse superpotent topical corticosteroid therapy in three pediatric patients

Paul MA, Krowchuk DP, Hitchcock MG, Jorizzo JL. Pediatr Dermatol 1996; 13: 501–6.

Three children with LyP were treated with halobetasol or clobetasol propionate twice daily for 2 to 3 weeks, followed by weekly pulsed application, resulting in complete resolution of nearly all cutaneous lesions. Adjuvant intralesional triamcinolone was used for three ulcerated lesions.

Although this modality is unlikely to alter the disease course, it is a reasonable treatment approach because it has a relatively low complication profile.

Second-Line Therapies

• Topical mechlorethamine (nitrogen mustard)	B
• Topical carmustine	C
• Topical bexarotene	C

Long-term efficacy, curative potential, and carcinogenicity of topical mechlorethamine chemotherapy in cutaneous T cell lymphoma

Vonderheid EC, Tan ET, Kantor AF, Shrager L, Micaily B, Van Scott EJ. J Am Acad Dermatol 1989; 20: 416–28.

Seven patients with LyP and 17 with concomitant LyP and MF were treated with 10 to 20 mg of mechlorethamine dissolved in 40 to 60 mL water and applied once daily to the entire skin surface except for the genitalia, until at least 2 weeks after complete clearance of lesions. Four of the seven with LyP achieved a complete response, with one lasting for more than 8 years of follow-up. A slightly increased risk of squamous and basal cell carcinomas, Hodgkin disease, and colon cancer was noted.

A common side effect of mechlorethamine therapy is an allergic hypersensitivity reaction, which may occur less frequently when mechlorethamine is prepared in an ointment base.

Topical carmustine therapy for lymphomatoid papulosis

Zacheim HS, Epstein EH, Crain WR. Arch Dermatol 1985; 121: 1410–4.

Seven patients with LyP were treated with once-daily total skin applications of topical carmustine. Total doses ranged from 280 to 1180 mg. Local treatment of individual lesions after the total skin course included twice-daily application of 2 mg/mL or 4 mg/mL 95% ethanol. All patients had a rapid reduction in the number and size of lesions. Lesions cleared faster and did not scar with maintenance therapy, but remission was not seen. Rare persistent telangiectases were noted.

Third-Line Therapies

• Oral bexarotene	C
• Recombinant interferon	C
• Excimer laser	E
• Radiotherapy	E
• Topical methotrexate	E
• Imiquimod cream	E
• Brentuximab vedotin	B

Bexarotene is a new treatment option for lymphomatoid papulosis

Krathen RA, Ward S, Duvic M. *Dermatology* 2003; 206: 142–7.

Oral bexarotene, started at 300 mg daily, was associated with more rapid disappearance, less necrosis, and a reduction in new lesions. One of three patients had a complete response. Topical bexarotene used in patients with less than 10% body surface area involved had a similar benefit.

Oral bexarotene is often used in conjunction with levothyroxine and lipid-lowering agents because of frequently seen central hypothyroidism and hyperlipidemia.

Therapeutic use of interferon-alpha for lymphomatoid papulosis

Schmuth M, Topar G, Illersperger B, Kowald E, Fritsch PO, Sepp NT. *Cancer* 2000; 89: 1603–10.

Five patients were treated with subcutaneous interferon- α , 3 to 15 million IU (international units) three times per week. Three were treated for 12 to 13 months, and each achieved a complete response

that was durable for at least 1 year after discontinuation of therapy. Two were treated for 5 to 7 months: one had a partial response and one had complete response; however, neither was durable after discontinuation of therapy. Only one of six controls achieved spontaneous remission.

308-nm excimer laser for the treatment of lymphomatoid papulosis and stage IA mycosis fungoides

Kontos AP, Kerr HA, Malick F, Fivenson DP, Lim HW, Wong HK. Photodermatol Photoimmunol Photomed 2006; 22: 168–71.

A patient with LyP who had a failed response to PUVA and methotrexate was treated with the 308-nm excimer pulse laser, 13 treatments three times per week, with a maximum fluence of 500 mJ/cm². This resulted in 75% clearance, with minimal recurrence and postinflammatory hyperpigmentation.

This handheld device allows delivery of higher fluences, with a diminished risk of carcinogenesis.

Persistent agmination of lymphomatoid papulosis: an equivalent of limited plaque mycosis fungoides type of cutaneous T-cell lymphoma

Heald P, Subtil A, Breneman D, Wilson LD. J Am Acad Dermatol 2007; 57: 1005–11.

Seven cases of regional LyP were treated as if they were localized MF, with local radiotherapy, resulting in long-standing remissions. The radiation doses ranged from 30 to 46 Gy in fractionated doses. One patient also had topical bexarotene and localized electron beam therapy. At follow-up (2–6 years), six of the seven had no recurrences. One patient with recurrence subsequently achieved complete remission with interferon- α and PUVA.

Treatment of regional LyP with localized radiation therapy as if it were MF may offer prolonged remission of LyP, but, as demonstrated, these patients may still develop an associated lymphoma. Long-term follow-up is critical.

Treatment of lymphomatoid papulosis with imiquimod 5% cream

Hughes PH. J Am Acad Dermatol 2006; 54: 546–7.

A 13-year-old boy with LyP was reported to have a complete response within 2 weeks with lesional application of imiquimod 5% cream three times per week.

Patients' responses to imiquimod are variable, and patients should be warned of possible inflammation. The usefulness of imiquimod is limited by its cost.

Results of a phase II trial of brentuximab vedotin for CD30+ cutaneous T-cell lymphoma and lymphomatoid papulosis

Duvic M, Tetzlaff MT, Gangar P, Clos AL, Sui D, Talpur R. J Clin Oncol 2015; 33: 3759–65.

Brentuximab vedotin is a monoclonal antibody to CD30 that is conjugated to the tubulin toxin monomethyl auristatin E, that was initially approved by the Food and Drug Administration (FDA) for refractory Hodgkin lymphoma and systemic ALCL. This single-center, open-label phase II study demonstrated efficacy in CD30-expressing CTCLs (primary cutaneous ALCL, LyP, or transformed MF/Sézary syndrome). At a dose of 1.8 mg/kg given intravenously every 3 weeks, overall response rate in 48 patients was 73% (35% achieved complete response). All patients with LyP ($n = 9$) and primary cutaneous ALCL ($n = 2$) responded; time to response was 3 weeks (range, 3–9 weeks), and median duration of response was 26 weeks (range, 6–44 weeks). The most common adverse event was peripheral neuropathy (65% of patients, grade 1 or 2), which can persist.

Brentuximab vedotin has considerable efficacy in a variety of CD30-expressing CTCLs with reasonable side effect profile. However, peripheral neuropathy is common, and though not seen in this study, the FDA issued a black box warning on brentuximab vedotin due to the development of PML (in five patients reported thus far) treated with it. Of note, these patients were heavily pretreated with immunosuppressive medications, which is generally not the case in LyP patients. Given the overall favorable prognosis of LyP, brentuximab vedotin should be reserved for only severe refractory LyP cases.

Malignant atrophic papulosis

Noah Scheinfeld

Malignant atrophic papulosis (MAP), also known as *Degos disease* (DD), is a disorder characterized by occlusive vasculopathy; it possesses purely cutaneous and systemic variants. They are starkly divided by their prognosis, with purely cutaneous DD being wholly benign in course, and systemic DD usually being fatal within a few years of onset. Cutaneous DD can precede the development of

systemic DD, and no factor has yet been defined that will predict those with cutaneous DD who will go on to develop systemic DD. The cause of death in systemic DD is related to perforation of blood vessels, bleeding, and intestinal perforation. Systemic MAP can involve the nervous, ophthalmologic, gastrointestinal (GI), cardiothoracic, and hepatorenal systems

Management Strategy

It is likely that the purely cutaneous type of DD is underdiagnosed as it is banal and benign. The disease is more commonly reported in men and young adults, but this may simply be sampling error.

Cutaneous and systemic DD have similar cutaneous eruptions. In the skin, DD occurs as erythematous, pink or red papules (2–15 mm), which evolve into scars with central, porcelain-white atrophic centers. The papules of MAP usually have a peripheral telangiectatic rim and can be domed or atrophic. The papules can have central crusts. Urticaria, ulceropustular, and/or gummalike nodules can manifest. All areas of the body, with the exception of the face, can be involved.

Viruslike inclusions, observable with an electron microscope, are frequently present in the endothelial cells and fibroblasts of patients with DD. C3 deposits are sometimes noted. There can be intracytoplasmic cylinders in the histiocytes.

Pathologically, the tissue affected by DD reveals an occlusive arteriopathy involving small-caliber vessels resulting in tissue infarction. The bland appearance of MAP vasculopathy (or an endovasculitis) on histologic examination does not equate with the serious nature of systemic DD.

No specific laboratory test can be used to diagnose DD. Cases of DD can manifest antiphospholipid antibodies and antinuclear antibodies, but these seem to be correlative rather than causative antibodies. Some reports note increased plasma fibrinogen levels, increased platelet aggregations, and a decrease of local and systemic fibrinolytic activity. There are cases of systemic lupus erythematosus and other collagen vascular diseases that display DD-like atrophic porcelain-white papules; however, these cases likely do not represent cases of DD.

Histopathology shows a wedge-shaped degeneration of collagen with a prominent interface reaction with squamatization of the dermoepidermal junction, melanin incontinence, and epidermal

atrophy.

The role of imaging and laboratory investigations is to establish if systemic MAP is present so that treatment with newer agents can be considered. A patient with purely cutaneous DD should be given regular stool guaiac tests to test for internal bleeding. Tissue specimens can help strengthen the diagnosis of DD, but many clinical and histologic features of DD can rarely be found in patients with lupus; therefore a patient's clinical, histologic, and laboratory data must be integrated to definitively support the diagnosis of DD.

Older treatments for MAP and cutaneous DD include anticoagulation with either *coumarins* or *heparin*, platelet inhibitors such as *aspirin* and *dipyridamole*, and agents with fibrinolytic activity, including *phenformin*, and immunosuppression with either *ciclosporin* or *azathioprine*. *Intravenous immunoglobulin* has been used but with limited success. Topical *nicotine patches* have been used with success.

MAP is no longer an incurable disease. Reports have noted that initiation and continuing treatment with *eculizumab*, a monoclonal antibody directed against the complement protein C5, can put patients with systemic MAP into remission. Although the sample size of the use of eculizumab is small and most of the cases are unpublished, it seems that eculizumab is the treatment of choice for systemic MAP. The dosing for this treatment is still not clear, but is likely at the high end of published doses (900 mg intravenously or perhaps higher given continuously for treatment of MAP). The success of eculizumab suggests that MAP is a vascular rather than an immune disease. As eculizumab is a very expensive complex treatment, its use is not recommended for purely cutaneous DD. *Treprostinil*, a synthetic analog of prostacyclin (PGI₂), has shown some promise when combined with eculizumab.

Specific Investigations

- Physical examination
- Tissue biopsy (skin primarily, but also tissue from the intestines and other internal organs)
- Complete blood count
- Stool guaiac
- Antinuclear antibody titer
- Protein C, protein S, and factor V Leiden; antithrombin III; and

homocysteine levels

- Anticardiolipin antibody titer
- Antiphospholipid antibody titer
- Endoscopy of the GI tract (i.e., stomach, esophagus, duodenum, colon, rectum)
- Laparoscopy of the intestine
- Clinical integration of the aforementioned data

First-Line Therapies

• Eculizumab	D
• Treprostinil	D

A 32-year-old man with a rash, myalgia, and weakness

Burgin S, Stone JH, Shenoy-Bhangle AS, McGuone D. N Engl J Med 2014; 370: 2327–37.

A man with a rash, myalgia, and weakness

Shapiro L, Whelan P, Magro C. N Engl J Med 2014; 371: 1361.

The effects of eculizumab on the pathology of malignant atrophic papulosis

Magro CM, Wang X, Garrett-Bakelman F, Laurence J, Shapiro LS, DeSancho MT. Orphanet J Rare Dis 2013; 8: 185.

Effective treatment of malignant atrophic papulosis (Köhlmeier-Degos disease) with treprostinil — early experience

Shapiro LS, Toledo-Garcia AE, Farrell JF. Orphanet J Rare Dis 2013. 8: 52.

Degos disease: a C5b-9/interferon- α -mediated endotheliopathy

syndrome

Magro CM, Poe JC, Kim C, Shapiro L, Nuovo G, Crow MK, et al. *Am J Clin Pathol* 2011; 135: 599–610.

Commentary on Degos disease: a C5b-9/interferon- α -mediated endotheliopathy syndrome by Magro et al: a reconsideration of Degos disease as hematologic or endothelial genetic disease

Scheinfeld N. *Dermatol Online J* 2011; 17: 6.

The initial enthusiasm for eculizumab as monotherapy may have faded. Burgin et al note that eculizumab (900 mg/d) failed as treatment for advanced systemic atrophic papulosis with GI involvement, with death as the outcome. Shapiro et al. note that only two patients initially given eculizumab as monotherapy are still alive; they instead use a combination of subcutaneous treprostinil and eculizumab. Eculizumab, if given early enough, may help abate malignant atrophic papulosis, but as monotherapy it is not instrumental in controlling it. With four patients treated, there have been no deaths. The first two are now 6-year survivors. Each of them had been critically ill in ICU settings before therapy. This information is important because malignant atrophic papulosis without treatment or hope of treatment is lethal, and patients should be directed toward those experienced with treatment, as eculizumab alone may not work.

Other reports have supported the use of eculizumab for systemic Degos disease, but informal communication to the author noted that despite treatment with eculizumab, some patients with systemic Degos disease have died. One report noted two patients with Degos disease in whom eculizumab failed. One had overlapping lupus, and the other had pulmonary hypertension. The pulmonary hypertension patient was treated with treprostinil, and cutaneous MAP lesions resolved but disabling digital pain remained. In the patient with Degos disease and lupus, treprostinil temporarily resulted in clearing of hematuria and central nervous system (CNS) symptoms, and magnetic resonance imaging (MRI) finding improvements.

Second-Line Therapies

• Coumadin (warfarin)	E
• Heparin	E
• Aspirin	E
• Dipyridamole	E
• Phenformin	E
• Ethylestrenol	E
• Nicotine patches	E
• Lansoprazole (for GI ulceration)	E
• Ciclosporin	E

Malignant atrophic papulosis

Degos R. Br J Dermatol 1979; 100: 21–35.

Numerous clinical manifestations have been reported and can affect the skin, mucosa, GI tract, viscera, and CNS and may require surgical intervention or fibrinolytic therapy. Anticoagulants have shown the most favorable responses.

Malignant atrophic papulosis: treatment with aspirin and dipyridamole

Stahl D, Thomsen K, Hou-Jensen K. Arch Dermatol 1978; 114: 1687–9.

A case report of a patient treated with aspirin 0.5 g twice daily and dipyridamole 50 mg three times daily arrested the development of both cutaneous lesions and systemic symptoms. Discontinuation of therapy resulted in no relapses 4 months posttherapy.

Malignant atrophic papulosis in an infant

Torrelo A, Sevilla J, Mediero I, Candelas D, Zambrano A. Br J

Dermatol 2002; 146: 916–8.

A 7-month-old female with cutaneous lesions, vomiting, and poor weight gain was treated successfully with aspirin 12 mg/kg daily and dipyridamole 4 mg/kg daily in three divided doses.

Effect of fibrinolytic treatment in malignant atrophic papulosis

Delaney TJ, Black MM. Br Med J 1975; 3: 415.

The further development of cutaneous disease was halted in a 42-year-old female patient placed on phenformin 50 mg twice daily and ethylestrenol 2 mg four times daily. Withdrawal of therapy resulted in relapse that responded to reinstitution of therapy.

Penile ulceration in fatal malignant atrophic papulosis (Degos disease)

Thompson KF, Highet AS. Br J Dermatol 2000; 143: 1320–2.

A fatal outcome in a patient who initially presented with penile ulceration and was treated with aspirin and dipyridamole but could not tolerate the therapy. Ciclosporin resulted in clinical improvement. Neurologic and GI symptoms developed, and lansoprazole resulted in healing of gastric ulceration. Atrial fibrillation and pleuritic pain were treated with heparin with clinical improvement. Continued symptoms prompted trials of tacrolimus, prednisolone, azathioprine, and cyclophosphamide, without success.

A case of malignant atrophic papulosis successfully treated with nicotine patches

Kanekura T, Uchino Y, Kanzaki T. Br J Dermatol 2003; 149: 660–2.

Nicotine patches that released 5 mg every 24 hours were applied daily and resulted in clearing of skin lesions. Three weeks after withdrawal of the patches, lesions recurred and again responded to therapy. The patient had no systemic involvement.

Third-Line Therapies

• Azathioprine	E
• Cyclophosphamide	E
• Tacrolimus	E
• Intravenous immunoglobulin	E
• Ultraviolet B therapy	E

Inefficacy of intravenous immunoglobulins and infliximab in Degos' disease

De Breucker S, Vandergheynst F, Decaux G. Acta Clin Belg 2008; 63: 99–102.

A 60-year-old man who presented with systemic Degos disease died despite anticoagulants, prednisone, intravenous immunoglobulins, and infliximab (Remicade).

The use of intravenous immunoglobulin in cutaneous and recurrent perforating intestinal Degos disease (malignant atrophic papulosis)

Zhu KJ, Zhou Q, Lin AH, Lu ZM, Cheng H. Br J Dermatol 2007; 157: 206–7.

A 38-year-old Chinese woman with Degos disease unresponsive to a variety of therapies was treated with one course of high-dose IVIG therapy (0.4 g/kg) daily for 5 days. A week later a dramatic improvement of the lesions and general condition was noticed. During the next 11 months of follow-up, the patient had no new skin lesions or GI complaints.

A fatal case of malignant atrophic papulosis (Degos' disease) in a man with factor V Leiden mutation and lupus anticoagulant

Hohwy T, Jensen MG, Tøttrup A, Steiniche T, Fogh K. Acta Derm Venereol 2006; 86: 245–7.

A 33-year-old man presented with a widespread skin eruption

consistent with malignant atrophic papulosis and died 2.5 years after onset of the disease. The patient was treated with narrowband ultraviolet (UV) B, prednisolone, and, later, aspirin, pentoxifylline, and warfarin without effect.

A case of systemic malignant atrophic papulosis (Köhlmeier-Degos' disease)

Fernández-Pérez ER, Grabscheid E, Scheinfeld NS. J Natl Med Assoc 2005; 97: 421–5.

Despite use of ciclosporin, prednisone, cidofovir, IVIG, and anticoagulant therapy a young male patient died. The therapy had no effect on the course of the patient's disease.

Malignant atrophic papulosis of Degos. Report of a patient who failed to respond to fibrinolytic therapy

Howsden SM, Hodge SJ, Herndon JH, Freeman RJ. Arch Dermatol 1976; 112: 1582–8.

A 21-year-old female died of complications from MAP after therapy with phenformin, ethylestrenol, aspirin, niacin, and low-molecular-weight dextran.

Benign familial Degos disease worsening during immunosuppression

Powell J, Bordea C, Wojnarowska J, Farrell AM, Morris PJ. Br J Dermatol 1999; 141: 524–7.

A 61-year-old woman with Degos disease underwent a cadaveric kidney transplant. Her condition worsened with the use of prednisolone, azathioprine, and ciclosporin.

[An autopsy case of Degos disease with ascending thoracic myelopathy]

Sugai F, Sumi H, Hara Y, Kajiyama K, Morino H, Fujimura H. Rinsho Shinkeigaku 1998; 38: 1049–53. [In Japanese].

Aggressive therapies, including pulsed-dose methylprednisolone and cyclophosphamide, were not successful in this 44-year-old man with Degos disease complicated by thoracic transverse myelopathy, with the patient ultimately succumbing to respiratory failure.

Malignant melanoma

Sarah Utz, Philip Friedlander, and Orit Markowitz

Melanoma is the leading cause of death among all cutaneous diseases in the United States. In 2015 it was estimated that 73,870 new cases of melanoma were diagnosed in the United States, and nearly 9940 patients died from this cancer.

Management Strategy

Early detection of melanoma is paramount in its management. Physicians and patients must become familiar with the *ABCDE signs of melanoma*: Asymmetry, Border, Color, Diameter, and Evolution. A specificity of 88% and sensitivity of 73% have been reported if two out of three of the following characteristics are noted on physical examination: irregular outline, diameter >6 mm, and color variegation. Even expert clinicians misdiagnose melanoma in up to one third of cases, and only *biopsy and histologic examination* can provide a definitive diagnosis.

Important in the management of melanoma is *primary prevention* (risk reduction) and *secondary prevention* (early detection). The National Institutes of Health (NIH) stresses the importance of screening programs and regular skin examinations by health professionals. The American Academy of Dermatology Task Force recommends follow-up one to four times a year for 2 years after a diagnosis of melanoma, depending on the thickness of the lesion and other risk factors, such as a family history of melanoma, and then once or twice a year thereafter. Other modalities such as *dermoscopy* and the recently Food and Drug Administration (FDA)-approved *MelaFind* are noninvasive tools aiding in identification of high-risk pigmented lesions.

The first step in the diagnosis of suspected melanoma is to obtain a biopsy. If total excision is not practical, a full-thickness incisional biopsy is acceptable.

The goal of surgical management of primary cutaneous melanoma is to achieve negative histologic margins with wide local excision to prevent recurrence and metastases. The current surgical margin guidelines from the National Comprehensive Cancer Network (NCCN) are based on Breslow depth ([Table 149.1](#)).

The standard treatment for stage IA melanoma is *wide local excision*. Total excision of primary melanoma with wide margins offers the best chance for cure. However, melanoma cells may extend noncontiguously for several millimeters beyond the visible lesion. The current recommendation for melanoma in situ may need to be extended to 9-mm margins.

Table 149.1

Current melanoma excisional margin guidelines

Tumor thickness	Recommended clinical margins
-----------------	------------------------------

In situ	0.5 cm
≤1.0 mm	1.0 cm
1.01–2 mm	1–2 cm
2.01–4 mm	2.0 cm
>4 mm	2.0 cm

The NCCN suggests that *sentinel lymph node (SLN) biopsy* be discussed and offered to patients in those with melanomas greater than 1 mm thick or 0.76 to 1 mm with ulceration or additional adverse features such as increased mitotic rate or lymphovascular invasion. The presence of melanoma in the SLN is the most significant factor in the prognosis of a patient with localized cutaneous melanoma. If the SLN is positive, a *completion lymphadenectomy* of all involved nodal basins is considered. The overall effect of completion lymphadenectomy after a positive SLN has yet to show survival benefit. An *elective lymphadenectomy* may also be performed, but it can result in significant morbidity and remains controversial.

For patients with clinically positive lymph nodes, a diagnostic nodal biopsy (e.g., fine-needle biopsy) is recommended, and, if positive, a *therapeutic lymphadenectomy* is performed. Adjuvant therapy approved by the FDA for the management of stage III or deep stage II melanomas includes high-dose *interferon (IFN)- α_{2b}* , which most consistently confers a disease-free survival benefit. More recently, *ipilimumab*, an immune checkpoint modulator that blocks cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4), was approved for the adjuvant management of patients with melanoma involving regional lymph nodes >1 mm who have undergone complete lymph node dissection. The approval was based on recurrence-free survival benefit in patients treated with ipilimumab relative to placebo. Patients with satellitosis or in-transit metastases on an extremity are candidates for regional treatment with *isolated limb hyperthermic perfusion/infusion* with chemotherapeutic agents such as melphalan. *Talimogene laherparepvec*, an oncolytic herpesvirus engineered to secrete granulocyte-macrophage colony-stimulating factor (GM-CSF), was approved for intratumoral injection as treatment of unresectable subcutaneous, cutaneous, and nodal lesions.

Stage IV melanoma has a very poor prognosis, with patients demonstrating a 5-year survival below 5%. The presence of BRAF mutations has transformed the systemic management of stage IV melanoma. Until 2011, only two treatments, *dacarbazine* and *high-dose*

interleukin-2 (HD-IL-2), were FDA approved for the treatment of stage IV melanoma. HD-IL-2 requires administration as an inpatient and can carry significant toxicity risks, including capillary leak syndrome, renal failure, and neurologic toxicity. Given its toxicity profile, only a very limited number of patients are appropriate candidates for this treatment.

It has become increasingly evident that melanoma is a molecularly heterogeneous disease. Recently sequencing of components of the MAPK pathway in a panel of cancer cell lines identified activating mutations in the downstream BRAF protein in 50% to 60% of melanomas. Over 90% of the mutations in BRAF occur at position 600, with the most common being a V600E mutation.

Vemurafenib and *dabrafenib* are potent inhibitors of V600E-mutated BRAF. Randomized phase III studies using V600E inhibitors as first-line systemic therapy in patients with stage IV melanoma demonstrated statistically significant survival benefit after treatment with a BRAF inhibitor compared with dacarbazine treatment. However, median progression-free survival is limited to approximately 6 months. As such, elucidating resistance mechanisms is extremely important. Inhibition of the MAPK pathway downstream of BRAF by using the MEK inhibitor *trametinib* also confers a significant overall survival benefit relative to treatment with chemotherapy in patients with V600-mutated melanoma. Concurrent inhibition of BRAF and MEK confers higher response rates and improved progression-free duration than single-agent treatment. Two combination regimens, vemurafenib plus cobimetinib and dabrafenib plus trametinib, are FDA approved as treatment in V600 BRAF-mutated melanoma. Treatment with the combination of dabrafenib plus trametinib has demonstrated overall survival benefit relative to single-agent vemurafenib treatment.

A subset of melanomas contains a mutation in the KIT gene as opposed to BRAF; these tumors have shown response to oral inhibitors of KIT but also with limited durability.

Immunotherapies offer the potential for longer lasting benefit than BRAF inhibition as demonstrated by the small subset of patients who develop durable responses to HD-IL-2. CTLA-4 is an immunomodulatory protein that downregulates T-cell activity. Inhibition of CTLA-4 using the monoclonal antibody ipilimumab has shown significant antitumor activity in melanoma. Treatment of stage IV melanoma patients with ipilimumab has an overall survival benefit

compared with treatment with a peptide vaccine. An overall survival benefit is also seen after treatment with the combination of ipilimumab and dacarbazine compared with treatment with single-agent dacarbazine.

Over the past few years, it has become increasingly clear that antibody-mediated inhibition of immunomodulatory proteins other than CTLA-4 are also efficacious. Targeting either the programmed death 1 protein (PD-1) or its ligand PD-L1 produced durable responses in a subset of patients with melanoma. PD-1 is an inhibitory receptor on T cells whose immunosuppressive ligand, PD-L1, is expressed on many melanomas. Two PD-1 inhibitors, *pembrolizumab* and *nivolumab*, are FDA approved as single agents for systemic treatment of stage IV melanoma. A randomized phase III trial demonstrated an overall survival benefit after treatment with nivolumab relative to dacarbazine. The rate of high-grade autoimmune toxicity also was lower in patients who received treatment with the PD-1 inhibitor. The Checkmate 067 phase III study compared treatment with ipilimumab alone, nivolumab alone, or combined ipilimumab plus nivolumab treatment in 945 patients with stage IV melanoma who have not received prior systemic therapy for advanced disease. Although median progression-free survival was 2.9 months, 6.9 months, and 11.5 months, respectively, the combination therapy led to higher rates of high-grade toxicity, with 55% of patients developing a grade 3 or higher adverse event. Overall survival data are not yet presented. At present, the optimal sequencing of targeted and immune therapies is still unclear.

Specific Investigations

- Dermoscopy
- Biopsy of primary site
- Sentinel lymph node biopsy
- Laboratory and imaging studies: chest radiograph, computed tomography (CT), magnetic resonance imaging (MRI), positron emission tomography (PET) scans
- MelaFind

Final version of 2009 American Joint Committee on Cancer (AJCC) melanoma staging and classification

Balch CM, Gershenwald JE, Soong SJ, Thompson JF, Atkins MB, Byrd DR, et al. J Clin Oncol 2009; 27: 6199–206.

This paper describes the updated staging system for cutaneous melanoma based on a multivariate analysis of 30,946 patients with stages I, II, and III and 7972 patients with stage IV. Specifically, in patients with localized melanoma, tumor thickness, mitotic rate, and ulceration were the most important prognostic factors. Mitotic rate replaced tumor invasion when defining T1b melanomas. In patients with regional metastases, the N category was determined by number of metastatic nodes, tumor burden, and ulceration of the primary lesion. All patients with microscopic nodal metastases are classified as stage III regardless of tumor burden. Elevated lactose dehydrogenase (LDH) was also included as an independent predictor of poor outcomes in patients with stage IV melanoma.

National Comprehensive Cancer Network. Clinical practice guidelines in oncology. V 1.2013

Coit DG, Andtbacka R, Anker CJ, Bichakjian CK, Carson WE 3rd, Daud A, et al. Available online:

http://www.nccn.org/professionals/physician_gls/pdf/melanoma.pdf.

Mitotic rate was added to the initial stratification of stage I and II melanoma. The extent of initial workup is controversial. Most agree that chest radiography and blood work are not necessary for stage IA melanoma. For stage IB and stage IIA melanomas, a baseline chest radiograph is optional because it is not sensitive or specific. Other imaging studies, such as CT, MRI, and/or PET scans, should be performed only to evaluate specific signs or symptoms or for stages III and IV. Fine-needle aspiration is indicated for stage III with macrometastases or in-transit metastases and stage IV. LDH is only indicated for stage IV. These guidelines also discuss frequency of follow-up visits and appropriate follow-up tests, both of which depend on the stage of the melanoma as well as other risk factors.

Incisional biopsy and melanoma prognosis

Bong JL, Herd RM, Hunter JA. J Am Acad Dermatol 2002; 46: 690–4.

A large retrospective case analysis using matched controls to investigate the influence of incisional biopsy on melanoma prognosis. A total of 5727 biopsied melanoma patients were examined, with 5.6% having undergone incisional biopsies. The authors conclude that melanoma prognosis is not influenced by an incisional procedure

before definitive excision of the tumor. Because of the histologic limitations of this procedure, however, the authors recommend that incisional biopsies be reserved for lesions that cannot be excised primarily or when clinical suspicion for melanoma is low.

The role of sentinel lymph node biopsy for melanoma: evidence assessment

Johnson TM, Sondak VK, Bichakjian CK, Sabel MS. *J Am Acad Dermatol* 2006; 54: 19–27.

In reviewing 1198 articles regarding melanoma sentinel node biopsy this paper discusses the evidence base behind the sentinel node hypothesis. The authors state that the available evidence overwhelmingly supports SLN status as the most powerful independent factor predicting survival, with highest sensitivity and specificity of any nodal staging test. They also discuss that SLN biopsy results in improved regional disease control. The article claims that, based on available evidence, there is a potential subset survival benefit for subclinical detection of nodal disease followed by immediate complete lymph node dissection (CLND). The article reviews the Multicenter Selective Lymphadenectomy Trial I (MSLT-1) interim results and discusses the morbidities of SLN biopsy. The authors conclude that current evidence supports the use of SLN biopsy in the management of melanoma.

Atlas of Dermoscopy

Marghoob AA, Braun R, Kopf AW, eds. London: Parthenon Publishing, 2005.

Dermoscopy increases the diagnostic sensitivity of melanoma in appropriately trained clinicians. In high-risk patients, the availability of baseline images for comparison permits the detection of melanomas that are growing or changing. Three-month-interval digital dermoscopy mole monitoring has demonstrated 93% sensitivity for lentigo maligna and in situ melanoma, and 96% sensitivity for invasive melanoma diagnosis. This clinician-oriented atlas is an up-to-date multiauthored text reviewing virtually every aspect of dermoscopy.

The performance of MelaFind: a prospective multicenter study

Monheit G1, Cognetta AB, Ferris L, Rabinovitz H, Gross K, Martini M, et al. *Arch Dermatol* 2011; 147: 188–94.

MelaFind is a fully automatic, noninvasive, computerized diagnostic system approved by the FDA in 2011. MelaFind identifies high-risk pigmented lesions that should be considered for biopsy to rule out melanoma, with a high sensitivity of 98.4% for thin pigmented melanomas over 2 mm in diameter.

First-Line Therapies

• Surgical excision	B
• Selective lymphadenectomy	C
• Elective lymphadenectomy	C

Surgical margins for melanoma in situ

Kunishige JH, Brodland DG, Zitelli JA. J Am Acad Dermatol 2012; 66: 438–44.

The previously accepted 5-mm margin to surgically excise melanoma in situ was shown to be inadequate in several studies. This prospective series of 1072 patients with 1120 melanomas in situ investigated the minimal surgical margins required to remove 97% of all tumors. This group determined that 86% of all melanomas in situ were completely excised with 6-mm margins, and the minimum surgical margin required to successfully remove 98.9% of all melanomas in situ was 9 mm. The 9-mm margin was found to be statistically superior to the 6-mm margin.

Excision margins in high-risk malignant melanoma

Thomas JM, Newton-Bishop J, A'Hern R, Coombes G, Timmons M, Evans J, et al. N Engl J Med 2004; 350: 757–66.

This is a randomized clinical trial with 900 subjects comparing 1-cm and 3-cm margins in high-risk tumors. The median follow-up was 60 months. A 1-cm margin was associated with a significantly increased risk of locoregional recurrence. There were 128 deaths attributable to melanoma in the group with 1-cm margins, compared with 105 in the

group with 3-cm margins, but overall survival was similar in the two groups.

Overview and update of the phase III Multicenter Selective Lymphadenectomy Trials (MSLT-I and MSLT-II) in melanoma

Morton DL. Clin Exp Metastasis 2012; 29: 699–706.

The Multicenter Selective Lymphadenectomy Trial II (MSLT-II) was designed to investigate if SLN biopsy may be therapeutic as well as diagnostic and if complete lymph node dissection could therefore be avoided in most patients with SLN metastases. Its primary outcome is melanoma-specific survival. MSLT-II is a randomized phase III trial of SLN biopsy plus complete lymph node dissection versus SLN biopsy plus high-definition ultrasound observation of lymph nodes in patients with SLN metastases confirmed by histopathology or reverse transcription polymerase chain reaction (RT-PCR). High-definition ultrasound can detect metastases as small as 4 mm.

Sentinel lymph node biopsy for melanoma: American Society of Clinical Oncology and Society of Surgical Oncology joint clinical practice guideline

Wong SL, Balch CM, Hurley P, Agarwala SS, Akhurst TJ, Cochran A, et al. Ann Surg Oncol 2012; 19: 3313–24.

This practice guideline was developed by the American Society of Clinical Oncology and Society of Surgical Oncology in an effort to provide an evidence-based guideline for the use of SLN biopsy in staging patients with newly diagnosed melanoma. A systematic review of 73 studies concluded that SLN biopsy is recommended for patients with intermediate-thickness melanomas of any anatomic site. Additionally, SLN biopsy may be recommended for staging purposes and to facilitate regional disease control. Complete lymph node dissection is recommended for all patients with a positive SLN biopsy and achieves good regional disease control.

Elective lymph node dissection in patients with melanoma: systematic review and meta-analysis of randomized controlled trials

Lens MB, Dawes M, Goodacre T, Newton-Bishop JA. Arch Surg 2002; 137: 458–61.

This is a large systematic review and meta-analysis of randomized controlled trials comparing elective lymph node dissection with

surgery delayed until the time of clinical recurrence. Elective lymphadenectomy shows no significant overall survival benefit for patients undergoing elective lymph node dissection.

Second-Line Therapies

• Pegylated IFN- α_{2b}	A
• Paclitaxel and carboplatin	D
• Imiquimod	E
• Interleukin-2	B
• Isolated limb perfusion	E
• Bcl-2 antisense and dacarbazine	A
• Dacarbazine	A
• Vemurafenib	A
• Trametinib	B
• Imatinib	B
• Ipilimumab	A
• Pembrolizumab	A
• Vemurafenib and cobimetinib	A
• Nivolumab and ipilimumab	A
• Ipilimumab plus dacarbazine	A

The Society for Immunotherapy of Cancer consensus statement on tumor immunotherapy for the treatment of cutaneous melanoma

Kaufman HL, Kirkwood JM, Hodi FS, Agarwala S, Amatruda T, Bines

SD, et al. Nat Rev Clin Oncol 2013;10: 588-98.

This comprehensive review provides recommendations for the immunotherapy use in patients with high-risk and advanced-stage melanoma in the United States. The recommendations were made by a panel of clinicians, nurses, and patient advocates that used a literature review of high-quality, peer-reviewed studies from 1992–2012. The panel identified roles for IFN- α_{2b} , pegylated-IFN- α_{2b} , interleukin-2 (IL-2), and ipilimumab.

Adjuvant therapy with pegylated interferon alfa-2b versus observation alone in resected stage III melanoma: final results of EORTC 18991, a randomised phase III trial

Eggermont AM, Suci S, Santinami M, Testori A, Kruit WH, Marsden J, et al. Lancet 2008; 372: 117–26.

This study assessed whether long-term (5 years) adjuvant pegylated IFN- α_{2b} therapy could be well tolerated while maintaining recurrence-free survival. A total of 1256 patients with resected stage III melanoma were randomly assigned to an observation group ($n = 629$) or pegylated IFN- α_{2b} group ($n = 627$) for 5 years. Relapse-free survival was significantly better in the IFN treatment group compared with the observation group (45.6% vs. 38.9%), but there was no significant benefit to overall survival. Subsequently, pegylated IFN- α_{2b} was approved by the FDA in 2011 as adjuvant therapy for patients with stage III melanoma.

Adjuvant ipilimumab versus placebo after complete resection of high-risk stage III melanoma (EORTC 18071): a randomised, double-blind, phase 3 trial

Eggermont AM, Chiarion-Sileni V, Grob JJ, Dummer R, Wolchok JD, Schmidt H, et al. Lancet Oncol 2015; 16: 522.

This study aimed to address whether ipilimumab could have a role as adjuvant therapy for patients with completely resected stage III melanoma at high risk of recurrence. In a double-blind phase III trial looking at 951 patients, ipilimumab was found to significantly improve recurrence-free survival for patients with completely resected, high-risk, stage III melanoma.

Improved survival with ipilimumab in patients with metastatic melanoma

Hodi FS, O'Day SJ, McDermott DF, Weber RW, Sosman JA, Haanen JB, et al. *N Engl J Med* 2010; 363: 711–23.

The FDA approved ipilimumab, a monoclonal antibody against the immune checkpoint receptor CTLA-4, based on this randomized phase III trial. A total of 676 patients with unresectable stage III or IV melanoma were assigned to three groups: ipilimumab plus glycoprotein 100 peptide vaccine (gp100) ($n = 403$), ipilimumab alone ($n = 137$), or gp100 alone ($n = 136$). Ipilimumab, with or without gp100 vaccine, compared with gp100 alone, significantly improved overall survival in patients with previously treated metastatic melanoma (10.1 months for ipilimumab alone, 10.0 months for combination therapy, vs. 6.4 months for gp100 alone).

Pembrolizumab versus ipilimumab in advanced melanoma

Robert C, Schachter J, Long GV, Arance A, Grob JJ, Mortier L, et al. *N Engl J Med* 2015; 372: 2521–32.

This study was a phase III randomization of 834 patients with stage IV melanoma, who were not previously treated with an inhibitor of CTLA-4 or PD-1, to treatment with ipilimumab or pembrolizumab. A statistically significant improvement in response rate, 6-month progression-free survival, and 12-month overall survival favoring PD-1 inhibitor treatment was observed. The rate of high-grade autoimmune toxicity was also lower in patients who received treatment with the PD-1 inhibitor.

Combined vemurafenib and cobimetinib in BRAF-mutated melanoma

Larkin al J, Ascierto PA, Dréno B, Atkinson V, Liskay G, Maio M, et al. *N Engl J Med* 2014; 371: 1867–74.

This study randomly assigned 495 patients with previously untreated, unresectable, locally advanced or metastatic BRAF V600 mutation–positive melanoma to either vemurafenib and cobimetinib combination or vemurafenib and placebo. Median progression-free survival showed a statistically significant difference of 9.9 months in the combination group and 6.2 months in the control.

Nivolumab in previously untreated melanoma without BRAF mutation

Robert C, Long GV, Brady B, Dutriaux C, Maio M, Mortier L, et al. *N Engl J Med* 2015; 372: 320–30.

This study randomly assigned 418 previously untreated patients with metastatic melanoma without a BRAF mutation to either nivolumab or dacarbazine. At 1 year, there was statistically significant increase in overall survival, with 72.9% in the nivolumab group compared with 42.1% in the dacarbazine group. Median progression-free survival was 5.1 months in the nivolumab group versus 2.2 months in the dacarbazine group.

Combined nivolumab and ipilimumab or monotherapy in untreated melanoma

Larkin J, Hodi FS, Wolchok JD. N Engl J Med 2015; 373: 23–34.

The Checkmate 067 phase III study compared treatment with ipilimumab alone, nivolumab alone, or combined ipilimumab plus nivolumab treatment in 945 patients with stage IV melanoma who have not received prior systemic therapy for advanced disease. Although median progression-free survival was 2.9 months, 6.9 months, and 11.5 months, respectively, the combination therapy led to higher rates of high-grade toxicity, with 55% of patients developing a grade 3 or higher adverse event. Overall survival data are not yet presented.

Combination of paclitaxel and carboplatin as second-line therapy for patients with metastatic melanoma

Rao RD, Holtan SG, Ingle JN, Croghan GA, Kottschade LA, Creagan ET, et al. Cancer 2006; 106: 375–82.

This was a retrospective review article including 31 patients who received combination treatment after other treatment failures, most of which were post-temozolomide (post-TMZ) or post-dacarbazine (post-DTIC). The authors concluded that the clinical benefit rates appear to be at least as good as for most other therapies considered standard for metastatic melanoma (albeit in the prebiologic era), and the data provide justification for further testing of this drug combination in the first-line setting.

Locoregional cutaneous metastases of malignant melanoma and their management

Wolf IH, Richtig E, Kopera D, Kerl H. Dermatol Surg 2004; 30: 244–7.

This article discussed the palliative benefits seen with application of topical imiquimod 5% cream three times weekly to cutaneous metastases with a 1-cm margin. In a five-patient sample, complete

clinical and histopathologic remission of locoregional cutaneous metastases of malignant melanoma occurred in two and partial remission occurred in one, with no regression in the remaining two patients.

High-dose recombinant interleukin 2 therapy for patients with metastatic melanoma: analysis of 270 patients treated between 1985 and 1993

Atkins MB, Lotze MT, Dutcher JP, Fisher RI, Weiss G, Margolin K, et al. J Clin Oncol 1999; 17: 2105–16.

In this intention-to-treat analysis, 270 patients with metastatic melanoma were entered into eight clinical trials conducted between 1985 and 1993. These patients received at least one dose of high-dose recombinant IL-2 by IV infusion every 8 hours for up to 14 consecutive doses over 5 days as clinically tolerated, with a second cycle performed after 6 to 9 days of rest. Additional courses were repeated every 6 to 12 weeks as tolerated in stable or responding patients. The overall response rate was 16%, with 6% of patients achieving complete responses. The median response duration in partial responders was 5.9 months. Severe toxicities reversed rapidly after therapy was completed.

Durable complete responses with high-dose bolus interleukin-2 in patients with metastatic melanoma who have experienced progression after biochemotherapy

Tarhini AA, Kirkwood JM, Gooding WE, Cai C, Agarwala SS. J Clin Oncol 2007; 25: 3802–7.

In this intention-to-treat clinical trial, 26 patients with metastatic melanoma with disease progression on or after biochemotherapy (BCT) (cisplatin, vinblastine, dacarbazine, IL-2, and IFN- α_{2b}) received high-dose bolus IL-2. All patients except three received at least two cycles. Four patients (all with stage M1a disease) experienced complete responses.

Management of in-transit melanoma of the extremity with isolated limb perfusion

Fraker DL. Curr Treat Options Oncol 2004; 5: 173–84.

The primary use of ILP (isolated limb perfusion) is in the treatment of satellitosis and in-transit metastasis. ILP involves very high doses of chemotherapeutic agents, usually melphalan, administered

through femoral, iliac, or axillary vessels to isolated anatomic regions. Reports have shown that the addition of tumor necrosis factor to melphalan may improve response rates, but no clear benefit has been demonstrated.

Bcl-2 antisense (oblimersen sodium) plus dacarbazine in patients with advanced melanoma: the Oblimersen Melanoma Study Group

Bedikian AY, Millward M, Pehamberger H, Conry R, Gore M, Trefzer U, et al. *J Clin Oncol* 2006; 24: 4738–45.

In one of the largest randomized controlled studies in advanced melanoma, 771 patients were randomly assigned to treatment with oblimersen–dacarbazine (386 patients) or dacarbazine (385 patients). The use of oblimersen with dacarbazine safely improves outcomes in patients with advanced melanoma, particularly those with normal baseline LDH. Because the patients in this study had advanced stage III and IV melanoma, the authors suggest examination of patients with less advanced disease in whom Bcl-2 expression has been confirmed.

Inhibition of mutated, activated BRAF in metastatic melanoma

Flaherty KT, Puzanov I, Kim KB, Ribas A, McArthur GA, Sosman JA, et al. *N Engl J Med* 2010; 363: 809–19.

This landmark multicenter, phase I, dose-escalation trial of PLX4032, an oral inhibitor of V600E-mutated BRAF, demonstrated complete or partial tumor regression in the majority of patients with metastatic melanoma. Fifty-five patients (49 had melanoma) were enrolled in the dose-escalation phase, with an additional 32 patients with V600E-mutated BRAF melanomas enrolled in the extension phase, allowing the maximum dose that could be administered without adverse effects. In the dose-escalation cohort, among 16 patients with V600E-mutated BRAF melanoma, 10 patients demonstrated partial response and 1 had a complete response. In the extension cohort, 24 patients had a partial response and 2 had a complete response. Median progression-free survival for all patients was over 7 months. Interestingly, responses to PLX4032 were seen as early as 14 days after initiating treatment, as seen on fludeoxyglucose (FDG)-labeled PET imaging.

Improved survival with vemurafenib in melanoma with BRAF

V600E mutation

Chapman PB, Hauschild A, Robert C, Haanen JB, Ascierto P, Larkin J, et al. *N Engl J Med* 2011; 364: 2507–16.

Vemurafenib, a specific inhibitor of the V600E mutation, was FDA approved in 2011 based on this phase III randomized controlled trial comparing vemurafenib with dacarbazine in 675 patients with previously untreated melanoma with the V600E BRAF mutation. At 6 months, the overall survival in the vemurafenib group was 84% compared with 64% in the dacarbazine group. At interim analysis of this trial, crossover from dacarbazine to vemurafenib was recommended due to the significantly improved rates of overall and progression-free survival in the vemurafenib group.

Improved survival with MEK inhibition in BRAF-mutated melanoma

Flaherty KT, Robert C, Hersey P, Nathan P, Garbe C, Milhem, et al. *N Engl J Med* 2012; 367: 107–14.

In previous trials, MEK inhibition by trametinib showed promise. In this phase III open-label trial, trametinib, compared with chemotherapy, significantly improved rates of progression-free and overall survival among patients with metastatic melanoma containing the V600E or V600K BRAF mutation. A total of 322 patients were randomly assigned to receive either oral trametinib daily or chemotherapy in a 2:1 ratio (intravenous dacarbazine or paclitaxel) every 3 weeks. Patients in the chemotherapy cohort who demonstrated disease progression were permitted to cross over to receive trametinib. Median progression-free survival was 4.8 months in the trametinib group and 1.5 months in the chemotherapy group. At 6 months, the overall rate of survival was 81% in the trametinib group and 67% in the chemotherapy group despite crossover.

KIT as a therapeutic target in metastatic melanoma

Carvajal RD, Antonescu CR, Wolchok JD, Chapman PB, Roman RA, Teitcher J, et al. *J Am Med Assoc* 2011; 305: 2327–34.

In this single-group, open-label, phase II trial, treatment with the KIT inhibitor imatinib showed significant clinical responses in patients with advanced melanoma harboring KIT mutations. Patients ($n = 205$) with metastatic melanoma were screened for the presence of KIT mutations. Fifty-one patients were identified with this mutation, and 28 patients from this group were treated. These 28 patients had

advanced unresectable melanoma arising from acral, mucosal, and chronically sun-damaged areas. Imatinib was administered orally twice daily. The overall durable response rate was 16% with a median time to progression of 12 weeks and median overall survival of 46.3 weeks.

Third-Line Therapies

• Radiation therapy	B
• Mohs micrographic surgery	B

The benefits of adjuvant radiation therapy after therapeutic lymphadenectomy for clinically advanced, high-risk, lymph node-metastatic melanoma

Agrawal S, Kane JM 3rd, Guadagnolo BA, Kraybill WG, Ballo MT. Cancer 2009; 115: 5836–44.

This large retrospective review evaluated the role of adjuvant radiation therapy on regional recurrence and survival after therapeutic lymphadenectomy for clinically advanced lymph node metastatic melanoma. A total of 615 patients were chosen based on criteria for high risk of regional nodal relapse. At a follow-up period of 5 years, regional recurrence was found in 10.2% of patients in the adjuvant radiation therapy group compared with 40.6% in the observation group.

Mohs micrographic surgery for the treatment of melanoma

Hui AM, Jacobson M, Markowitz O, Brooks NA, Siegel DM. Dermatol Clinics 2012; 30: 503–15.

The article discusses the current literature on the utility of Mohs micrographic surgery for the treatment of melanoma in situ, with an extensive review of Mohs technique, the latest advances in immunohistochemical staining, and outcomes.

Mastocytoses

Nicholas A. Soter

The mastocytoses are a group of disorders of mast cell proliferation that may exhibit both cutaneous and systemic features. Clinical manifestations result from mast cell activation and from infiltration of various organs. The World Health Organization has classified mastocytosis into disease categories: cutaneous mastocytosis, indolent systemic mastocytosis, systemic mastocytosis with a nonmast-cell clonal hematologic disorder, aggressive systemic mastocytosis, mast

cell leukemia, mast cell sarcoma, and extracutaneous mastocytoma. The most frequent site of organ involvement in individuals with mastocytosis is the skin. Cutaneous forms include urticaria pigmentosa (shown here), mastocytoma, diffuse and erythrodermic cutaneous mastocytosis, and telangiectasia macularis eruptiva perstans. An international task force has proposed a revised classification of cutaneous mastocytosis into maculopapular cutaneous mastocytosis with monomorphic and polymorphic variants, diffuse cutaneous mastocytosis, and cutaneous mastocytoma, with the elimination of telangiectasia macularis eruptiva perstans. The cutaneous forms of mastocytosis may be present with or without systemic manifestations. In pediatric patients, the cutaneous lesions usually are not associated with systemic involvement and often have spontaneous resolution around puberty. In adult patients, the cutaneous lesions usually are chronic and are associated with systemic mastocytosis. Adult patients should be classified because the type and stage of systemic mastocytosis has therapeutic and prognostic implications. Only the treatment of the cutaneous features will be discussed.

Management Strategy

An important aspect of therapy of the cutaneous lesions of mastocytosis is avoidance of triggering factors, which may include temperature changes, friction, physical exertion, ingestion of alcohol, the use of nonsteroidal antiinflammatory agents or opiate analgesics, and emotional stress. Of concern is the possibility of anaphylaxis after stings by *Hymenoptera* spp., which may occur even in patients receiving venom immunotherapy.

A history seeking systemic features should be undertaken, as well as a physical examination to determine the types of skin lesions and to assess for lymphadenopathy and hepatosplenomegaly. The presence of specific systemic manifestations will determine the type of specialty physician to whom a referral should be made for further evaluation.

Patients with systemic mastocytosis require long-term follow-up because associated nonmast-cell clonal hematologic disorders, such as myelodysplastic or myeloproliferative syndromes and lymphoproliferative disorders, may develop.

A skin biopsy should be obtained in all individuals with cutaneous

lesions. A complete blood count with differential analysis, a blood chemistry profile that includes liver function tests, and a blood tryptase level should be obtained in all patients with cutaneous lesions, except those with mastocytomas.

In many cases cutaneous mastocytomas may involute spontaneously; they rarely are described in adults. Childhood urticaria pigmentosa regresses spontaneously in approximately 50% of cases and urticaria pigmentosa in adults in 10%. Diffuse and erythrodermic cutaneous mastocytosis usually resolves spontaneously during childhood. Telangiectasia macularis eruptiva perstans tends to be a chronic condition.

Most of the therapeutic reports have been in patients with urticaria pigmentosa and, to a lesser extent, in diffuse and erythrodermic cutaneous mastocytosis. The major therapeutic measure is the administration of *oral H₁ antihistamines* to alleviate pruritus and whealing. *Oral disodium cromoglycate* has been efficacious in some individuals. The role and efficacy of topical high-potency glucocorticoid preparations with plastic-film occlusion, of narrowband ultraviolet B (NB-UVB) phototherapy, of psoralens and ultraviolet A (PUVA) photochemotherapy, and UVA1 phototherapy have not been subjected to controlled clinical trials or remain anecdotal. Cyto-reductive therapy to reduce mast cell proliferation is not recommended in patients with only cutaneous manifestations. There is no therapy that will eradicate the mast cells in the cutaneous lesions.

Specific Investigation

- Skin biopsy

Cutaneous manifestations in patients with mastocytosis: consensus report of the European Competence Network on Mastocytosis; the American Academy of Allergy, Asthma & Immunology; and the European Academy of Allergology and Clinical Immunology

Hartmann K, Escribano L, Grattan C, Brackow K, Carter MC, Alvarez-Twose I, et al. *J Allergy Clin Immunol* 2016; 37: 35–45.

The major criterion for cutaneous involvement in patients with mastocytosis is typical skin lesions that are associated with Darier

sign. Minor criteria include increased numbers of mast cells in biopsy specimens of lesional skin and an activating KIT mutation in lesional skin tissue. In lesional skin biopsy specimens, the number of mast cells is increased four to eightfold, which is about 40 mast cells/mm². The use of an antibody against tryptase should be the standard histochemical marker to detect and quantitate mast cells. No specific, aberrantly expressed marker of clonal cutaneous mast cells has been identified.

First-Line Therapies

• H ₁ antihistamines	A
• H ₂ antihistamines	D
• Disodium cromoglycate	A

Comparison of azelastine and chlorpheniramine in the treatment of mastocytosis

Friedman BS, Santiago ML, Berkebile C, Metcalfe DD. J Allergy Clin Immunol 1993; 92: 520–6.

In a double-blind, randomized, crossover trial in 13 subjects with urticaria pigmentosa and systemic mastocytosis, the administration of both azelastine and chlorpheniramine for 4 weeks was associated with a reduction in pruritus.

Rupatadine improves quality of life in mastocytosis: a randomized, double-blind, placebo-controlled trial

Siebenhaar F, Förtch A, Krause K, Weller K, Metz M, Magerl M, et al. Allergy 2013; 68: 949–52.

In a double-blind, randomized, placebo-controlled, crossover trial in 7 patients with cutaneous mastocytosis and in 23 with indolent systemic mastocytosis, the administration of rupatadine for 28 days was associated with a 16.1% reduction ($p = 0.004$) in the mean

ItchyQoL total score and 30.3% reduction ($p = 0.001$) in pruritus.

Comparison of the therapeutic efficacy of cromolyn sodium with that of combined chlorpheniramine and cimetidine in systemic mastocytosis: results of a double-blind clinical trial

Frieri M, Alling DW, Metcalfe DD. Am J Med 1985; 78: 9–14.

Five of six patients with systemic mastocytosis had less pruritus and four of six had less urticaria while receiving chlorpheniramine and cimetidine. There was no beneficial effect in those receiving disodium cromoglycate.

Oral disodium cromoglycate in the treatment of systemic mastocytosis

Soter NA, Austen KF, Wasserman SI. N Engl J Med 1979; 301: 465–9.

In a double-blind, crossover study in five patients with systemic mastocytosis and urticaria pigmentosa, in 15 of 18 trials oral disodium cromoglycate ameliorated pruritus and whealing.

Urticaria pigmentosa: clinical picture and response to oral disodium cromoglycate

Czarnetzki BM, Behrendt H. Br J Dermatol 1981; 105: 563–7.

In a blind, crossover trial, 3 children and 10 adults with urticarial pigmentosa were treated with oral disodium cromoglycate or placebo for 1 month, respectively. Relief of pruritus was observed in 67.7% of children and in 70% of adults.

Oral and topical sodium cromoglycate in the treatment of diffuse cutaneous mastocytosis in an infant

Edwards AM, Čapková Š. BMJ Case Reports 2011; 2011:

<http://dx.doi.org/10.1136/bar.02.2011.3910>.

In a single infant with diffuse cutaneous mastocytosis, there was improvement in pruritus, whealing, and flushing after the administration of oral disodium cromoglycate and topical 4% sodium cromoglycate emulsion.

Second-Line Therapies

• Topical glucocorticoid with plastic-film occlusion	C
• NB-UVB phototherapy	D
• Oral PUVA photochemotherapy	D
• Psoralen baths plus UVA photochemotherapy	D
• UVA1 phototherapy	D

Urticaria pigmentosa: systemic evaluation and successful treatment with topical steroids

Guzzo C, Lavker R, Roberts LJ II, Fox K, Schechter N, Lazarus G. Arch Dermatol 1991; 127: 191–6.

In seven of nine adult patients with urticaria pigmentosa, the topical application of betamethasone dipropionate ointment 0.05% under occlusion overnight to one half of the body for 6 weeks was associated with resolution of the lesions, with a maximum response within 3 to 12 weeks after the cessation of treatment. Lesions began to recur between 6 and 9 months after completing therapy. Retreatment for 6 months followed by once-weekly application of betamethasone dipropionate ointment under occlusion kept the patients clear of lesions, with the longest follow-up time being 2.5 years.

The appropriate method for using topical glucocorticoids in patients with urticaria pigmentosa needs to be determined in controlled trials.

Topical corticosteroids versus “wait and see” in the management of solitary mastocytoma in pediatric patients: a long-term follow-up

Patrizi A, Tabanelli M, Neri I, Viridi A. Dermatol Ther 2015; 28: 57–61.

In 130 patients with mastocytomas, 62 were treated with clobetasol cream, and 68 were untreated. A retrospective analysis showed no statistical differences between the two groups in the number of resolved or partially improved subjects. Complete remission occurred in an average of 16.4 months with treatment and 37.5 months without treatment. Average follow-up time was 56.3 months, with a range of 4 to 142 months.

Although the resolution of mastocytomas may occur with or without treatment, the time to resolution is faster with treatment using topical

glucocorticoids, which are effective and safe considering the long time for resolution.

Cutaneous mastocytosis: successful treatment with narrowband ultraviolet B phototherapy

Prignano F, Troiano M, Lotti T. Clin Exp Dermatol 2010; 35: 914–5.

In seven adult patients with urticaria pigmentosa, the pruritus was reduced after three cycles of 12 treatments with narrowband UVB phototherapy.

Indolent systemic mastocytosis treated with narrow-band UVB phototherapy: study of five cases

Brazzelli V, Grasso V, Marina G, Barbaccia V, Merante S, Bouer E, et al. J Eur Acad Dermatol Venereol 2012; 26: 465–9.

In five adult patients with indolent systemic mastocytosis, the pruritus was controlled and urticaria pigmentosa resolved after a median of 3.5 months of therapy. At a 6-month follow-up evaluation, there was no relapse of the pruritus or urticaria pigmentosa.

Due to its excellent side effect profile, NB-UVB phototherapy is preferred to PUVA photochemotherapy or UVA1 phototherapy.

Short- and long-term effectiveness of oral and bath PUVA therapy in urticaria pigmentosa and systemic mastocytosis

Godt O, Proksch E, Streit V, Christophers E. Dermatology 1997; 195: 35–9.

In 20 patients with urticaria pigmentosa treated with PUVA photochemotherapy, improvement in pruritus was seen in 8 of 15 patients. Darier sign was suppressed in 7 and reduced in 8 patients. There was follow-up for 18 years; 25% showed improvement for more than 5 years. Bath PUVA photochemotherapy with 8-methoxypsoralen was without effect. The success of PUVA photochemotherapy lasted from only a few weeks to more than 10 years.

Photochemotherapy of dominant, diffuse, cutaneous mastocytosis

Smith ML, Orton PW, Chu H, Weston WL. Pediatr Dermatol 1990; 7: 251–5.

In three infants and one child with diffuse cutaneous mastocytosis treated with oral PUVA photochemotherapy twice weekly for 3 to 5

months, there was reduced pruritus, reduced blister formation, and a less thick skin, with persistence of dermographism.

Medium- versus high-dose ultraviolet A1 therapy for urticaria pigmentosa: a pilot study

Gobello T, Mazzanti C, Sordi D, Annessi G, Abeni D, Chinni LM, et al. J Am Acad Dermatol 2003; 49: 679–84.

In 12 patients with urticaria pigmentosa, treatment with both medium-dose UVA1 (60 J/cm²) for 15 days and high-dose UVA1 (130 J/cm²) for 10 days was associated with less pruritus, with a decrease in the number of mast cells and a change in the number of lesions over a 6-month period.

The appropriate method and schedules for the use of oral PUVA photochemotherapy, UVA1 phototherapy, and even narrowband UVB phototherapy need to be determined by controlled trials.

Third-Line Therapies

• Interferon- α	D
• Topical calcineurin inhibitors	E
• Leukotriene receptor inhibitors	E
• Thalidomide	E
• Surgical excision	E
• Flashlamp-pumped pulsed dye and Nd:YAG lasers	E
• Electron beam radiation	E
• Tyrosine kinase inhibitors	B
• Cladribine	B
• Omalizumab	E

Treatment of urticaria pigmentosa using interferon alpha

Kolde G, Sunderkötter C, Luger TA. Br J Dermatol 1995; 133: 91–4.

Six adult patients with urticaria pigmentosa, were treated with subcutaneous interferon-alpha started at a daily dose of 0.5×10^6 U, increasing to 5×10^6 U within 10 days. This dose was given five times a week for 6 to 20 weeks then, reduced to three injections a week for 6 to 38 weeks. There was marked improvement of pruritus and whealing and Darier sign became negative. There was no reduction in the number or appearance of the macular and papular skin lesions or in the number or structural organization of the lesional mast cells in light or electron microscopic studies.

Cutaneous mastocytosis: two pediatric patients treated with topical pimecrolimus

Correia O, Duarte AF, Quirino P, Azevedo R, Delgado L. Dermatol Online J 2010; 16: 8.

In two children, 14 to 26 months, with a mastocytoma and in four children, 7 to 16 months, with urticaria pigmentosa, pimecrolimus cream was applied twice daily, and substantial improvement was noted within 3 months.

Leukotriene-receptor inhibition for the treatment of systemic mastocytosis

Tolar J, Tope WD, Neglia JP. N Engl J Med 2004; 350: 735–6.

In a 2-month-old boy with systemic mastocytosis and skin lesions, wheezing, and hepatomegaly, when montelukast 0.25 mg/kg twice daily was not given, wheezing and cutaneous vesicles reappeared and subsided when the drug was readministered.

The leukotriene-receptor inhibitors should be evaluated in mastocytosis in a controlled trial.

Thalidomide in systemic mastocytosis: results from an open-label, multicenter, phase II study

Gruson B, Lortholary O, Canioni D, Chandesris O, Lanterne F, Bruner J, et al. Br J Hematol 2013; 161: 434–42.

In a prospective, open-label, multicenter study on 19 patients with systemic mastocytosis, 14 of whom had urticaria pigmentosa and 1 of whom had diffuse cutaneous mastocytosis, thalidomide was used for 6 months. Of the patients with skin lesions or symptoms, the overall response rate was 61%, with improvement or disappearance of pruritus in 64%.

Solitary mastocytoma in an adult: treatment by excision

Ashinoff R, Soter NA, Freedberg IM. J Dermatol Surg Oncol 1993; 19: 487–8.

In a 33-year-old woman, a solitary mastocytoma was excised.

Treatment of an unusual solitary mast cell lesion with the pulsed dye laser resulting in cosmetic improvement and reduction in the degree of urticarial reaction

Rose RF, Daly BM, Sheehan-Dave R. Dermatol Surg 2007; 31: 851–3.

In a 12-year-old girl with a solitary mast cell lesion with features of solitary mastocytoma and telangiectasia macularis eruptiva perstans treated with a 585-nm pulsed dye laser, there were cosmetic improvement and reduction in the severity of wheals after six treatments.

The treatment of urticaria pigmentosa with the frequency-doubled Q-switch ND-YAG laser

Bedlow AJ, Gharrie S, Harland CC. J Cutan Laser Ther 2000; 2: 45–7.

In a 30-year-old woman with urticaria pigmentosa treated with a frequency-doubled Q-switched Nd:YAG laser, there was initial improvement in the clinical appearance, but the lesions recurred after 9 months.

The cosmetic treatment of urticaria pigmentosa with Nd-YAG laser at 532 nanometers

Resh B, Jones E, Glaser DA. Cosmet Dermatol 2005; 4: 78–82.

In a 19-year-old man with urticaria pigmentosa treated with a 532-nm diode-pumped Nd:YAG laser there was a reduction in the number of lesions.

The efficacy of lasers in the treatment of various forms of cutaneous skin lesions of mastocytosis remains unknown.

Complete response after imatinib mesylate therapy in a patient with well-differentiated systemic mastocytosis

Alvarez-Twose J, González P, Morgado JM, Jara-Acevedo M, Sánchez-Muñoz L, Matito A, et al. J Clin Oncol 2012; 30:e126–9.

In a 65-year-old man with well-differentiated systemic mastocytosis and urticaria pigmentosa, imatinib mesylate, a tyrosine kinase inhibitor, was administered and improvement of the skin lesions was noted at 8 months, with total remission at 18 months when imatinib

mesylate was discontinued. Eight months after discontinuing the treatment, the skin lesions remained in remission.

Imatinib mesylate in the treatment of diffuse cutaneous mastocytosis

Morren M-A, Hoppé A, Renard M, Rychter MD, Uyttebroeck A, Dubreuil P, et al. *J Pediatr* 2013; 162: 205–7.

In a 3-month-old girl and in an 11-month-old girl with diffuse cutaneous mastocytosis and an activating KIT mutation in exon 8 (p. Asp 419 del) in the skin lesions, with the administration of imatinib mesylate for 9 months and 1 year, respectively, there were no relapses with a 2-year and 6-month follow-up, respectively.

Masitinib for the treatment of systemic and cutaneous mastocytosis with handicap: a phase 2a study

Paul C, Sans B, Suarez F, Casassus P, Barete S, Lanternier F, et al. *Am J Hematol* 2010; 85: 921–5.

In a multicenter, open-label trial in 7 patients with cutaneous mastocytosis and in 18 patients with systemic mastocytosis, the administration of masitinib mesylate, a tyrosine kinase inhibitor, resulted in a reduction of mast cells in skin biopsy specimens in 7 of 14 patients and a decrease in pruritus and flushing in 10 of 25 patients.

Cladribine therapy for systemic mastocytosis

Kluin-Nelemans HC, Oldhoff JM, van Doormaal JJ, van't Wout JW, Verhoef G, Gerrits WBJ, et al. *Blood* 2003; 102: 4270–6.

In each of seven patients with systemic mastocytosis and urticaria pigmentosa treated with cladribine, which is a synthetic purine analog cytoreductive agent, there was a reduction in the number of skin lesions to near disappearance and a reduction in mast cells in skin biopsy specimens.

Long-term efficacy and safety of cladribine (2-CdA) in adult patients with mastocytosis

Barete S, Lortholary O, Damaj G, Hirsh I, Chandesris MO, Elle C, et al. *Blood* 2015; 126: 1009–16.

In a nationwide retrospective study in France over one decade in 68 adult patients with various types of systemic mastocytosis who were treated with cladribine, those with urticaria pigmentosa showed

improvement in the skin with a decrease in the number of mast cells in skin biopsy specimens.

Successful treatment of cutaneous mastocytosis and Ménière disease with anti-IgE therapy

Siebenhaar F, Kühn W, Zuberbier T, Maurer M. J Allergy Clin Immunol 2007; 120: 213–5.

In a 56-year-old woman with cutaneous mastocytosis, described as red-brown macules and papules with an increase in mast cells in a skin biopsy specimen, treatment with omalizumab controlled wheal formation and pruritus, although the skin lesions persisted.

Cutaneous and gastrointestinal symptoms in two patients with systemic mastocytosis successfully treated with omalizumab

Lieberoth S, Thomsen SF. Case Rep Med 2015; 2015: 903541.

In a 48-year-old woman and in a 57-year-old man with systemic mastocytosis and severe pruritus, the administration of omalizumab was associated with a reduction in pruritus.

Tyrosine kinase inhibitors, cytoreductive agents, and omalizumab have been used in patients with systemic mastocytosis, with improvement of the skin symptoms in some patients. The use of these therapeutic agents in extensive cutaneous mastocytosis without systemic disease warrants further investigation.

Melasma

Stephanie Ogden, and Christopher E.M. Griffiths

Melasma is an acquired hypermelanosis that most commonly affects females of childbearing age, although males may also be affected. The condition can be classified according to the pattern of facial involvement, which includes centrofacial (forehead, cheeks, chin, and upper lip), malar, and mandibular. Less frequently the neck, arms, and chest may be affected. Melasma is more prevalent in individuals with Fitzpatrick skin types III and above and can have a significant psychosocial impact.

Three histologic subtypes of melasma exist—epidermal, dermal, and mixed—which may be differentiated by the use of a Wood lamp, where epidermal melasma shows enhanced contrast and dermal melasma less contrast. More recently, in vivo reflectance confocal

microscopy has been studied as a noninvasive method of evaluating melasma. Histologic features of melasma include increased epidermal and dermal melanin, solar elastosis, damage to the basement membrane, increased vascularity, and increased numbers of dermal mast cells and CD4+ T cells. Epidermal melasma is the most responsive to treatment.

The pathogenesis of melasma is not fully understood; however, hormonal factors, in particular pregnancy and the use of oral contraceptives, are the most common precipitants. Exposure to ultraviolet (UV) radiation both precipitates and exacerbates. Other etiologic factors include phototoxic medications, genetic predisposition, and thyroid disease.

Management Strategy

Melasma is often difficult to treat due to the recalcitrant and recurrent nature of the condition and the risk of postinflammatory hyperpigmentation associated with some treatments, particularly in individuals with darker skin. Pregnancy-induced melasma may resolve spontaneously postpartum, and females taking the oral contraceptive pill may be advised to change to *an alternative form of contraception*.

Sun exposure increases melanin production and may exacerbate melasma; therefore all patients should receive sun protection advice and use a *high-factor broad-spectrum sunscreen with good protection against UVA*. Recent evidence suggests that *sunscreen with protection against visible light* may provide additional benefit. Patients may also wish to use *camouflage makeup*.

Current treatment options include *topical depigmenting agents, chemical peels, laser therapies, and tranexamic acid*. The response to monotherapy is often limited, and therefore a combination of treatments may optimize outcome. Commonly used treatments include 2% to 5% hydroquinone, tretinoin, triple combination creams (containing hydroquinone, tretinoin, and fluocinolone), and azelaic acid. Glycolic acid is the most commonly reported peeling agent and may be used as an adjunct to topical depigmenting agents. The results of laser therapies are mixed, and treatment carries a significant risk of relapse and postinflammatory hyperpigmentation depending on the type of laser used.

Specific Investigation

- Thyroid function tests

Evaluation of autoimmune thyroid disease in melasma

Rostami Mogaddam M, Iranparvar Alamdari M, Maleki N, Safavi Ardabili N, Abedkouhi S. J Cosmet Dermatol 2015; 14: 167–71.

The prevalence of thyroid abnormalities in 70 nonpregnant females with melasma compared with 70 age-matched controls was 18.5% (15.7% positive anti-thyroid peroxidase antibodies) versus 4.3% (5.7% positive anti-thyroid peroxidase antibodies).

First-Line Therapies

• Triple combination cream	A
• Hydroquinone	A
• Tretinoin	A
• Sunscreen	A

Systematic review of randomized controlled trials on interventions for melasma: an abridged Cochrane Review

Jutley GS, Rajaratnam R, Halpern J, Salim A, Emmett C. J Am Acad Dermatol 2014; 70: 369–73.

This review included 20 studies and concluded that triple combination cream was more effective than hydroquinone or any agent in dual combination. Azelaic acid (20%) was superior to 2% hydroquinone in lightening melasma, and tretinoin led to greater objective improvement in melasma than placebo.

Efficacy and safety of a new triple-combination agent for the

treatment of facial melasma

Taylor SC, Torok H, Jones T. *Cutis* 2003; 72: 67–72.

Two multicenter, randomized studies compared a formulation containing tretinoin 0.05%, hydroquinone 4%, and fluocinolone acetonide 0.01% with the three possible dual combinations of the three agents in 641 patients with melasma (Fitzpatrick skin types I–IV). The triple combination formulation was significantly more effective than any of the dual combinations. At week 8 a 75% reduction in melasma/pigmentation was observed in more than 70% of patients treated, compared with 30% in patients using dual therapy.

Commonly reported adverse effects with triple combination cream include mild erythema, burning, and peeling.

A histologic examination for skin atrophy after 6 months of treatment with fluocinolone acetonide 0.01%, hydroquinone 4%, and tretinoin 0.05% cream

Bhawan J, Grimes P, Pandya AG, Keady M, Byers HR, Guevara I, et al. *Am J Dermatopathol* 2009; 31: 794–8.

This study found no evidence of clinical or histologic atrophy in 30 melasma patients after daily use of triple combination cream for 24 weeks.

Topical tretinoin (retinoic acid) improves melasma. A vehicle-controlled, clinical trial

Griffiths CEM, Finkel LJ, Ditre CM, Hamilton TA, Ellis CN, Voorhees JJ. *Br J Dermatol* 1993; 129: 415–21.

A study of 0.1% tretinoin once daily in 38 Caucasian women for 40 weeks found that 68% of tretinoin-treated patients were improved or much improved, compared with only 5% in the vehicle-treated group. Erythema and desquamation were more common in the tretinoin group.

The efficacy of a broad spectrum sunscreen in the treatment of melasma

Vasquez M, Sanchez JL. *Cutis* 1983; 92: 95–6.

Broad-spectrum sunscreen compared with vehicle used alongside hydroquinone led to improvement in 96% of subjects compared with 81% of those using vehicle.

Near-visible light and UV photoprotection in the treatment of melasma: a double-blind randomized trial

Castanedo-Cazares JP, Hernandez-Blanco D, Carlos-Ortega B, Fuentes-Ahumada C, Torres-Alvarez B. Photodermatol Photoimmunol Photomed 2014; 30: 35–42.

A randomized study of 68 patients with melasma treated with 4% hydroquinone and sunscreen with either broad-spectrum UV protection alone or with iron oxide as a visible light-absorbing pigment. Patients using sunscreen with additional protection against visible light experienced significantly greater improvement in melasma.

The vast majority of recent clinical trials for melasma treatments include regular use of a high-factor sunscreen as part of the regimen.

Second-Line Therapies

• Azelaic acid	A
• Glycolic acid peels	A
• Adapalene	A

The treatment of melasma: 20% azelaic acid versus 4% hydroquinone cream

Balina LM, Graupe K. Int J Dermatol 1991; 30: 893–5.

A double-blind, randomized study of over 300 women. After the 24-week treatment period, 65% of azelaic acid-treated patients had good or excellent results. No significant treatment differences were observed between azelaic acid- and hydroquinone-treated patients.

Glycolic acid peels/azelaic acid 20% cream combination and low potency triple combination lead to similar reduction in melasma severity in ethnic skin: results of a randomized controlled study

Mahajan R, Kanwar AJ, Parsad D, Kumaran MS, Sharma R. Indian J Dermatol 2015; 60: 147–52.

A 12-week randomized study of 40 patients treated with either low-potency triple combination cream (hydroquinone 2%, tretinoin 0.05%, fluocinolone 0.01%) or glycolic acid peels (starting at 20% and gradually increasing to 70% repeated at 2-week intervals) in combination with 20% azelaic acid cream at night (apart from 2 days before and after peels).

Efficacy and safety of serial glycolic acid peels and a topical regimen in the treatment of recalcitrant melasma

Erbil H, Sezer E, Tastan B, Arca E, Kurumlu Z. J Dermatol 2007; 34: 25–30.

Twenty-eight patients were randomized to receive eight peels, starting at 20% glycolic acid and increasing gradually to 70% on alternate weeks combined with azelaic acid 20% cream and adapalene 0.1% applied at night, or the topical agents alone, over a 20-week treatment period. A significant improvement in the melasma area and severity index (MASI) was seen in both groups at 20 weeks, although there was greater improvement in the chemical peel group.

Use of superficial peels may speed and enhance the response to topical agents. Other peeling agents that have been used in the treatment of melasma include salicylic acid, tretinoin 1%, Jessner solution, and trichloroacetic acid.

Adapalene in the treatment of melasma: a preliminary report

Dogra S, Kanwar AJ, Parasad D. J Dermatol 2002; 29: 539–40.

A randomized split-face study of 30 women comparing adapalene 0.1% and tretinoin 0.05% for 14 weeks. Both retinoids produced a similar significant improvement in melasma. Adapalene was better tolerated.

Third-Line Therapies

• Niacinamide	A
• Kojic acid	A
• Lignin peroxidase	A
• Rucinol	A
• Topical tranexamic acid	A
• Laser and intense pulsed light (IPL)	B
• Oral tranexamic acid	B

A double-blind, randomized clinical trial of niacinamide 4% versus hydroquinone 4% in the treatment of melasma

Navarrete-Solis J, Castanedo-Cazares J, Torres-Alvarez B, Oros-Ovalle C, Fuentes-Ahumada C, Gonzalez FJ, et al. *Dermatol Res Pract* 2011; 2011: 379173.

Twenty-seven patients with Fitzpatrick skin types IV or V were enrolled in this 8-week study. The MASI scores improved from 4 to 1.2 in the hydroquinone-treated skin and from 3.7 to 1.4 in the niacinamide-treated skin.

Kojic acid vis-à-vis its combinations with hydroquinone and betamethasone valerate in melasma: a randomized, single blind, comparative study of efficacy and safety

Deo KS, Dash KN, Sharma YK, Virmani NC, Oberai C. *Indian J Dermatol* 2013; 58: 281–5.

A single-blind, randomized study of 80 patients treated with either kojic acid 1% cream; kojic acid 1% and hydroquinone 2% cream; kojic acid 1% and betamethasone valerate 0.1% cream; or kojic acid 1%, hydroquinone 2%, and betamethasone valerate 0.1% cream. All groups demonstrated improvement in MASI score; however, the greatest response was seen with kojic acid used in combination with hydroquinone.

Kojic acid is derived from fungi and is considered to have high sensitizing

potential.

A split-face evaluation of a novel pigment-lightening agent compared with no treatment and hydroquinone

Draelos ZD. J Am Acad Dermatol 2015; 72: 105–7.

In this investigator-blind 12-week study of 60 women with Fitzpatrick skin types I–IV, twice-daily topical therapy with lignin peroxidase was compared with either no treatment or 4% hydroquinone. Significant improvement in MASI scores was noted with lignin peroxidase, with comparable results to that seen with hydroquinone.

Lignin peroxidase is an enzyme derived from a tree fungus that breaks down melanin. Further work to evaluate this treatment is warranted.

Evaluation of efficacy and safety of rucinol serum in patients with melasma: a randomized controlled trial

Khemis A, Kaiafa A, Queille-Roussel C, Duteil L, Ortonne JP. Br J Dermatol 2007; 156: 997–1004.

A double-blind, randomized, split-face study of rucinol 0.3% (4-n-butylresorcinol) serum or vehicle for 12 weeks in 28 women, which revealed a significant improvement in clinical pigmentation score in rucinol-treated compared with vehicle-treated skin. The treatment was well tolerated.

Efficacy and safety of liposome-encapsulated 4-n-butyl resorcinol 0.1% cream for the treatment of melasma: a randomized controlled split-face trial

Huh SY, Shin J, Na J, Huh C, Youn S, Park K. J Dermatol 2010; 37: 311–5.

This study of 23 Korean women with melasma found a significantly greater improvement in the melanin index in patients receiving the active treatment, although the reduction was modest.

Rucinol is a resorcinol derivative that inhibits tyrosinase and tyrosinase-related protein-1 activity in vitro.

Topical tranexamic acid as a promising treatment for melasma

Ebrahimi B, Naeini FF. J Res Med Sci 2014; 19: 753–7.

A randomized, double-blind, split-face study of 3% tranexamic acid solution compared with 3% hydroquinone and 0.01% dexamethasone,

both applied twice daily for 12 weeks. Thirty-nine patients with epidermal melasma completed the study with comparable significant improvements in MASI scores.

Tranexamic acid is thought to reduce melanin synthesis through inhibition of the plasminogen/plasmin pathway. One split-face, vehicle-controlled study of a liposome gel formulation of tranexamic acid reported no significant difference compared with vehicle in terms of change in MASI. More studies to determine the long-term effects, optimum formulation, and effects of combination of topical tranexamic acid with established treatments are required.

Nonablative 1550-nm fractional laser therapy versus triple topical therapy for the treatment of melasma: a randomized controlled pilot study

Kroon MW, Wind BS, Beek JF, van der Veen JP, Nieuweboer-Krobotov L, Bos J, et al. J Am Acad Dermatol 2011; 64: 516–23.

This observer-blinded study of 20 women with melasma compared triple combination cream with four sessions of nonablative 1550-nm fractional laser therapy over an 8-week period. Both treatments resulted in a significant improvement in melasma, although there was evidence of recurrence in half the patients in each group at 6-month follow-up.

The results of open-label studies of fractional photothermolysis for melasma are variable. A number of uncontrolled studies have reported a significant incidence of postinflammatory hyperpigmentation. The treatment has little or no “downtime.” One study found no additional benefit of fractional photothermolysis plus Q-switched neodymium doped yttrium-aluminum-garnet (Nd:YAG) laser treatment versus Nd:YAG alone.

A comparison of low-fluence 1064-nm Q-switched Nd:YAG laser with topical 20% azelaic acid cream and their combination in melasma in Indian patients

Bansal C, Naik H, Kar HK, Chauhan A. J Cutan Aesthet Surg 2012; 5: 266–72.

Sixty patients (Fitzpatrick skin type III–V) were randomized to receive treatment with Nd:YAG laser (0.5–1 J/cm²) alone or in combination with 20% azelaic acid twice daily. Combination therapy was more effective in improving MASI score at 12 weeks.

Higher energy settings have been associated with an increased risk of postinflammatory hyperpigmentation. There are reports of mottled

hypopigmentation after use of this laser, which can be long lasting; furthermore recurrence of melasma or rebound hyperpigmentation after treatment is common. Laser therapy may be more effective when combined with other topical treatments such as triple combination cream.

Single-session intense pulsed light combined with stable fixed-dose triple combination topical therapy for the treatment of refractory melasma

Figueiredo Souza L, Trancoso Souza S. *Dermatol Ther* 2012; 25: 477–80.

A randomized study of 62 patients (Fitzpatrick skin types II–V) who received either a single session of IPL followed by triple combination cream or triple combination cream alone. Assessment at 6 months demonstrated a significantly greater improvement in melasma in the IPL-treated group. Three patients developed postinflammatory hyperpigmentation in the IPL group.

Melasma-like hyperpigmentation has been reported in patients treated with IPL. Further controlled trials with longer follow-up are required to determine the safety of IPL for melasma, as well as the risk of recurrence.

Oral tranexamic acid with fluocinolone-based triple combination cream versus fluocinolone-based triple combination cream alone in melasma: an open labeled randomized comparative trial

Padhi T, Pradhan S. *Indian J Dermatol*; 2015; 60: 520.

Forty patients were included in this randomized, open-label study, which compared oral tranexamic acid 250 mg twice daily and triple combination cream daily with the cream alone. There was a greater improvement in MASI scores at 8 weeks in the tranexamic acid-treated group. No recurrences were noted at 6-month follow-up.

Tranexamic acid is contraindicated in individuals with a history of thromboembolic disease. Further controlled studies are required to determine safety, efficacy, and optimal dosing regimens.

Cysteamine 5% cream and topical undecylenoyl phenylalanine 2% have been reported to be effective in treating melasma in single short-term, placebo-controlled studies; further longer-term studies comparing these treatments with established treatments such as hydroquinone/ triple combination cream are warranted.

Merkel cell carcinoma

Maryam Liaqat, and Warren R. Heymann

Merkel cell carcinoma (MCC) is a rare, cutaneous, neuroendocrine carcinoma with aggressive clinical behavior initially described by Toker in 1972. Classically presenting as a firm, dome-shaped, red to purple nodule, MCC typically affects older individuals, with the median patient age being 69 years. Immunosuppressive conditions such as chronic lymphocytic leukemia, human immunodeficiency virus, and solid organ transplantation have been linked to an

increased risk of developing MCC. In terms of the pathogenesis of MCC, evidence exists for both infectious and environmental factors. Support for viral-promoted oncogenesis came with the discovery in 2008 of the Merkel cell polyomavirus. Ultraviolet (UV) radiation has also been described as a risk factor for the development of MCC, as most of these tumors develop at sites of sun damage with UV-associated cutaneous malignancies. The most common location is the head and neck region followed by the trunk. There is a high mortality rate associated with MCC, reported to range from 33% to 46%. Rarely, MCC may display spontaneous regression.

Management Strategy

Given the rarity of this malignancy, randomized controlled trials for therapies are lacking. As such, much of the data regarding the success of treatment modalities such as surgery, radiation, and chemotherapy stem from case series or retrospective analyses of patient data. An algorithmic approach to treatment has been put forth by the National Comprehensive Cancer Network (NCCN).

Imaging is employed for the initial workup and staging (as clinically indicated) to detect regional or distant metastases. This may be performed with either computed tomography (CT), magnetic resonance imaging (MRI), or FDG/somatostatin receptor positron emission tomography–CT (PET-CT), although studies have not shown a convincing advantage for functional imaging modalities.

Surgical removal of the primary tumor is an important component of any treatment strategy, either with standard wide local excision or Mohs micrographic surgery. In addition to excision of the primary tumor, sentinel lymph node biopsy (SLNB) is often recommended, if feasible, given the tendency of the tumor to metastasize. Evidence of clinically positive lymphadenopathy at the time of presentation will often prompt lymphadenectomy.

There are no approved therapies for advanced disease. Radiation may be used adjunctively for disease control to the primary site as well as the draining lymph node basin. Not all studies have shown a statistically significant benefit with radiation therapy. Moreover, recurrences may respond less well to radiation therapy. Chemotherapy is sometimes employed, though less evidence supports its use. Isolated limb perfusion or infusion has been used successfully for in-transit metastases. Finally, recent use of checkpoint

inhibitors against programmed death-ligand 1 in advanced disease has shown positive results.

Specific Investigations

- Diagnostic imaging
- Prognostic serology
- Sentinel lymph node biopsy

Complete spontaneous regression of Merkel cell carcinoma (1986–2016): a 30 year perspective

Walsh NM. J Cutan Pathol 2016; 43: 1150–4.

A review of spontaneous regression of MCC, which usually results in a cure. The author speculates on the role of the MCC polyomavirus in the process.

Somatostatin receptor positron emission tomography/computed tomography imaging in Merkel cell carcinoma

Sollini M, Taralli S, Millela M, Erba PA, Rubagotti S, Fraternali A, et al. J Eur Acad Dermatol Venereol 2016; 30: 1507–11.

A retrospective study of 23 consecutive MCC patients who underwent a somatostatin receptor PET-CT imaging. PET-CT was used to detect primary tumor site (4/23) or to stage (8/23) or restage (11/23) patients. Sensitivity, specificity, and diagnostic accuracy of PET-CT were 92%, 73%, and 83%, respectively.

Somatostatin PET-CT has high diagnostic performance, resulting in changing the management of 7/23 patients. However, it failed to identify the site of unknown primary MCC similarly to conventional imaging.

Interest of (18)F-FDG PET-CT scanning for staging and management of Merkel cell carcinoma: a retrospective study of 15 patients

Maury G, Dereure O, Du-Thanh A, Mariano-Goulart D, Guillot B. J Eur Acad Dermatol Venereol 2011; 25: 1420–7.

This retrospective study of 15 patients compared clinical staging with (18)FDG PET-CT as well as conventional CT. Investigators found that FDG PET-CT imaging did not change disease staging and/or management based on a combination of clinical examination, SLNB,

and conventional CT. Conventional CT and FDG PET-CT demonstrated identical sensitivity and specificity in this small patient cohort.

These results support data of other studies that have shown similar sensitivities when comparing functional and anatomic imaging modalities.

Prognostic value of antibodies to Merkel cell polyomavirus T antigens and VP1 protein in patients with Merkel cell carcinoma

Samimi M, Molet L, Fleury M, Laude H, Carlotti A, Gardair C, et al. Br J Dermatol 2016; 174: 715–6.

A retrospective and prospective trial at 11 French hospitals where 143 samples were included in the study. Antibodies against T antigens were associated with disease burden and therefore thought to be a useful marker of disease recurrence or progression when detected >12 months after diagnosis. In contrast, antibodies to major capsid VP1 protein have a favorable prognostic value when detected at high levels at baseline.

Absolute lymphocyte count: a potential prognostic factor for Merkel cell carcinoma

Johnson ME, Zhu F, Li T, Wu H, Galloway TJ, Farma JM, et al. J Am Acad Dermatol 2014; 70: 1028–35.

At a single institution, a retrospective study of 64 patients with MCC complete blood count was obtained in the month before definitive surgery, chemotherapy, or radiation. An absolute lymphocyte count (ALC) of 1.1 k/mm^3 was noted to be associated with overall, but not disease-free, survival. The authors concluded that ALC, a simple test, may provide additional prognostic information.

Sentinel lymph node biopsy in Merkel cell carcinoma: a 15-year institutional experience and statistical analysis of 721 reported cases

Gunaratne DA, Howle JR, Veness MR. Br J Dermatol 2016; 174: 273–81.

A comprehensive literature review of MCC patients undergoing SLNB. SLNBs were taken from 736 regional sites with 29.6% recorded as positive. Distant relapse was noted more commonly with positive SLNB.

Merkel cell carcinoma: value of sentinel lymph-node status and adjuvant radiation therapy

Servy A, Maubec E, Sugier PE, Grange F, Mansard S, Lesimple T, et al. *Ann Oncol* 2016; 27: 914–9.

SLNB positivity was noted in 21 of 87 patients with MCC. Patients with SLNB negativity were noted to have a longer disease-free survival and overall survival in stage I and II disease.

Recurrence and survival in patients undergoing sentinel lymph node biopsy for Merkel cell carcinoma: analysis of 153 patients from a single institution

Fields RC, Busam KJ, Chou JF, Panageas KS, Pulitzer MP, Kraus DH, et al. *Ann Surg Oncol* 2011; 18: 2529–37.

SLNB was positive in 29% of patients with clinically negative nodes in this retrospective review of 153 patients. Primary tumor size and the presence of lymphovascular invasion were associated with sentinel lymph node positivity. The status of the sentinel lymph node was not associated with disease-specific survival or disease recurrence.

Sentinel lymph node biopsy for evaluation and treatment of patients with Merkel cell carcinoma: the Dana-Farber experience and meta-analysis of the literature

Gupta SG, Wang LC, Peñas PF, Gellenthin M, Lee SJ, Nghiem P. *Arch Dermatol* 2006; 142: 685–90.

This study presented a combination of a single-institution retrospective review (30 patients) and literature-based meta-analysis (92 patients) for a total of 122 patients, and it found that SLNBs can detect clinically and radiographically occult disease. CT scans of lymph node basins have a low sensitivity (20%) for detecting both regional and distant metastases. Patients with positive SLNBs were more likely to receive adjuvant therapy and benefit from such therapy (improved relapse-free survival). The median follow-up period of this study of 12 to 15 months did not allow investigators to report disease-specific survival. Instead, only relapse-free survival data were reported.

First-Line Therapies

• Wide surgical excision	C
• Mohs micrographic surgery	C/E

Mohs micrographic surgery for the treatment of Merkel cell carcinoma

Kline L, Coldiron B. *Dermatol Surg* 2016; 42: 945–51.

This study was a retrospective chart review of 22 patients treated with Mohs surgery at a single institution. The recurrence rate was noted to be 5%. Regional lymph node metastasis was 14%, and no distant metastases were reported.

Merkel cell carcinoma. Comparison of Mohs micrographic surgery and wide excision in eighty-six patients

O'Connor WJ, Roenigk RK, Brodland DG. *Dermatol Surg* 1997; 23: 929–33.

Examining 86 patients with MCC in their retrospective review, standard wide local excision was noted to be associated with a high rate of local persistence and regional metastasis (32% and 49%, respectively) compared with Mohs micrographic surgical excision (8.3% for local persistence and 33.3% for regional metastasis). The mean follow-up for patients treated with standard surgical excision was 60 months, whereas the follow-up for those treated with Mohs excision was 36 months. Adjuvant radiation therapy reduces local persistence of tumor and regional metastases in Mohs-treated patients.

This review only included 13 patients who received Mohs excision. In addition, the extended follow-up period for patients treated with standard surgical excision compared with Mohs excision selects for more recurrences and metastases in the former group.

Second-Line Therapies

• Radiation	C
• Chemotherapy and isolated limb perfusion/infusion	C
• Check point inhibitors	E/B

Radiation therapy is associated with improved outcomes in Merkel cell carcinoma

Strom T, Carr M, Zager J, Naghavi A, Smith FO, Cruse CW, et al. Ann Surg Oncol 2016; 23: 3572–8.

This study included 171 patients with nonmetastatic MCC and pathologic nodal evaluation in whom the majority underwent wide local excision. The study demonstrated a higher rate of local control, local regional control, and survival with the use of radiation therapy. Additionally, radiation therapy was beneficial regardless of tumor margin status.

Adjuvant radiation therapy is associated with improved survival in Merkel cell carcinoma of the skin

Mojica P, Smith D, Ellenhorn JD. J Clin Oncol 2007; 25: 1043–7.

This was a retrospective study of 1487 patients who received some form of cancer-directed surgery as part of their treatment. Those who also received adjuvant radiation therapy showed improved median survival compared with those who did not undergo radiation.

Although this study included a large number of patients, the methods and regimens of radiation therapy delivered varied, with some patients receiving external beam radiation therapy and others receiving radioisotopes, implants, or some combination of these.

Adjuvant radiation therapy and chemotherapy in Merkel cell carcinoma: survival analyses of 6908 cases from the National Cancer Database

Bhatia S, Storer BE, Iyer JG, Moshiri A, Parvathaneni U, Byrd D, et al. J Natl Cancer Inst 2016; 108: djw042.

In the largest cohort of MCC patients to date, the authors evaluated the role of adjuvant radiation therapy and chemotherapy in survival. As previously reported, adjuvant radiation therapy was found to improve overall survival in MCC stage I and II disease. However, neither chemotherapy nor radiation therapy resulted in overall

survival for stage III MCC.

Although 6908 MCC patients represents a very large cohort, this is a retrospective, nonrandomized analysis. Additionally, details regarding chemotherapy were lacking in the review.

In-transit Merkel cell carcinoma treated with isolated limb perfusion or isolated limb infusion: a case series of 12 patients

Zeitouni NC, Giordano CN, Kane JM. *Dermatol Surg* 2011; 37: 357–64.

In this series of 12 patients (two from the authors' institution and 10 from the literature), isolated limb infusion was found to be less invasive than isolated limb perfusion. Two patients from the authors' institution were treated with isolated limb infusion, whereas those reported from review of the literature had been treated with isolated limb perfusion. All patients were able to avoid limb amputation. Complete response was seen in 11/12 patients. One patient had a partial response. Mean duration of response was 21.8 months. The mean follow-up period was 25.3 months.

Although both techniques appear to be reasonable options for the treatment of in-transit disease, the inclusion of only two cases of isolated limb infusion compared with 10 cases of isolated limb perfusion makes comparison of their respective efficacies difficult. Both isolated limb infusion and isolated limb perfusion allow for the regional treatment of in-transit or advanced local disease with high-dose chemotherapy while minimizing systemic effects; however, isolated limb infusion is less invasive (percutaneous catheter placement) than isolated limb perfusion. In addition, isolated limb infusion may be performed in areas of prior lymphadenectomy with scarred vessels permitting repeat treatments as needed. Moreover, isolated limb infusion utilizes a low-flow, hypoxic system with subsequently shorter treatment times.

Avelumab in patients with chemotherapy-refractory metastatic Merkel cell carcinoma: a multicentre, single-group, open-label, phase 2 trial

Kaufman H, Russell J, Hamid O, Bhatia S, Terheyden P, D'Angelo SP, et al. *Lancet Oncol* 2016; 17: 1374–85.

An open-label, single-group, international, phase II trial of an anti PD-L1 monoclonal antibody for patients with chemotherapy-refractory stage IV MCC. Eighty-eight patients were enrolled and received one dose of avelumab. Nine percent of patients had a complete response, whereas 23% had a partial response. The

medication was tolerated well, with only five grade 3 treatment-related adverse effects, and there were no grade 4 events or deaths.

PD-L1 expression is noted to be high in the majority of MCCs; therefore use of PD-L1 inhibitors to regulate the immune system interactions appears intuitive. The results of the study are promising, and similar outcomes have been noted with other checkpoint inhibitors. This study included patients previously treated with chemotherapy, suggesting that avelumab has higher efficacy.

PD-1 blockade with pembrolizumab in advanced Merkel-cell carcinoma

Nghiem PT, Bhatia S, Lipson EJ, Kudchadkar RR, Miller N, Annamalai L, et al. N Engl J Med 2016; 374: 2542–52.

A multicenter, phase II, noncontrolled study in patients with advanced MCC with no previous systemic therapy who were treated with pembrolizumab at dose levels approved for melanoma. A total of 26 patients received at least one dose. Pembrolizumab was noted to have an objective response rate of 56%: four patients with a complete response and ten patients with a partial response. Grade 3 or 4 treatment-related adverse events were observed in four of the 26 patients.

Similar to other checkpoint inhibitors, responses to pembrolizumab were observed irrespective of Merkel cell polyomavirus status. Note there were grade 4 treatment-related adverse reactions in this study, one of which was noted to be myocarditis. However, this improved on discontinuation of therapy and initiation of glucocorticoid treatment. Overall, checkpoint blockade may be the best option to treat patients with advanced MCC.

**Methicillin-resistant
Staphylococcus aureus
and Panton–Valentine
leukocidin
Staphylococcus aureus
infections**

Dirk M. Elston

Methicillin- resistant *Staphylococcus aureus* (MRSA) bacteria have developed resistance to beta-lactam antibiotics such as methicillin, dicloxacillin, nafcillin, and oxacillin and the cephalosporins through horizontal gene transfer and natural selection. Although not necessarily more virulent than sensitive strains, infection caused by them is more difficult to treat due to their resistance to standard antibiotics. Although originally described in health care settings (hospitals and care homes), it is now endemic in community as well as livestock settings.

Panton–Valentine leukocidin (PVL) is a toxin that destroys leukocytes and is a virulence factor in some strains of *S. aureus* (SA). Strains of PVL-SA producing a new pattern of disease have emerged in the UK and worldwide. In the UK the genes encoding for PVL are carried by <2% of clinical isolates of *S. aureus* submitted to the National Reference Laboratory, whether methicillin-sensitive *S. aureus* (MSSA) or MRSA. Like other *S. aureus* strains, PVL-SA predominantly causes skin and soft tissue infections (SSTI) but can also cause invasive infections (myositis, osteomyelitis). The most serious of these is a necrotizing hemorrhagic pneumonia with a high mortality, which often follows a “flu-like” illness and may affect otherwise healthy young people in the community. PVL skin infections may be remarkably severe, painful, and recurrent, producing folliculitis, furunculosis cellulitis, and skin necrosis. Transmission has been

associated with family groups, contact sports, gymnasium use, and military camps.

Management Strategy (MRSA)

Health care–type strains of MRSA are associated with sepsis and are common colonists of chronic wounds, where debridement is typically the best strategy. Community-type MRSA infections typically present as an abscess or furunculosis. The most important intervention for an abscess remains surgical drainage. Purulent material can reform rapidly, so a punch or cruciate incision is advised, as it tends to remain open longer to allow adequate drainage. A curette is used to probe the wound and ensure that all pockets of purulent material have been adequately drained. Irrigation can be helpful, but packing is discouraged, as purulent material often reforms behind the packing material. Evidence suggests that antibiotics are often unnecessary if an abscess is adequately drained. There are obvious reasons to avoid antibiotics when they are not needed, including the risk of Stevens–Johnson syndrome, antibiotic-associated diarrhea, and selection of resistant strains.

Patients with significant surrounding cellulitis, refractory infection, or systemic manifestations may require antibiotic therapy. Most community-associated (CA) MRSA strains are sensitive to trimethoprim–sulfamethoxazole. Most strains are also sensitive to doxycycline and minocycline, but doxycycline does not penetrate well into the nares. Clindamycin resistance is emerging in many communities. For serious infections, therapy should be guided by culture and sensitivity. Vancomycin, linezolid, dalbavancin, telavancin, and daptomycin are often effective. Rifampin improves the intracellular killing of bacteria by vancomycin. Quinupristin–dalfopristin and tigecycline may also be effective, but quinupristin–dalfopristin, like daptomycin, may not penetrate reliably into pulmonary tissue, and tigecycline has a significant incidence of nausea. Ceftobiprole and oritavancin appear promising.

Spread occurs through skin-to-skin contact and via fomites. Decolonization may be indicated for prevention of recurrence or prevention of serious invasive disease in close contacts. The most effective decolonization regimens address the nares, intertriginous, and anogenital sites, as well as eczematous skin. In some patients, gut colonization may also be an issue.

Specific Investigations

Cultures should be obtained from the contents of purulent infections and resistant infections. New molecular diagnostic tests are being developed to screen for MRSA and identify genes associated with resistance.

Screening for mupirocin resistance in *Staphylococcus*

Sanju AJ, Kopula SS, Palraj KK. J Clin Diagn Res 2015; 9: DC09–10.

In a study of 100 stains of *Staphylococcus*, higher levels of resistance were noted by the minimum inhibitory concentration (MIC) method than by the disc diffusion method.

When screening for mupirocin resistance, the disk diffusion method may fail to identify low-level mupirocin resistance.

High vancomycin minimum inhibitory concentration is a predictor of mortality in methicillin-resistant *Staphylococcus aureus* bacteremia

Wi YM, Kim JM, Joo EJ, Ha YE, Kang CI, Ko KS, et al. Int J Antimicrob Agents 2012; 40: 108–13.

A retrospective cohort study of 137 patients with MRSA bacteremia demonstrated a 30-day cumulative survival of 53.8% for patients infected with isolates having an MIC ≥ 1 $\mu\text{g/mL}$ and 79.8% for patients infected with isolates having an MIC < 1 $\mu\text{g/mL}$ (log-rank test, $p=0.026$).

Although data has been mixed, this study suggests early consideration of an alternative agent in seriously ill patients with MRSA bacteremia whose isolate demonstrates high vancomycin MICs.

Epidemiology

Genome-wide association study reveals a locus for nasal carriage of *Staphylococcus aureus* in Danish crossbred pigs

Skallerup P, Espinosa-Gongora C, Jørgensen CB, Guardabassi L, Fredholm M. BMC Vet Res 2015; 11: 290.

Pigs have been identified as a major reservoir of MRSA, and the use of antibiotics in livestock has been associated with transmission of resistant organisms to humans. A single nucleotide polymorphism on

chromosome 12 was found to be associated with nasal carriage of *S. aureus* in pigs, suggesting it may be possible to select pigs genetically resistant to *S. aureus* colonization.

The emerging ST8 methicillin-resistant *Staphylococcus aureus* clone in the community in Japan: associated infections, genetic diversity, and comparative genomics

Iwao Y, Ishii R, Tomita Y, Shibuya Y, Takano T, Hung WC, et al. *Kansenshogaku Zasshi* 2015; Suppl 13: 15–27.

Japanese ST8 CA-MRSA, a new strain with SCCmecIV1, has emerged in Japan. It is associated with SSTIs, colitis, and invasive infections (sepsis, epidural abscesses, and necrotizing pneumonia). It lacks the Panton–Valentine leukocidin phage and arginine catabolic mobile element present in our typical USA300 strain.

This new strain has already spread to Hong Kong and can be expected to appear elsewhere.

Prognosis

Treatment failure outcomes for emergency department patients with skin and soft tissue infections

May LS, Zocchi M, Zatorski C, Jordan JA, Rothman RE, Ware CE, et al. *West J Emerg Med* 2015; 16: 642–52.

In this study of 272 patients, 198 (72.8%) completed 1-week follow-up, and 10.2% of patients reported 1-week treatment failure. The use of packing was associated with a higher risk of treatment failure, and the odds of treatment failure were 66% lower for patients who received antibiotics after incision and drainage.

Data is emerging that the use of packing is associated with treatment failure after drainage of an abscess. Some data suggests that the addition of an antibiotic may be associated with improved outcomes.

Pathogenesis

Skin commensal staphylococci may act as reservoir for fusidic acid resistance genes

Hung WC, Chen HJ, Lin YT, Tsai JC, Chen CW, Lu HH, et al. *PLoS One* 2015; 10: e0143106.

In a study of 59 healthy volunteers, a total of 34 fusidic acid-resistant staphylococcal strains were isolated from 22 individuals. All were coagulase negative, and resistance genes *fusB* or *fusC* were present in *Staphylococcus epidermidis*, *Staphylococcus capitis* subsp. *urealyticus*, *Staphylococcus hominis* subsp. *hominis*, *Staphylococcus warneri*, and *Staphylococcus haemolyticus*.

These findings suggest that the skin commensal staphylococci may act as reservoirs for fusidic acid resistance genes.

First-Line Therapy

Treatment of MRSA abscesses

• Surgical drainage alone	B
• Surgical drainage plus	
trimethoprim–sulfamethoxazole	B
• Minocycline	B
• Doxycycline	B
• Clindamycin	B

Eradication of colonization: nares

• Mupirocin	B
• Tea tree oil	B

Eradication of colonization: skin

• Bleach baths	D
• Chlorhexidine	B
• Triclosan	B
• Tea tree oil soap	B
• Undecylenamidopropyltrimonium methosulfate/phenoxylethanol	C
• Octenidine dihydrochloride	C

Microbiology and initial antibiotic therapy for injection drug users and noninjection drug users with cutaneous abscesses in the era of community-associated methicillin-resistant *Staphylococcus aureus*

Jenkins TC, Knepper BC, Jason Moore S, Saveli CC, Pawlowski SW, Perlman DM, et al. Acad Emerg Med 2015; 22: 993–7.

Injection drug use is a risk factor for abscesses and MRSA infection. In a study of seven academic and community hospitals in Colorado, antibiotic regimens started in the emergency department were compared between injection drug users and noninjection drug users.

Among the 323 patients with cutaneous abscesses, 104 (32%) occurred in injection drug users. Surprisingly, among the 235 cases where at least one microorganism was identified by culture, *S. aureus* was identified less commonly among injection drug users compared with noninjection drug users (55% vs. 75%, $p = 0.003$), with similar patterns observed for MRSA (33% vs. 47%, $p = 0.054$) and MSSA (17% vs. 26%, $p = 0.11$).

Compared with noninjection drug users, cutaneous abscesses in injection drug users were less likely to involve *S. aureus*, including MRSA, and more likely to involve streptococci and anaerobes. Although clindamycin provides coverage against all of these pathogens, trimethoprim–sulfamethoxazole provides inadequate coverage for streptococci and anaerobes. This suggests that the choice of antibiotic should take factors like IV drug abuse into account.

Epidemiology, microbiology, and antibiotic susceptibility patterns of skin and soft tissue infections, Joint Base San Antonio-Lackland, Texas, 2012 to 2014

Fisher A, Webber BJ, Pawlak MT, Johnston L, Tchandja JB, Yun H. MSMR 2015; 22: 2–6.

An outbreak of MRSA infection was reported among military families in San Antonio in 2014. Of the 772 total cases studied, 254 were cultured and 196 resulted in growth of one or more pathogens. MRSA was the most common pathogen ($n = 110$). MSSA ($n = 68$), other gram-positive cocci ($n = 5$), and gram-negative rods ($n = 18$) were also isolated. In vitro activity of commonly used antibiotics against *S. aureus* isolates dropped from the previous surveillance period.

Outbreaks of MRSA infection with decreased antimicrobial susceptibility warrant enhanced local preventive efforts and close adherence to evidence-based treatment algorithms.

Trimethoprim-sulfamethoxazole therapy reduces failure and recurrence in methicillin-resistant *Staphylococcus aureus* skin abscesses after surgical drainage

Holmes L, Ma C, Qiao H, Drabik C, Hurley C, Jones D, et al. J Pediatr 2016; 169: 128–34.

Patients age 3 months to 17 years of age with uncomplicated skin abscess that required surgical drainage were randomized to receive either 3 or 10 days of oral trimethoprim–sulfamethoxazole therapy. Among those with MRSA infection, those treated for only 3 days were more likely to experience treatment failure ($P = 0.03$, rate difference 10.1%, 95% confidence interval [CI], 2.1%–18.2%) and recurrent infection within 1 month ($P = 0.046$, rate difference 10.3%, 95% CI, 0.8%–19.9%).

Although the primary treatment for a MRSA abscess remains thorough drainage, this study and others suggest that antibiotics may reduce the risk of treatment failure and recurrence. A full 10 days of treatment is superior to an abbreviated 3-day course.

Recurrent skin and soft tissue infections in HIV-infected patients during a 5-year period: incidence and risk factors in a retrospective cohort study

Hemmige V, McNulty M, Silverman E, David MZ. BMC Infect Dis 2015; 15: 455.

Risk factors for recurrent infection in a multivariable Cox regression model were nonhepatitis liver disease, the presence of an intravenous catheter, and a history of intravenous drug use.

Highly active antiretroviral therapy (HAART), CD4⁺ count, trimethoprim–sulfamethoxazole or azithromycin use, and diabetes mellitus were not associated with recurrence.

Randomized controlled trial of cephalexin versus clindamycin for uncomplicated pediatric skin infections

Chen AE, Carroll KC, Diener-West M, Ross T, Ordun J, Goldstein MA, et al. *Pediatrics* 2011; 127: e573–80.

This was a comparison of clindamycin and cephalexin for the treatment of uncomplicated SSTIs caused predominantly by CA-MRSA. Of the 200 enrolled patients, 69% demonstrated MRSA on wound cultures. Spontaneous drainage or a drainage procedure occurred in 97% of subjects. There is no significant difference between cephalexin and clindamycin in this study.

The data presented here is similar to previous data. The treatment for an uncomplicated abscess remains drainage, and the use of an antibiotic has little effect on outcome.

Comparative effectiveness of antibiotic treatment strategies for pediatric skin and soft-tissue infections

Williams DJ, Cooper WO, Kaltenbach LA, Dudley JA, Kirschke DL, Jones TF, et al. *Pediatrics* 2011; 128: e479–87.

In a study of 6407 children who underwent drainage for MRSA infections, there were 568 treatment failures (8.9%). The rate of recurrence was high (22.8%). The adjusted odds ratios for treatment failure were 1.92 (95% CI, 1.49–2.47) for trimethoprim–sulfamethoxazole and 2.23 (95% CI, 1.71–2.90) for β -lactams. Among the 41,094 children without a drainage procedure, there were 2435 treatment failures (5.9%), but the rate of recurrence was similar to the rate in those who required drainage (18.2%). The adjusted odds ratios for treatment failure were 1.67 (95% CI, 1.44–1.95) for trimethoprim–sulfamethoxazole and 1.22 (95% CI, 1.06–1.41) for β -lactams. The authors concluded that, compared with data for clindamycin, use of either trimethoprim–sulfamethoxazole or β -lactams was associated with an increased risk of treatment failure.

MRSA abscesses typically respond to drainage alone, and it is the adequacy of the drainage procedure rather than the choice of antibiotic that is the prime determinant of outcome. It would also be important to know the local prevalence of inducible clindamycin resistance before recommending clindamycin over trimethoprim–

sulfamethoxazole when an antibiotic is needed.

Prevention of recurrent staphylococcal skin infections

Creech CB, Al-Zubeidi DN, Fritz SA. Infect Dis Clin North Am 2015; 29: 429–64.

Staphylococcal infections often cluster within households, and asymptomatic carriers serve as reservoirs for transmission. A household approach to decolonization and fomite control is more effective than measures performed by individuals alone.

***Staphylococcus aureus* colonization and strain type at various body sites among patients with a closed abscess and uninfected controls at U.S. emergency departments**

Albrecht VS, Limbago BM, Moran GJ, Krishnadasan A, Gorwitz RJ, McDougal LK, et al. J Clin Microbiol 2015; 53: 3478–84.

Staphylococcal-infected subjects were usually colonized with the infecting strain. Among MRSA-infected subjects, the most common site was the groin.

Moist areas of skin are commonly colonized with MRSA. Interventions that only address nasal carriage are inferior to those that also address skin carriage, especially in the groin, axillae, and umbilicus.

The impact of hospital-acquired methicillin-resistant *Staphylococcus aureus* in a burn population after implementation of universal decolonization protocol

Johnson AT, Nygaard RM, Cohen EM, Fey RM, Wagner AL. J Burn Care Res 2016; 37: e525–30.

Universal decolonization of all patients with daily chlorhexidine baths and a 5-day course of nasal mupirocin was effective in reducing mortality in an adult and pediatric burn unit.

Effectiveness of simple control measures on methicillin-resistant *Staphylococcus aureus* infection status and characteristics with susceptibility patterns in a teaching hospital in Peshawar

Rafiq MS, Rafiq MI, Khan T, Rafiq M, Khan MM. J Pak Med Assoc 2015; 65: 915–20.

Barrier precautions remain a key intervention to prevent the spread of MRSA infection.

Prospective investigation of nasal mupirocin, hexachlorophene body wash, and systemic antibiotics for prevention of recurrent community-associated methicillin-resistant *Staphylococcus aureus* infections

Miller LG, Tan J, Eells SJ, Benitez E, Radner AB. Antimicrob Agents Chemother 2012; 56: 1084–6.

In a prospective study of 31 patients with recurrent CA-MRSA skin infections who received nasal mupirocin, topical hexachlorophene body wash, and an oral anti-MRSA antibiotic, the mean number of infections after the intervention decreased significantly (0.03 vs. 0.84 infections/month, $p \leq 0.0001$).

Among patients with recurrent infection, some data suggest that decolonization can reduce the rate of future recurrences.

Targeted intranasal mupirocin to prevent colonization and infection by community-associated methicillin-resistant *Staphylococcus aureus* strains in soldiers: a cluster randomized controlled trial

Ellis MW, Griffith ME, Dooley DP, McLean JC, Jorgensen JH, Patterson JE, et al. Antimicrob Agents Chemother 2007; 51: 3591–8.

Second-Line Therapy

• Vancomycin ± rifampin	B
• Linezolid and newer oxazolidinones	A
• Dalbavancin	B
• Telavancin	B
• Daptomycin	B

Eradication of colonization: nares

• Retapamulin	D
• Triple antibiotic ointment	D
• Silver sulfadiazine cream	D

Eradication of colonization: skin

• Benzoyl peroxide soap	E
• Zinc pyrithione soap	E

Weight-based antibiotic dosing in a real-world European study of complicated skin and soft-tissue infections due to methicillin-resistant *Staphylococcus aureus*

Lawson W, Nathwani D, Eckmann C, Corman S, Stephens J, Solem C, et al. Microbiol Infect 2015; 21 (Suppl 2): S40–6.

Real-world dosing of weight-based intravenous (IV) antibiotic therapy in patients hospitalized for complicated MRSA SSTIs were assessed by means of data from 12 European countries. Patients had been treated with IV vancomycin, teicoplanin, or daptomycin. Low, standard (labeled), and high dosing groups were assessed in 1502 patients. The majority of patients receiving first-line teicoplanin and daptomycin (96% and 80%, respectively) received higher than labeled complicated SSTI doses. In contrast, vancomycin doses were lower than labeled doses in >40% of patients.

This real-world data reveals significant deviations from labeled antibiotic dosing and suggests that fear of vancomycin toxicity may affect management.

Randomized controlled noninferiority trial comparing daptomycin to vancomycin for the treatment of complicated skin and skin structure infections in an observation unit

Shaw GJ, Meunier JM, Korfhagen J, Wayne B, Hart K, Lindsell CJ, et al. J Emerg Med 2015; 49: 928–36.

In a study of 100 patients, daptomycin was not inferior to vancomycin in the treatment of complicated SSTIs.

An open-label, pragmatic, randomized controlled clinical trial to evaluate the comparative effectiveness of daptomycin versus vancomycin for the treatment of complicated skin and skin structure infection

Kauf TL, McKinnon P, Corey GR, Bedolla J, Riska PF, Sims M, et al. BMC Infect Dis 2015; 15:503.

The primary end point of this study was infection-related length of stay. Secondary end points included health care resource utilization, cost, clinical response, and patient-reported outcomes. There were no significant differences between the two, although vancomycin was associated with a lower likelihood of day 2 clinical success (odds ratio [OR]=0.498, 95 % CI, 0.249–0.997; $P<0.05$).

Other factors, including cost, may be more important than efficacy in driving the decision of which therapy to use.

Dalbavancin: a novel lipoglycopeptide antibiotic with extended activity against gram-positive infections

Smith JR, Roberts KD, Rybak MJ. Infect Dis Ther 2015; 4: 245–58.

Lipoglycopeptides have extended half-lives and are effective against MRSA.

In vitro activity of ceftaroline against bacterial pathogens isolated from skin and soft tissue infections in Europe, Russia and Turkey in 2012: results from the Assessing Worldwide Antimicrobial Resistance Evaluation (AWARE) surveillance programme

Karlowisky JA, Biedenbach DJ, Bouchillon SK, Iaconis JP, Reiszner E, Sahm DF. J Antimicrob Chemother 2016; 71: 162–9.

Most ceftaroline-nonsusceptible isolates were from Russia, Turkey, Italy, and Hungary. Ceftaroline susceptibility was 99% for *S. aureus* isolates submitted by 7 of 17 countries.

In most areas, ceftaroline continues to demonstrate potent in vitro activity against contemporary strains of bacteria, including MRSA.

In vitro activities of tedizolid and linezolid against gram-positive

cocci associated with acute bacterial skin and skin structure infections and pneumonia

Chen KH, Huang YT, Liao CH, Sheng WH, Hsueh PR. Antimicrob Agents Chemother 2015; 59: 6262–5.

Tedizolid is a novel, expanded-spectrum oxazolidinone with potent activity against a wide range of gram-positive pathogens. This study of 425 isolates of gram-positive bacteria from patients with acute bacterial skin and skin structure infections or pneumonia included 100 MRSA isolates. Tedizolid exhibited better in vitro activities than linezolid against MRSA (MIC₉₀s, 0.5 vs. 2 µg/mL) as well as MSSA (MIC₉₀s, 0.5 vs. 2 µg/mL), *S. pyogenes* (MIC₉₀s, 0.5 vs. 2 µg/mL), *S. agalactiae* (MIC₉₀s, 0.5 vs. 2 µg/mL), *Streptococcus anginosus* group (MIC₉₀s, 0.5 vs. 2 µg/mL), *Enterococcus faecalis* (MIC₉₀s, 0.5 vs. 2 µg/mL), and vancomycin-resistant enterococci (VRE) (MIC₉₀s, 0.5 vs. 2 µg/mL).

Tedizolid exhibited two- to fourfold better in vitro activities against a variety of gram-positive cocci compared with linezolid.

Third-Line Therapies

• Tigecycline	B
• Ceftobiprole, ceftaroline	C
• Oritavancin	C
• Honey and bee venom	D
• Topical simvastatin	E
• Topical celecoxib	E
• Nanoparticles	E
• Confectioner's sugar	E
• Sugar and povidone iodine	E
• Botanical extracts	D

Dalbavancin and oritavancin: an innovative approach to the treatment of gram-positive infections

Roberts KD, Sulaiman RM, Rybak MJ. Pharmacotherapy 2015; 35: 935–48.

In 2014, the U.S. Food and Drug Administration approved two new lipoglycopeptides, oritavancin and dalbavancin, for the treatment of acute bacterial skin and skin structure infections. They demonstrate increased potency against MRSA compared with vancomycin.

Currently, there is more data concerning dalbavancin than oritavancin, but both are promising additions to our armamentarium.

Exploration of alginate hydrogel/nano zinc oxide composite

bandages for infected wounds

Mohandas A, Kumar PTS, Raja B, Lakshmanan VK, Jayakumar R. Int J Nanomedicine 2015; 10 (Suppl 1): 53–66.

The prepared composite bandages exhibited excellent antimicrobial activity against MRSA.

These bandages have a nontoxic nature at lower concentrations of nano zinc oxide.

Melittin, a honeybee venom-derived antimicrobial peptide, may target methicillin-resistant *Staphylococcus aureus*

Choi JH, Jang AY, Lin S, Lim S, Kim D, Park K, et al. Mol Med Rep 2015; 12: 6483–90.

Both honey and melittin demonstrate activity against MRSA.

Exploring simvastatin, an antihyperlipidemic drug, as a potential topical antibacterial agent

Thangamani S, Mohammad H, Abushahba MF, Hamed MI, Sobreira TJ, Hedrick VE, et al. Sci Rep 2015; 5: 16407.

Simvastatin, used systemically as a lipid-lowering agent, demonstrated broad-spectrum antibacterial activity against gram-positive organisms, including MRSA, when used topically. It also demonstrated the ability to suppress production of the key MRSA toxins α -hemolysin and Panton–Valentine leukocidin.

The most intriguing finding of this study was that simvastatin exhibits excellent antibiofilm activity against established staphylococcal biofilms.

Repurposing celecoxib as a topical antimicrobial agent

Thangamani S, Younis W, Seleem MN. Front Microbiol 2015 28; 6: 750.

Celecoxib, a marketed inhibitor of cyclooxygenase-2, exhibits broad-spectrum antimicrobial activity against gram-positive pathogens, including MRSA. The primary antimicrobial mechanism of action is dose-dependent inhibition of ribonucleic acid (RNA), deoxyribonucleic acid (DNA), and protein synthesis.

Topical application of celecoxib significantly reduced the mean bacterial count in a mouse model of MRSA skin infection.

Nordihydroguaiaretic acid enhances the activities of aminoglycosides against methicillin-sensitive and resistant

***Staphylococcus aureus* in vitro and in vivo**

Cunningham-Oakes E, Soren O, Moussa C, Rathor G, Liu Y, Coates A, et al. Front Microbiol 2015; 6: 1195.

Nordihydroguaiaretic acid (NDGA) is an antioxidant compound extracted from the plant *Larrea tridentata*. Antimicrobial activity targets the bacterial cell membrane.

In this study of 200 clinical isolates of MRSA and MSSA, NDGA demonstrated synergy with aminoglycosides in a murine skin infection model.

Effect of medical honey on wounds colonised or infected with MRSA

Blaser G, Santos K, Bode U, Vetter H, Simon A. J Wound Care 2007; 16: 325–8.

In seven patients with nonhealing wounds infected or colonized with MRSA who had failed other antiseptics and antibiotics, honey resulted in complete healing.

My grandmother, Anny Elston, MD, reported that as a World War I medic she used confectioner's sugar to treat infected ulcers in returning prisoners of war. All ulcers healed. The treatment is inexpensive, and resistance to the desiccating effects of sugar is unlikely.

PVL-SA Management Strategy

Microbiologic swabs should be taken and PVL polymerase chain reaction (PCR) testing requested, as this may not be routinely undertaken. Small abscesses require drainage only. Lesions should be covered, and towels and other possible fomites should not be shared. Lesions over 5 cm in diameter or when there is also cellulitis require antibiotics (flucloxacillin or clindamycin), usually orally for 5 to 7 days. Where MRSA PVL infection is suspected, rifampicin plus either doxycycline, fusidic acid or trimethoprim, or clindamycin as monotherapy. For severe and invasive infections, such as pyomyositis or toxic shock, parenteral vancomycin, teicoplanin, daptomycin, or linezolid have been used in combination with high-dose intravenous immunoglobulin (IVIG) (2 day) in addition to drainage and debridement.

Decolonization is recommended to prevent transmission to close

contacts with 4% chlorhexidine soap or 2% triclosan for 5 days and mupirocin nasal cream daily for 5 days to the nares.

Specific Investigations

- Swabs for culture and PVL PCR
- If PVL infection is suspected, it is important to specifically request PVL PCR, as it is not routinely performed

First-Line Therapy

• Drainage of small abscesses	C
• Drainage and antibiotics for larger abscesses (over 5 cm) and if cellulitis evident	
• Flucloxacillin 500 mg four times a day for 5 days	C
• Clindamycin 450 mg four times a day for 5 days	C
• Decolonization	C

If PVL MRSA is suspected or confirmed

• Rifampicin 300 mg twice daily plus doxycycline 100 mg twice daily	C
• Rifampicin 300 mg twice daily plus fusidic acid 500 mg three times a day	C
• Rifampicin 300 mg twice a day plus trimethoprim 200 mg twice a day	C
• Clindamycin 450 mg four times a day	C

Guidance on the diagnosis and management of PVL-associated *Staphylococcus aureus* Health Protection Agency UK 2008

Available online at www.hpa.org.uk.

This document gives detailed advice regarding PVL infection, including patient information leaflets and practical advice about decolonization.

Decolonization is performed with either chlorhexidine body wash or shampoo or 2% triclosan. The product is applied to wetted skin directly without dilution daily for 5 days –it should be washed off after 1 minute. Individual towels are needed and, if possible, changed daily. Mupirocin nasal cream (about a matchstick head-sized

amount) should be applied to the inner surface of each nostril on a cotton bud and massaged inside the nostrils thrice daily for 5 days.

Second- Line Therapies

• Vancomycin	D
• Teicoplanin	D
• Daptomycin	D
• Linezolid	D
• IVIG	D

Guidance on the diagnosis and management of PVL-associated *Staphylococcus aureus*. Health Protection Agency UK 2008

Serious life-threatening infection will need advice from microbiologists and infectious disease specialists.

Miliaria

Kelly R. Kane, Sandra Pena, and Warren R. Heymann

Miliaria is a benign, transient disorder caused by occlusion and resultant injury in the eccrine duct. It is subdivided into miliaria crystallina, miliaria rubra, and miliaria profunda, based on the level of obliteration. Miliaria crystallina, the most superficial form (sudamina), occurs with occlusion of the sweat duct in the stratum corneum. It is self-limiting and typically appears as clear vesicles without significant erythema. Miliaria rubra (“prickly heat”) is the most common, presenting as numerous pruritic nonfollicular papules or vesicles with surrounding erythema. The obstruction occurs within the eccrine duct in the stratum malpighii. Typically it occurs on the trunk, neck, or back but can affect other areas and has been reported to occur under splints or braces and military uniforms because of the

warm occlusive environment. Miliaria profunda is uncommon, classically occurring at the dermoepidermal junction or dermis; however, advances in imaging have begun to cause physicians to question this understanding. Miliaria profunda is typically seen after repeated cases of miliaria rubra in tropical settings. These patients can also have associated systemic symptoms related to overheating.

Management Strategy

Miliaria most typically occurs as a result of excessive sweating in hot, humid conditions, prolonged perspiration, or after extended febrile illness. There are other less common reports of congenital miliaria, miliaria occurring after medication administration in the intensive care setting, and in association with congenital illnesses such as pseudohypoaldosteronism (PHA) and with hypernatremia. Miliaria is often exacerbated by tight clothing and high humidity. Management begins with *removal of the inciting factors*. There is no strong evidence for the various treatment options.

Adults often develop miliaria during travel in the tropics, military service, or with heavy exercise. *Gradual exposure* helps to acclimatize to a hot and humid environment, but this may take a few months. *Loose-fitting clothing, fans, and cool showers* may minimize the symptoms. With the use of any topical lotion or cream, care must be taken to ensure that the product applied does not occlude the skin, further exacerbating the condition. In the case of severe itching, *antihistamines, cold packs, and topical corticosteroids* may be used. *Oatmeal baths* have been anecdotally reported to provide relief. However, all these measures will prove ineffective if the sweating is not reduced. All cases will respond to *air conditioning, exposure of the involved skin*, and the use of *antipyretics* in appropriate circumstances. Miliaria profunda has been reported to respond to oral retinoids and anhydrous lanolin.

Miliaria may be complicated by superinfection; it should be treated with *systemic antibiotics* aimed at Staphylococci as the likely pathogen. Clinicians should make patients aware that anhidrosis in the area of the eruption may occur and persist up to 3 weeks (or sometimes even longer) after the onset of lesions, and increased heat retention may occur if a large surface area was initially affected. Thus patients at risk of heat exhaustion or heat stroke should take precautions to remain in air-conditioned environments during hot weather. A biopsy may be

helpful in atypical cases of miliaria.

Specific Investigations

- None usually required

In atypical cases

- Microbiology—swab for bacteria and yeasts
- Histology
- Advanced imaging—high-definition optical coherence tomography (HD-OCT)

Nonneoplastic disorders of the eccrine glands

Wenzel FG, Horn TD. J Am Acad Dermatol 1998; 38: 1–7.

The histology and pathophysiology of eccrine sweat ducts are reviewed. The erythematous macule or papule of miliaria rubra occurs with an obstruction of the sweat duct at the stratum malpighii. In the case of miliaria crystallina, the disruption is in the stratum corneum and, with miliaria profunda, at or beneath the dermoepidermal junction. The pathogenesis of miliaria is reviewed, describing the role of resident bacteria and periodic acid–Schiff (PAS)-positive extracellular polysaccharide substance blocking eccrine ducts.

Duct disruption, a new explanation of miliaria

Shuster S. Acta Derm Venereol 1997; 77: 1–3.

A hypothesis is presented that ascribes miliaria crystallina to mechanical disruption of the eccrine duct, rather than the commonly accepted pathogenesis of duct plugging. This disruption is attributed to ultraviolet irradiation causing a split between upper epidermal cells and the stratum corneum.

The role of extracellular polysaccharide substance produced by *Staphylococcus epidermidis* in miliaria

Mowad CM, McGinley KJ, Foglia A, Leyden JJ. J Am Acad Dermatol 1995; 33: 729–33.

The ability of various strains of coagulase-negative staphylococci to induce miliaria under an occlusive dressing was evaluated. *Staphylococcus epidermidis* was the only strain that induced miliaria.

The authors conclude that PAS-positive extracellular polysaccharide substance produced by *S. epidermidis* plays a central role in the pathogenesis of miliaria by obstructing sweat delivery.

A novel finding in atopic dermatitis: film-producing *Staphylococcus epidermidis* as an etiology

Allen HB, Meuller JL. Int J Dermatol 2011; 50: 992–3.

S. epidermidis biofilm was cultured in a patient with atopic dermatitis. The authors proposed subclinical miliaria contributes to pruritus in atopic patients.

The pathogenesis of miliaria rubra: role of the resident microflora

Holzle E, Kligman AM. Br J Dermatol 1978; 99: 117–37.

The degree of miliaria rubra and anhidrosis induced in 55 subjects was directly correlated with the density of resident flora present on occluded areas of skin, as measured by detergent scrub and culture. A historical overview of research into the pathogenesis of miliaria rubra is included.

Miliaria crystallina in an intensive care setting

Haas N, Martens F, Henz BM. Clin Exp Dermatol 2004; 29: 32–4.

Two cases of miliaria crystallina occurring in an intensive care setting are presented. The authors hypothesize that the mechanism is secondary to transient poral closure due to the drugs used in the intensive care setting that may have stimulated sweating.

Pruritus, papules and perspiration

LaShell M, Tankersley M, Guerra A. Ann Allergy Asthma Immunol 2007; 98: 299–302.

This article reviews common exercise-induced eruptions, with miliaria rubra being discussed as the cause of the patient's recurring, self-limited eruption occurring with indoor exercise or hot tub exposure. Exercise challenge re-created the clinical picture and confirmed the diagnosis.

Miliaria-rash after neutropenic fever and induction chemotherapy for acute myelogenous leukemia

Nguyen TA, Stevens MP. An Bras Dermatol 2011; 86: 104–6.

A 40-year-old female developed miliaria crystallina after

developing neutropenic fevers while on treatment with idarubicin and cytarabine. Treatment of the underlying fever led to resolution of cutaneous lesions. A review of miliaria and excessive perspiration associated with medications, including doxorubicin, bethanechol, salbutamol, and clonidine, is discussed.

Newborn with pseudohypoaldosteronism and miliaria rubra

Akcakus M, Koklu E, Poyrazoglu H, Kurtoglu S. *Int J Dermatol* 2006; 45: 1432–4.

Autosomal-recessive type I PHA as a cause of miliaria is discussed in a patient who developed miliaria rubra specifically during salt depletion crises. The rash cleared after stabilization of electrolytes and reappeared upon hyponatremia. The miliaria rubra seen in this patient was felt to be due to high concentrations of sodium chloride in the sweat directly damaging eccrine ducts.

Miliaria rubra and thrombocytosis in pseudohypoaldosteronism: case report

Onal H, Erdal A, Ersenb A, Onal Z, Keskindemircia G. *Platelets* 2012; 23: 645–7.

The authors report a case of miliaria rubra and thrombocytosis in a 6-month-old girl with PHA. They hypothesize that sympathetic activation provides vascular tonus during sodium excretion in sweat, and salt depletion crisis may play a role in the development of skin lesions and thrombocytosis in patients with PHA.

Widespread miliaria crystallina in a newborn with hypernatremic dehydration

Engür D, Türkmen MK, Savk E. *Pediatr Dermatol* 2013; 30: e234–5.

The authors present a case of extensive, widespread miliaria crystallina that developed in a newborn with severe hypernatremic dehydration. They propose the destruction of sweat ducts with excretion of sweat with high levels of sodium as a possible mechanism.

In vivo imaging of miliaria profunda using high-definition optical coherence tomography: diagnosis, pathogenesis, and treatment

Tey HL, Tay EY, Cao T. *JAMA Dermatol* 2015; 151: 346–8.

Two cases of miliaria profunda were evaluated using HD-OCT. In the epidermis, the authors identified dilated spiraling acrosyringium

and an adjacent hyperrefractile substance, which they believed to be keratin. As a result of their finding, the authors challenge our prior understanding of the location of the obstruction.

First-Line Therapies

• Prevention	D
• Frequent showering	E
• Air conditioning	B
• Oatmeal baths	E
• Topical antiseptics	E
• Antipyretics	E

Miliaria rubra of the lower limbs in underground miners

Donoghue AM, Sinclair MJ. Occup Med (Lond) 2000; 50: 430–3.

Case series of 25 miners working in a hot and humid environment who developed miliaria. Symptoms resolved after 4 weeks of sedentary duties in the air-conditioned areas. This report also analyzed coexisting dermatologic conditions in these patients.

Diseases of the eccrine and apocrine sweat glands

Miller JL. In: Bologna JL, Jorizzo JL, Rapini RP, eds. Dermatology. Philadelphia: Mosby, 2012; 34–11.

Preventative measures, such as a cool environment, for days to weeks is the primary goal to prevent excessive sweating and

maceration of the stratum corneum.

Goosefleshlike lesions and hypohidrosis

Dimon NS, Fullen DR, Helfrich YR. Arch Dermatol 2007; 43: 1323–8.

Numerous treatments for miliaria are described, including anhydrous lanolin, oral isotretinoin, regular bathing to remove salt and bacteria, and antibiotics.

Congenital miliaria crystallina in a term neonate born to a mother with chorioamnionitis

Babu TA, Sharmila V. Pediatr Dermatol 2012; 29: 306–7.

A case report of a full-term infant, whose birth was complicated by chorioamnionitis, presented at delivery with miliaria crystallina that self-resolved in 3 days. The authors proposed that prolonged rupture of membranes, maternal fever, and warm amniotic fluid may have contributed to fetal sweating and development of miliaria. Conservative and preventative measures are emphasized.

Second-Line Therapies

• Topical corticosteroids	E
• Systemic antibiotics	E

Miliaria rubra

Siddiqi A. In: Domino FJ, ed. 5-Minute Clinical Consult (online). Philadelphia: Lippincott Williams & Wilkins, 2012; 1–4.

For relief of pruritus, 0.1% betamethasone twice daily for 3 days may be applied over the affected area. In the event of superimposed infection, an antistaphylococcal agent such as dicloxacillin (flucloxacillin) 250 mg four times daily for 10 days may be used.

Heat illness: prickly heat

Platt M, Vicario S. In: Marx JA, ed. Rosen's Emergency Medicine: Concepts and Clinical Practice, 7th edn. Vol 2. Philadelphia: Mosby,

2009; 1887.

If a case of miliaria rubra becomes diffuse or pustular, oral erythromycin has been shown to be helpful. During the most acute phase of miliaria rubra, chlorhexidine lotion or cream can be used as an antibacterial agent, with salicylic acid 1% three times daily over small areas to aid in desquamation (not to be used in children).

Third-Line Therapies

• Anhydrous lanolin/isotretinoin	E
• Ascorbic acid	B
• Intramuscular steroids	E

Miliaria profunda

Kirk JF, Wilson BB, Chun W, Cooper PH. J Am Acad Dermatol 1996; 35: 854–6.

This case report describes a 23-year-old man with miliaria profunda successfully treated with both anhydrous lanolin and isotretinoin after a poor response to topical corticosteroids. The impact of either as an individual treatment is therefore difficult to assess.

The effects of administration of ascorbic acid in experimentally induced miliaria and hypohidrosis in volunteers

Hindson TC, Worsley DE. Br J Dermatol 1969; 81: 226–7.

Miliaria and hypohidrosis were induced in 36 subjects, half of whom were given 1 g daily of ascorbic acid and half a placebo, beginning on the day of wrapping the skin with polythene occlusion. Compared with the placebo group, the ascorbic acid group developed less severe miliaria and hypohidrosis, had quicker healing of visible lesions, and had notable improvement in hypohidrosis at 1 week.

Patients presenting with miliaria while wearing flame resistant clothing in high ambient temperatures: a case series

Carter R, Garcia AM, Souhan BE. J Med Case Reports 2011; 5: 474.

Two cases of miliaria rubra are reported in military personnel wearing flame-resistant army combat uniforms (FRACU) in arid environments. Both patients received 250 mg intramuscular methylprednisolone, and one was continued on triamcinolone acetonide 0.1% cream twice daily for 1 week. Resolution was achieved; however, relapse with repeated FRACU use occurred.

Molluscum contagiosum

Ian H. Coulson, and Tashmeeta Ahad

Molluscum contagiosum (MC) is a common, self-limiting poxvirus infection of the skin and occasionally mucous membranes. Lesions occur in children, usually on the trunk and body folds, and in young adults, if sexually transmitted, in the genital region. They typically present as multiple 1- to 10-mm-diameter, discrete, pearly white or flesh-colored, umbilicated papules. They may be surrounded by an eczematous reaction, which can be managed with topical steroids if

symptomatic. Mollusca may be very extensive and recalcitrant to treatment in all forms of cell-mediated immunosuppression, especially in patients with AIDS.

Management Strategy

There is no specific antiviral therapy for MC. Physical and chemical destructive methods of treatment, as well as topical and systemic immunostimulatory therapies, have been tried, but no single intervention has been convincingly shown to be effective. Only a few have been subjected to the rigors of placebo-controlled studies, important for a condition that has a high spontaneous resolution rate. A Cochrane systematic review performed in 2009 reviewing randomized trials investigating the efficacy of treatments for MC found insufficient evidence to conclude that any treatment was definitively effective.

The choice of therapy will depend on the age and immune status of the patient, as well as the number and location of the lesions. In immunocompetent patients with few lesions, it is reasonable to *await spontaneous resolution*, which will usually occur within a few months. Secondarily infected MC may need *topical antiseptic or antibiotic* treatment to minimize the risk of atrophic scarring. Active intervention may be justified for cosmetic reasons, in immunodeficient states, or to hasten resolution, in order to prevent autoinoculation or transmission of the virus to close contacts. Avoidance of communal bathing and restriction of the sharing of towels should also help prevent the spread of infection to others.

A commonly used and inexpensive treatment is the *manual extrusion* of individual lesions using gloved fingers or fine forceps. This has proved more effective than *cryotherapy single treatment for 5 to 10 seconds, applied every 2 to 3 weeks*. *Curettage and electrodesiccation* of larger lesions may result in scarring and also requires pain alleviation, especially in children, by the prior application of a eutectic mixture of local anesthetics (lidocaine and prilocaine cream). Topically applied caustic agents have been used with variable results. Good success rates are reported with topical application of *0.5% podophyllotoxin applied twice daily for three consecutive days per week up to 4 weeks*. Other topical applications include *40% silver nitrate paste one to three applications (after 2% lidocaine gel)*, *10% povidone–iodine with 50% salicylic acid applied daily*, *5% acidified nitrite, applied nightly with 5%*

salicylic acid under occlusion, and topical salicylic acid 12% gel.

Significant scarring has been documented with both *potassium hydroxide* (5% or 10% KOH frequency ranging from three times a week to twice daily) and *phenol*, and the latter is no longer recommended.

Cantharidin, a clinician-applied topical blistering agent washed off 2 to 6 hours later, has proved to be an effective treatment but is not readily available. There has been some controversy about the use of *imiquimod* 5% cream for MC, as two unpublished large randomized control trials have shown lack of efficacy. In patients with AIDS, both 1% *imiquimod* and *topical cidofovir* 3%, a competitive inhibitor of DNA polymerase, have proved successful for treating MC. Recovery of immune function with *highly active antiretroviral therapy* (HAART) may also result in the resolution of MC in these patients.

Specific Investigation

- Methylene blue staining of a smear to look for molluscum bodies or histopathology of a curetted specimen
This is only required when the diagnosis is in doubt.

First-Line Therapies

• Await spontaneous resolution	B
• Manual extrusion with gloved fingers or fine forceps	B

Time to resolution and effect on quality of life of molluscum in children in the UK: a prospective community cohort study

Olsen JR, Gallacher J, Finlay AY, Piguet V, Francis NA. *Lancet Infect Dis* 2015; 15: 190–5.

In 306 children, aged between 4 and 15, mean time to resolution of molluscum was 13.3 months. Eighty (30%) of 269 cases had not resolved by 18 months, and 36 (13%) had not resolved by 24 months. MC had a small effect on quality of life for most participants, although 33 (11%) of 301 participants had a very severe effect on quality of life (Children's Dermatology Life Quality Index score >13).

Scarring in molluscum contagiosum: comparison of physical expression and phenol ablation

Weller R, O'Callaghan CJ, MacSween RM, White MI. Br Med J 1999; 319: 1540.

There was no difference in overall efficacy of the two methods, but phenol resulted in significantly more scarring.

For manual extrusion, wear gloves and squeeze or use fine forceps and discard extruded curdlike material. Lesions may take 1 to 2 weeks to improve.

Second-Line Therapies

• Cryotherapy	C
• Topical 0.5% podophyllotoxin	A
• Topical 5% acidified nitrite coapplied with 5% salicylic acid	A
• Topical salicylic acid gel 12%	A
• Topical 10% povidone–iodine and 50% salicylic acid	B
• Topical 40% silver nitrate paste	B

Molluscum contagiosum in children: evidence-based treatment

White MI, Weller R, Diack P. Clin Exp Dermatol 1997; 22: 51.

This study compared the efficacy and the potential for scarring of manual extrusion, cryotherapy, and topical phenol. Manual extrusion was more effective than cryotherapy. Phenol was associated with significant scarring and is not recommended for the treatment of MC.

Despite the lack of large placebo-controlled trials exploring cryotherapy, treatment is usually rapid, and therefore its use is supported. Cryotherapy should be applied once, for 5 to 10 seconds, directly on the lesion. This can be repeated every 2 to 3 weeks until the lesion has gone. A topical anesthetic (such as lidocaine/prilocaine cream) 1 hour before treatment, can be used, especially if a cluster of lesions is being treated. Potential adverse effects include scarring or hypopigmentation.

Topical 0.3% and 0.5% podophyllotoxin cream for self-treatment of molluscum contagiosum in males. A placebo-controlled,

double-blind study

Syed TA, Lundin S, Ahmad M. *Dermatology* 1994; 189: 65–8.

In this randomized trial of 150 males aged 10 to 26 with lesions mostly located on the thighs or genitalia, 0.5% podophyllotoxin cream, 0.3% podophyllotoxin cream, or placebo cream was applied twice daily for three consecutive days per week for a duration of up to 4 weeks. Cure rates were 92%, 52%, and 16%, respectively.

Podophyllotoxin is an antimitotic agent, the safety and efficacy of which have not yet been definitively established in young children. Potential adverse effects include pruritus, burning, and inflammation.

Molluscum contagiosum effectively treated with a topical acidified nitrite, nitric oxide liberating cream

Ormerod AD, White MI, Shah SAA, Benjamin N. *Br J Dermatol* 1999; 141: 1051–3.

A double-blind study in 30 children of sodium nitrite 5% coapplied nightly with 5% salicylic acid under occlusion resulted in a cure rate of 75%, compared with 21% with salicylic acid alone. Mean duration to cure was 1.83 months. Adverse effects included staining of the skin and irritation.

Topical therapy with salicylic gel as a treatment for molluscum contagiosum in children

Leslie KS, Dootson G, Sterling JC. *J Dermatol Treat* 2005; 16: 336–40.

One hundred fourteen children with MC were treated with monthly 70% alcohol vehicle, monthly phenol 10%, or salicylic acid gel 12% applied once or twice weekly. Salicylic acid was well tolerated and significantly better (87%) than the vehicle alone (59%) or phenol (56%) at clearing MC. There was no difference in efficacy when analyzed on an “intention to treat” basis.

Molluscum contagiosum treated with iodine solution and salicylic acid plaster

Ohkuma M. *Int J Dermatol* 1990; 29: 443–5.

Povidone–iodine solution 10% and 50% salicylic acid plaster applied daily to MC in 20 patients was significantly more effective than either agent used alone, with a mean duration to clearance of 26 days and with no adverse effects.

Treatment of molluscum contagiosum with silver nitrate paste

Niizeki K, Hashimoto K. *Pediatr Dermatol* 1999; 16: 395–7.

In 389 patients, topical 40% silver nitrate paste was applied after 2% lidocaine gel; 70% cleared after one application, 97.7% after three applications. Treatment was well tolerated, and no scarring was reported. It was easier to apply than a 40% aqueous solution of silver nitrate.

Third-Line Therapies

Physical destruction

• Curettage with topical local anaesthesia cream	C
• Pulsed dye laser	C
• Photodynamic therapy	D

Topical therapy

• Application of duct tape	E
• Cantharidin	B
• 10% potassium hydroxide solution	A
• Topical 1%–5% imiquimod	A
• Diphencyprone	C
• Australian lemon myrtle	C
• Topical cidofovir	E
• Tretinoin	E
• Adapalene	E
• <i>Melaleuca alternifolia</i> and iodine	C
• Ingenol mebutate 0.015%	E
• Sinecatechins 10% ointment	E

Systemic therapy

• <i>Candida</i> antigen – intralesional	C
• Cimetidine	D
• Interferon- α – subcutaneous	E

Treatment of molluscum contagiosum using a lidocaine/prilocaine cream (EMLA) for analgesia

de Waard-van der Speck FB, Oranje AP, Lillieborg S, Hop WC, Stolz E. *J Am Acad Dermatol* 1990; 23: 685–8.

A double-blind study in 83 children showed efficacy of EMLA cream applied for less than 60 minutes in reducing the pain of curettage, though no comment was made on clearance rates.

Curettage treatment for molluscum contagiosum: a follow-up survey study

Simonart T, De Maertelaer V. *Br J Dermatol* 2008; 159: 1144.

In this 2-month prospective study of 73 patients treated with curettage, 66% of patients were not cured after a single session, and 45% of patients failed to clear after two sessions. Risk factors for treatment failure included higher number of lesions and atopic dermatitis.

A prospective randomized trial comparing the efficacy and adverse effects of four recognized treatments of molluscum contagiosum in children

Hanna D, Hatami A, Powell J, Marcoux D, Maari C, Savard P, et al. *Pediatr Dermatol* 2006; 23: 574–9.

A prospective randomized study comparing four common treatments for MC in 124 children (curettage with topical anesthesia, cantharidin 0.7% (applied for 2–4 hours), salicylic acid 16.7% plus lactic acid 16.7% (Duofilm) three times per week, and imiquimod 5% three times per week). Curettage was the most effective, with 80% cure rate and the fewest side effects. Cantharidin and salicylic acid produced irritation. Imiquimod was promising, but the optimum dosing regimen is still to be determined.

Treatment of molluscum contagiosum with the pulsed dye laser over a 28-month period

Hancox JG, Jackson J, McCagh S. *Cutis* 2003; 71: 414–6.

All treated lesions in 43 patients resolved, and in 15 of them no further lesions developed after two treatments.

Photodynamic therapy for molluscum contagiosum infection in HIV-coinfected patients: review of 6 cases

Moiin A. *J Drugs Dermatol* 2003; 6: 637–9.

Treatment of six patients with 5-aminolevulinic acid (ALA) and photodynamic therapy (PDT) resulted in a reduction in lesion count

and severity.

Use of duct tape occlusion in the treatment of recurrent molluscum contagiosum

Lindau MS, Munar MY. *Pediatr Dermatol* 2004; 21: 609.

Case report of well-tolerated and successful home therapy of multiple MC used over 2 months.

Childhood molluscum contagiosum: experience with cantharidin therapy in 300 patients

Silverberg NB, Sidbury R, Mancini AJ. *J Am Acad Dermatol* 2000; 43: 503–7.

A retrospective study of topical cantharidin applied to nonfacial MC for 4 to 6 hours was complicated by the use of other concurrent therapies. Of 300 children, over 90% cleared after a mean of 2.1 treatments; 90% experienced blistering at the treated site, but none developed bacterial infections.

Cantharidin is a topical blistering agent that should be applied by a clinician. Application is directly onto lesions with a blunt wooden end of a cotton swab and occluded to prevent spread. This is then washed off 2 to 6 hours later or at the first sign of blistering. Treatment can be repeated every 2 to 4 weeks until fully resolved. Adverse effects include burning, erythema, pruritus, and dyspigmentation.

Double randomized, placebo-controlled study of the use of topical 10% potassium hydroxide solution in the treatment of molluscum contagiosum

Short KA, Fuller LC, Higgins EM. *Pediatr Dermatol* 2006; 23: 279–81.

A double-randomized, placebo-controlled study in 20 children with 10% potassium hydroxide or normal saline applied twice daily until signs of inflammation: 70% (7/10) of the active group compared with 20% (2/10) of the placebo group achieved complete resolution. This difference was not statistically significant. Dosing studies are required to minimize irritancy.

Five percent or 10% concentrations of potassium hydroxide can be used with frequencies ranging from three times per week to twice daily.

Dermatologists, imiquimod, and treatment of molluscum contagiosum in children: righting wrongs

Katz KA. *JAMA Dermatol* 2015; 151: 125–6.

The use of imiquimod 5% cream for MC has been controversial, as two large unpublished randomized trials of children treated with imiquimod 5% cream or vehicle three times weekly for up to 16 weeks did not show efficacy. The first study showed 24% (52/217) complete clearance rate in the imiquimod group versus 26% (28/106) complete clearance rate in the placebo group. The second study showed a 24% (60/253) versus a 28% (35/126) complete clearance rate in the imiquimod 5% group and placebo group, respectively. This contradicts favorable responses seen in uncontrolled studies and case series, which suggests spontaneous resolution may account for efficacy seen in these studies.

Treatment of molluscum contagiosum in males with an analog of imiquimod 1% cream: a placebo controlled, double-blind study

Syed TA, Goswami J, Ahmadpour OA, Ahmad SA. J Dermatol 1998; 25: 309–13.

One hundred male patients applied either the analog cream or placebo to their mollusca three times daily for 5 days each week for 1 month; 82% cleared with active treatment, compared with 16% of those using placebo. The treatment was well tolerated.

Treatment of molluscum contagiosum with topical diphencyprone therapy

Kang SH, Lee D, Park JH, Cho SH, Lee SS, Park SW. Acta Derm Venereol 2005; 85: 529–30.

Weekly application of 0.0001% diphencyprone in 22 sensitized children over 8 weeks. There was 63.6% complete clearance over a mean treatment period of 5.1 weeks.

Essential oil of Australian lemon myrtle (*Backhousia citriodora*) in the treatment of molluscum contagiosum

Burke BE, Baillie JE, Olson RD. Biomed Pharmacother 2004; 58: 245–7.

Once-daily application of a 10% solution of *Backhousia citriodora* gave over 90% reduction in lesions in 9 of 16 children, compared with none of 16 in the control group (vehicle alone).

Topical cidofovir. A novel treatment for recalcitrant molluscum contagiosum in children infected with human immunodeficiency virus 1

Toro JR, Wood LV, Patel NK, Turner ML. Arch Dermatol 2000; 136:

983–5.

Topical 3% cidofovir applied daily for 5 days per week for 8 weeks cleared previously recalcitrant lesions in two children.

Comparative study of 5% potassium hydroxide solution versus 0.05% tretinoin cream for molluscum contagiosum in children

Rajouria EA, Amatya A, Karn D. Kathmandu Univ Med J 2011; 9: 291–4.

Fifty children were treated with either 5% KOH solution or 0.05% tretinoin cream at bedtime (25 in each group). Both treatments were effective in reducing the lesion count, but response to KOH was quicker. Side effects were less noticeable with tretinoin cream.

Topical retinoids such as tretinoin and adapalene have been tried for MC in small case reports. Frequency can range from every alternate day and titrated up to twice daily as tolerated. Adverse effects include erythema, dryness, and irritation.

Treatment of molluscum contagiosum: a brief review and discussion of a case successfully treated with adapalene

Scheinfeld N. Dermatol Online J 2007; 13: 15.

A single case report of successful topical adapalene therapy.

Combination of essential oil of *Melaleuca alternifolia* and iodine in the treatment of molluscum contagiosum in children

Markum E, Baillie J. J Drugs Dermatol 2012; 11: 349–54.

Fifty-three children were treated with twice-daily essential oil of *Melaleuca alternifolia* (the tea tree) alone (TTO), a combination of *Melaleuca alternifolia* and iodine (TTO-I), or iodine alone. After 30 days 48 children were followed up. There was a 90% reduction in lesions in the TTO-I group—significantly higher than in the other groups.

Treatment of molluscum contagiosum with ingenol mebutate

Javed S, Tying SK. J Am Acad Dermatol 2014; 70: e105.

Single case report of a 4-year-old girl treated with two repeated 3-day applications of ingenol mebutate 0.015% leading to resolution of lesions.

Recalcitrant molluscum contagiosum successfully treated with sinecatechins

Padilla España L, Mota-Burgos A, Martinez-Amo JL, Benavente-Ortiz

F, Rodríguez-Bujaldón A, Hernández-Montoya C. *Dermatol Ther* 2016; 29: 217–8.

Case of a 5-year-old girl with a 2-year history of more than 50 MC lesions, already treated with potassium hydroxide 10% for 1 month. Sinecatechins 10% ointment (derived from green tea) applied twice daily for 4 weeks led to resolution of all lesions with no recurrence at 3-month follow-up.

One-year experience with *Candida* antigen immunotherapy for warts and molluscum

Marron M, Salm C, Lyon V, Galbraith S. *Pediatr Dermatol* 2008; 25: 189–92.

One-year follow-up in 25 of 47 patients with molluscum treated with intralesional *Candida* antigen therapy. There was complete resolution in 56%, partial clearing in 28%, and no improvement in 16%.

Treatment of molluscum contagiosum with oral cimetidine: clinical experience in 13 patients

Dohil M, Prenderville JS. *Pediatr Dermatol* 1996; 13: 310–2.

Thirteen children were treated with a 2-month course of oral cimetidine 40 mg/kg/day. All but three children who completed treatment experienced clearance of all lesions.

Interferon alpha treatment of molluscum contagiosum in immunodeficiency

Hourihane J, Hodges E, Smith J, Keefe M, Jones A, Connett G. *Arch Dis Child* 1999; 80: 77–9.

MC in two children with combined immunodeficiency cleared with subcutaneous interferon- α .

Interferon-alpha treatment of molluscum contagiosum in a patient with hyperimmunoglobulin E syndrome

Kilic SS, Kilicbay F. *Paediatrics* 2006; 117: e1253–5.

Successful treatment with 6 months of subcutaneous interferon- α of MC resistant to multiple therapies in an immunodeficient child.

Resolution of disseminated molluscum contagiosum with highly active antiretroviral therapy (HAART) in patients with AIDS

Calista D, Boschini A, Landi G. *Eur J Dermatol* 1999; 9: 211–3.

Three patients with recalcitrant MC cleared 6 months after commencing HAART.

Morphea

Jack C. O'Brien, and Heidi T. Jacobe

Morphea, also known as *localized scleroderma* (a term that should be discouraged because of unnecessary confusion with systemic sclerosis), is an autoimmune disorder characterized by inflammation and sclerosis of the dermis and in some cases the underlying subcutis, fascia, and muscle. Although previously considered self-limited, a growing body of evidence suggests a remitting relapsing course may be common. Further, untreated lesions may leave behind permanent cosmetic and functional disfigurement, warranting treatment to prevent these sequelae. Morphea has a spectrum of manifestations, ranging from skin only to internal involvement, with musculoskeletal complaints (e.g., synovitis) being the most common extracutaneous manifestation.

Morphea is classified into subtypes, including circumscribed, linear, or generalized. Any subtype may have involvement of the subcutis. Onset is bimodal and can occur in childhood, where linear morphea is most common, or in adults, where circumscribed and generalized predominate.

Notably, morphea is distinct from systemic sclerosis, and there is no progression to systemic sclerosis or involvement of heart, lungs, gastrointestinal tract, or kidneys in morphea. Further, scleroderma hallmark autoantibodies (anticentromere antibody, antitopoisomerase antibody, anti-RNA polymerase III) are absent in morphea, as is Raynaud phenomenon.

Management Strategy

The management of morphea centers first on determining the extent of disease activity and then assessing disease severity, including functional or cosmetic impairment. Active disease is defined as new or expanding lesions with peripheral induration and erythema. An important feature is the depth of involvement. Morphea may be limited to the dermis or involve the subcutis. Recent evidence suggests deeper involvement may have more serious sequelae. Patients with active morphea with involvement of deeper tissues should generally be treated with methotrexate and steroids and not topical therapies, particularly when lesions are extensive or involve cosmetically or functionally sensitive sites. The overarching goal for management of active lesions is to shut down activity to prevent damage.

Patients with en coup de sabre, or hemifacial atrophy, should be assessed for ophthalmologic complaints and referred for an ophthalmologic evaluation of possible subclinical eye involvement. In addition, assess neurologic or dental complaints and refer to a neurologist or dentist if symptoms or abnormalities are noticed. Patients with widespread superficial plaques (particularly in postmenopausal women) require assessment for genital involvement.

Patients with inactive morphea lesions also merit close attention, as studies show inactive disease can have a significant impact on life quality. In this case, multidisciplinary supportive care rather than treatment aimed at eradicating disease activity is warranted.

Once the evaluation is complete, treatment decisions should be based on activity and damage, depth of involvement (dermal vs. deeper tissues), area of involvement, and disease progression. The goal of therapy is to shut down inflammation in active or expanding lesions to avoid long-term sequelae of unchecked active disease.

In general, limited dermal inflammatory lesions that are not rapidly progressing or cosmetically or functionally threatening may be treated with topical therapies (*calcipotriene, calcitriol, tacrolimus, or topical steroids*) or *intralesional triamcinolone*. These patients should be closely followed, and, if their lesions multiply or spread, suppressive therapy is indicated (*phototherapy or methotrexate ± steroids*) to prevent continued development of new lesions. In general, patients with extensive active lesions involving the deep dermis, subcutis, or below, or those with cosmetically or functionally threatening lesions such as en coup de sabre or hemifacial atrophy, should receive methotrexate and systemic steroids. Widespread active morphea limited to the dermis may be treated with *phototherapy, preferably UVA 1, or, if unavailable, UVA without psoralen or narrowband UVB*. Serial photography and skin scores are invaluable to determine response to treatment. The goal of therapy is to prevent progression of existing lesions and abrogate inflammation. Complete resolution of lesions does not occur (unless lesions are very early) and should not be considered a therapeutic end point.

In addition to treating active disease, it is imperative to assess for features of disease damage, as these have been shown to have significant impairment in quality of life for patients with morphea. Patients with limitation in range of motion, contracture, or weakness in an affected limb should be referred to occupational or physical therapy. In cases where limb length discrepancy is suspected, refer to

prosthetics and orthotics for shoe inserts. For deep lesions in cosmetically sensitive areas (e.g., en coup de sabre), referral to plastic surgery can be offered as long as disease is stable and inactive.

The evidence currently does not support the use of topical steroids, oral or topical calcipotriol, D-penicillamine, interferon- γ , or antimalarials. Therefore the use of these treatments is discouraged in severe cases of morphea where function or cosmesis is threatened. Penicillamine also has a significant side effect profile, including nephrotoxicity, and should be avoided.

Specific Investigations

- Localized Scleroderma Cutaneous Assessment Tool (LoSCAT)
- Serial digital photography
- Histopathology
- Ultrasound and Doppler ultrasound
- Magnetic resonance imaging (MRI)

Development of consensus treatment plans for juvenile localized scleroderma

Li SC, Torok KS, Pope E, Dedeoglu F, Hong S, Jacobe HT, et al. *Arthritis Care Res (Hoboken)* 2012; 64: 1175–85.

This paper outlines the consensus evaluation and treatment plans for juvenile moderate to severe morphea as determined by a focus group with expertise in morphea and the current literature.

The Localized Scleroderma Cutaneous Assessment Tool: responsiveness to change in a pediatric clinical population

Kelsey CE, Torok KS. *J Am Acad Dermatol* 2013; 69: 214–20.

This is a validation study for the LoSCAT demonstrating that the mLoSSI, the activity measure of the LoSCAT, is a valid and responsive measure of disease activity of morphea in children.

The use of Doppler ultrasound to evaluation lesions of localized scleroderma

Li SC, Liebling MS. *Curr Rheumatol Rep* 2009; 11: 205–11.

Disease-related structural changes, such as tissue thickening, atrophy, and architectural alterations, can be readily detected using ultrasound. High spatial resolution enables monitoring of changes in

tissue thickness over the course of disease and treatment, offering another method to document therapeutic efficacy in the hands of an experienced ultrasonographer.

MRI findings in deep and generalized morphea (localized scleroderma)

Horger M, Fierlbeck G, Kuemmerle-Deschner J, Tzaribachev N, Wehrmann M, Claussen C, et al. Am J Roentgenol 2008; 190: 32–9.

This paper describes MRI findings in morphea. MRI allows for establishment of the depth of involvement and degree of activity based on signal intensity. This article also provides images of MRI findings in morphea.

First-Line Therapies

Extensive dermal lesions

• Phototherapy: BB-UVA, NB-UVB, UVA1	A
--------------------------------------	----------

Moderate to severe morphea/deep involvement

• Methotrexate + IV corticosteroids	C
• Methotrexate + oral steroids	A

Limited dermal lesions

• Topical tacrolimus under occlusion	C
• Intralesional steroids	C

One limited deep lesion

A systematic review of morphea treatments and therapeutic algorithm

Zwischenberger BA, Jacobe HT. J Am Acad Dermatol 2011; 65: 925–41.

An evaluation and treatment algorithm is proposed for all types of morphea based on current literature and expert opinion.

Update on morphea part II. Outcome measures and treatment

Fett N, Werth VP. J Am Acad Dermatol 2011; 64: 231–42.

The authors discuss outcome measures and treatment options and provide algorithms for treatment of generalized, linear, and limited plaque morphea.

A randomized controlled study of low-dose UVA1, medium-dose UVA1, and narrowband UVB phototherapy in the treatment of localized scleroderma

Kreuter A, Hyun J, Stucker M, Sommer A, Altmeyer P, Gambichler T. J Am Acad Dermatol 2006; 54: 440–7.

Low- and medium-dose UVA1 (20 and 50 J/cm²) was compared with narrowband (NB) UVB in a randomized trial. All patients showed a significant decrease in skin scores. Medium-dose UVA1 had a significantly greater decrease compared with NB-UVB; there were no differences between low-dose UVA1 and NB-UVB.

Medium-dose is more effective than low-dose ultraviolet A1 phototherapy for localized scleroderma as shown by 20-MHz ultrasound assessment

Sator PG, Radakovic S, Schulmeister K, Hönigsmann H, Tanew A. J Am Acad Dermatol 2009; 60: 786–91.

Ultrasound-measured dermal thickness was the primary outcome measure in this randomized controlled trial (RCT) comparing low (20 J/cm²) and high dose (70 J/cm²). High doses resulted in significant decrease in dermal thickness measured by ultrasound but no significant differences in clinical score.

Different low doses of broad-band UVA in treatment of morphea and systemic sclerosis

El-Mofty M, Mostafa W, El-Darouty M, Bosseila M, Nada H, Yousef R, et al. *Photodermatol Photoimmunol Photomed* 2004; 20: 148–56.

Sixty-three patients with both progressive systemic sclerosis and morphea were treated with various doses of UVA without psoralen. Results were similar between 5, 10, and 20 J/cm². This offers a more widely available alternative to UVA1.

Methotrexate treatment in juvenile localized scleroderma: a randomized, double-blinded, placebo-controlled trial

Zulian F, Martini G, Vallongo C, Cittadello F, Falcini F, Patrizi A, et al. *Arthritis Rheum* 2011; 63: 1998–2006.

Seventy patients were randomized to receive oral methotrexate (15 mg/m², maximum 20 mg) or placebo once weekly for 12 months. Both groups received oral prednisone (1 mg/kg/day, maximum 50 mg) for the first 3 months. Using a composite outcome measure, the methotrexate treatment group had a higher rate of remission and less recurrence. This is the first randomized placebo-controlled trial to demonstrate efficacy in the treatment of morphea.

Pulsed high-dose corticosteroids combined with low-dose methotrexate in severe localized scleroderma

Kreuter A, Gambichler T, Breuckmann F, Rotterdam S, Freitag M, Stuecker M, et al. *Arch Dermatol* 2005; 141: 847–52.

Methotrexate 15 mg/week plus intravenous methylprednisolone 100 mg/day for 3 days per month was administered to 15 adults. Fourteen of 15 improved, and no correlation was found between duration of disease and response to treatment.

Localized scleroderma: response to occlusive treatment with tacrolimus ointment

Mancoso G, Berdondini RM. *Br J Dermatol* 2005; 152: 180–2.

Tacrolimus 0.1% ointment applied twice daily to a target plaque and occluded was compared with petrolatum in seven adults. Early inflammatory lesions resolved and late sclerotic lesions softened, without improvement in atrophy and scarring.

Efficacy of topical tacrolimus 0.1% in active plaque morphea: randomized, double-blind, emollient-controlled pilot study

Kroft EB, Groeneveld TJ, Seyger MM, de Jong EM. Am J Clin Dermatol 2009; 10: 181–7.

In this randomized, double-blind, emollient-controlled study of 10 patients with active plaque morphea, the authors concluded that topical tacrolimus applied twice a day for 12 weeks effectively decreases skin thickness, dyspigmentation, erythema, telangiectasia, and atrophy.

Second-Line Therapies

Extensive dermal lesions

• PUVA (bath or cream)	B
------------------------	----------

Moderate to severe morphea

• Mycophenolate mofetil	C
• Abatacept	D

Limited dermal lesions

• Imiquimod	C
• Calcipotriene under occlusion	
• Calcipotriol–betamethasone	C
• Pirfenidone 8% gel	D

UVA/UVA1 phototherapy and PUVA photochemotherapy in

connective tissue disease and related disorders: a research based review

Breuckmann F, Gambichler T, Altmeyer P, Kreuter A. *BMC Dermatol* 2004; 4: 11.

These authors systematically review the literature on UVA/UVA1 and PUVA therapy in various skin conditions, including morphea, and conclude that significant softening of the skin occurs with all modalities used.

Successful treatment of severe or methotrexate-resistant juvenile localized scleroderma with mycophenolate mofetil

Martini G, Ramanan AV, Falcini F, Girschick H, Goldsmith DP, Zulian F. *Rheumatology (Oxford)* 2009; 48: 1410–3.

Ten children with morphea already taking methotrexate and systemic steroids with limited improvement had mycophenolate mofetil added to their treatment. Nine of the 10 patients reported improvement.

First case series on the use of calcipotriol-betamethasone dipropionate for morphoea

Dytoc MT, Kossintseva I, Ting PT. *Br J Dermatol* 2007; 157: 615–8.

Calcipotriol in combination with betamethasone dipropionate was reported to have efficacy in the treatment of morphea in a prospective study of six patients with plaque morphea.

Topical calcipotriene for morphea/linear scleroderma

Cunningham BB, Landells ID, Langman C, Sailer DE, Paller AS. *J Am Acad Dermatol* 1998; 39: 211–5.

Uncontrolled trial evaluated topical calcipotriene 0.005% ointment applied under occlusion to active target lesions twice daily. All 12 patients showed significant decrease in subjective/clinical sclerosis scales.

First case series on the use of imiquimod for morphoea

Dytoc M, Ting PT, Man J, Sawyer D, Fiorillo L. *Br J Dermatol* 2005; 153: 815–20.

The authors used 5% imiquimod cream, an inducer of interferon- γ known to inhibit TGF- β , to treat 12 patients. Dyspigmentation, induration, and erythema improved. The histology of the skin showed a reduction of dermal thickness.

Pirfenidone gel in patients with localized scleroderma: a phase II study

Rodriguez-Castellano M, Tlacuilo-Parra A, Sanchez-Enriquez S, Velez-Gomez E, Guevara-Gutierrez E. *Arthritis Res Ther* 2014; 16: 510.

This was an open-label trial of pirfenidone 8% gel applied three times a day for 6 months in adults with morphea. The authors report the mLoSSI score was improved at 3 and at 6 months from baseline and there was histologic improvement.

Third-Line Therapies

• Ciclosporin	E
• Infliximab	E

Combining UVA therapy with systemic immunosuppressives to treat progressive diffuse morphoea

Rose RF, Goodfield MJ. *Clin Exp Dermatol* 2005; 30: 226–8.

The authors discuss the various treatments used in morphea and comment that combination therapies may hold promise. Of note, ciclosporin and mycophenolate should not be used in combination with PUVA due to risk of photocarcinogenesis.

Good response to linear scleroderma in a child to ciclosporin

Strauss RM, Bhushan M, Goodfield MJ. *Br J Dermatol* 2004; 150: 790–2.

A 12-year-old child with rapidly expanding linear morphea was first treated with clobetasol twice a day. Because there was little improvement in her condition, ciclosporin 3 mg/kg daily was added to the regimen with rapid improvement and softening of the lesion on her thigh.

A case report of successful treatment of recalcitrant childhood localized scleroderma with infliximab and leflunomide

Ferguson ID, Weiser P, Torok KS. Open Rheumatol J 2015; 9: 30–5.

A 14-year-old female with severe progressive morphea was treated with infliximab and then leflunomide after not tolerating methotrexate with steroids and mycophenolate mofetil. She had improvement in mLoSSI, joint function, and global assessment. The authors felt the improvement was largely due to infliximab.

Mucoceleles

Noah Scheinfeld

Labial mucoceles fall into two categories: the mucous extravasation cyst and the mucous retention cyst. The mucous extravasation cyst describes a false cyst because the mucous extravasation cyst lacks an epithelial lining arising from the partially or totally severed salivary gland duct, resulting in the accumulation of saliva in the adjacent soft tissue. At this point the mucocele is cut off by a fibrous connective tissue pseudocapsule. Ductal epithelium lines the mucous retention cyst. The mucous retention cyst develops from partial obstruction of a duct in the presence of the salivary gland's continued mucus

secretion. The extravasation mucocele manifests most commonly and on the young person's lower lip. The retention mucocele is more apt to occur on the buccal cheek or soft palate of an older patient.

To expand this further, mucous extravasation cysts arise from trauma to salivary gland ducts. This trauma leads to rupture of ducts and leakage of mucin from the minor salivary glands. The mucin subsequently forms pseudocystic aggregations, most commonly on the lower lip. These aggregations are referred to as *mucoceles*.

Mucoceles manifest with a variety of tones and color that range from flesh color to red to translucent blue. The shape of mucoceles is round or oval, and their surface is smooth. They usually possess a soft, fluctuant, or gel-like consistency. Single or multiple mucoceles can manifest and can range from 0.1 to 2 cm in diameter. A variant of a mucocele termed *superficial mucocele* can manifest on the palate, retromolar pad, and posterior buccal mucosa as single or multiple vesicles, which can break down into an ulcer. Despite healing after a few days, superficial mucoceles recur often in the same location. A mucocele is termed a *ranula* when on the floor of the mouth, and an *epulis* when on the gums.

Management Strategy

The natural history of mucoceles can involve their expansion and periodic rupture and sometimes spontaneous resolution. There is some morbidity associated with mucoceles that ranges from discomfort to suboptimal cosmetic appearance of a nodule with a hardened consistency due to scarring and tissue consolidation.

A clinical diagnosis can be supported, when necessary, by histology and ultrasound imaging. In addition to conservative treatment, a range of surgical and other techniques can be employed.

Specific Investigations

- Biopsy
- Doppler ultrasonography
- Color Doppler imaging

First-Line Therapies

• Cryotherapy	C
• Intralesional corticosteroids	D
• Do nothing	D

A simple cryosurgical method for treatment of oral mucous cysts

Toida M, Ishimaru JI, Hobo N. *Int J Oral Maxillofac Surg* 1993; 22: 353–5.

Twelve female and six male patients with mucous cysts on the lower lip and the tip of the tongue were treated by direct application of liquid nitrogen with a cotton swab. Each lesion was exposed to four or five cycles composed of freezings of 10 to 30 s and thawings of double the freezing times. No anesthesia was required. All lesions had disappeared completely 2 to 4 weeks after one or two treatment courses of cryosurgery. In all cases, neither scarring nor recurrence was noted during the 6 months to 5 years of follow-up.

Histopathology of mucoceles infiltrated with steroids

Merida FMT. *Med Cutan Ibero Lat Am* 1976; 4; 15–8.

Eight cases of lip mucocele with intralesional infiltration of triamcinolone acetonide (Kenacort). In three cases there was complete regression of the lesion after a variable period between the first and the fourth infiltration. In five cases the results were negative. The patients who reacted positively to treatment were followed up for a year afterward.

A review of common pediatric lip lesions: herpes simplex/recurrent herpes labialis, impetigo, mucoceles, and hemangiomas

Bentley JM, Barankin B, Guenther LC. *Clin Pediatr* 2003; 42: 475–82.

After a diagnosis is made, treatment is often not needed as smaller and more superficial mucoceles are likely to rupture and spontaneously heal. The patient's future as it relates to mucoceles is

good whether or not surgery is involved.

Clinical characteristics, treatment, and evolution of 89 mucocoeles in children

Mínguez-Martínez I, Bonet-Coloma C, Ata-Ali-Mahmud J, Carrillo-García C, Peñarrocha-Diago M, Peñarrocha-Diago M. J Oral Maxillofac Surg 2010; 68: 2468–71.

In a series of 89 cases, mucocoeles were more commonly located on the lower lip; 43.8% resolved spontaneously, and 8% of the surgically removed mucocoeles reappeared.

Second-Line Therapy

• Punch biopsy

E

Two simple treatments for lower lip mucocoeles

Gill D. Australas J Dermatol 1996; 37: 220.

Punch is a useful technique for treating mucocoele and has the added benefit of providing a histologically certain diagnosis.

Third-Line Therapies

• CO ₂ laser	B
• Surgical excision	B
• Marsupialization	D
• Micromarsupialization	D
• Nonablative lasers	E

Treatment of mucocele of the lower lip with carbon dioxide laser

Huang IY, Chen CM, Kao YH, Worthington P. J Oral Maxillofac Surg 2007; 65: 855–8.

Eighty-two patients with biopsy-confirmed mucocele of the lower lip were treated with CO₂ laser vaporization with no bleeding and minimal scar formation. There were two recurrences. Researchers noted mild discomfort and rare complications. At the operative site, one patient felt temporary numbness. Due to the fact that the operative time is shorter than for excision, carbon dioxide laser appears useful for children and for less cooperative patients.

Clinicostatistical study of lower lip mucocèles

Yamasoba T, Tayama N, Syoji M, Fukuta M. Head Neck 1990; 12: 316–20.

Researchers reported 70 patients with lower lip mucocèles for patient characteristics, clinical features, and histopathologic findings. Patients were divided almost equally between males and females, with ages ranging from 2 to 63 years, with the highest incidence of lesions occurring in the second decade. Mucocele life span ranged a few days to 3 years. Size did not affect outcome. The upper lateral incisor was the most commonly involved area. Of 70 biopsies, 68 were mucous extravasation cysts and 2 were mucous retention cysts. Surgical excision was the treatment of choice, with recurrence of the

lesion in only two cases.

Conventional surgical treatment of oral mucocoele: a series of 23 cases

Bahadure RN, Fulzele P, Thosar N, Badole G, Baliga S. Eur J Paediatr Dent 2012; 13: 143–6.

Conventional surgical procedure with excision of minor salivary glands was effective in 23 patients and was considered with 3-year follow-up to have a low recurrence rate.

Clinical and histopathologic study of salivary mucocoeles

Kang SK, Kim KS. Taehan Chikkwa Uisa Hyophoe Chi 1989; 27: 1059–71.

In a series of 112 patients, surgeons treated 107 mucocoeles (95%) by excision and only 5 by marsupialization. Eighteen of 112 cases (16%) recurred. Only 3 of the 112 cases revealed an epithelial lining. This incidence indicates that the mucus extravasation by damage of excretory duct rather than the ductal dilatation by mucus retention may play a critical role in the production of these lesions. In 81 cases (72.3%) minor salivary glands were included in the excision biopsy specimen.

Treatment of mucus retention phenomena in children by the micromarsupialization technique: case reports

Delbem AC, Cunha RF, Vieira AE, Ribeiro LL. Pediatr Dent 2000; 22: 155–8.

Micromarsupialization requires neither injections nor surgery and was studied in 14 patients. Micromarsupialization basically involves placing a topical anesthetic gel on the mucocoele for 3 minutes, passing a 4 to 0 silk suture through the body of the mucocoele, and tying a surgeon's knot. The suture material is removed 7 days later, at which time the mucocoele is resolved. The advantages of this technique include simplicity and relative lack of pain. Micromarsupialization is not indicated for fibrotic lesions, lesions of the palate, or lesions inside of the cheek. Of the original 14 patients treated by the micromarsupialization technique, 12 presented full regression 1 week after treatment. Two cases recurred.

Excision of oral mucocoele by different wavelength lasers

Romeo U, Palaia G, Tenore G, Del Vecchio A, Nammour S. Indian J

Dent Res 2013; 24: 211–5.

In three cases excision was performed using two different techniques (circumferential incision technique and mucosal preservation technique) and three different laser wavelengths (Er, Cr:YSGG 2780 nm, diode 808 nm, and KTP 532 nm). All the tested lasers, regardless of wavelength, showed many advantages (bloodless surgical field, no postoperative pain, relative speed, and easy execution). The most useful surgical technique depends on clinical features of the lesion.

Mucocele of the minor salivary glands in an infant: treatment with diode laser

Paglia M, Crippa R, Ferrante F, Angiero F. Eur J Paediatr Dent 2015; 16: 139–42.

A report of one case of mucocele in a 3-month-old infant in the right labial commissure noted excision by diode laser of different wavelengths (635–980 nm), with an average power of 1.8 W, in continuous wave mode, using 300- to 320-micron optical fibers. The healing occurred in 10 days. There were no adverse effects, and the patient was carefully followed up until complete healing.

Mucous membrane pemphigoid

Caroline Allen, and Vanessa Venning

Mucous membrane pemphigoid (MMP) formerly known as *cicatricial pemphigoid*, is a heterogeneous group of chronic acquired autoimmune subepidermal blistering diseases. It is characterized by blistering and erosions of one or more mucous membranes (eyes, oral

mucosa, esophagus, genitals) and to a lesser extent the skin. This may lead to permanent scarring of the affected area, particularly the conjunctiva.

Management Strategy

MMP is a chronic disease and does not generally remit spontaneously; disease activity will fluctuate without treatment, and treatments are disease modifying rather than curative.

Optimal treatment for MMP is unclear as there is little evidence in the form of randomized control trials; international consensus guides treatment strategy, based on the site, severity, extent, and rate of progression of disease. Patient comorbidities must also be considered, and a multidisciplinary approach is vital.

World Workshop on Oral Medicine VI: a systematic review of the treatment of mucous membrane pemphigoid

Taylor J, McMillan R, Shephard M, Setterfield J, Ahmed R, Carrozzo M; et al. Oral Surg Oral Med Oral Pathol Oral Radiol 2015; 120: 161–71.e20.

Interventions for mucous membrane pemphigoid and epidermolysis bullosa aquisitia

Kirtshig G, Murrell D, Wojnarowska F, Khumalo N. Cochrane Database Syst Rev 2003; CD004056.

The first international consensus on mucous membrane pemphigoid: definition, diagnostic criteria, pathogenic factors, medical treatment and prognostic indicators

Chan LS, Ahmed AR, Anhalt GJ, Bernauer W, Cooper KD, Elder MJ, et al. Arch Dermatol 2002; 138: 370–9.

Specific Investigations

For diagnosis

- Direct immunofluorescence
- Indirect immunofluorescence on salt split skin

For treatment

- Complete blood count (CBC), liver function tests (LFTs), renal function
- Glucose 6 phosphate dehydrogenase (G6PD) activity
- Thiopurine methyltransferase (TPMT)

First-Line Therapies

• Topical corticosteroids	C
• Dapsone	C
• Antiinflammatory antibiotics	D
• Systemic corticosteroids	C
• Cyclophosphamide	C

Mild disease

The management of oral mucous membrane pemphigoid with dapsone and topical corticosteroid

Arash A, Shirin L. J Oral Pathol Med 2008; 37: 341–4.

Five patients with mild MMP had a good response to triamcinolone in orobase.

Treatment of severe erosive gingival lesions by topical application of clobetasol propionate in custom trays

Gonzales-Moles MA, Ruiz Avila I, Rodriguez-Archilla A, Morales-Garcia P, Mesa-Aguado F, Bascones-Martinez A, et al. Oral Surg Oral Med Oral Pathol Oral Radiol Endodont 2003; 95: 688–92.

Improvement in all 22 patients with oral MMP treated with topical clobetasol propionate with nystatin applied via a gingival tray.

Treatment-resistant or severe disease

Dapsone efficacy and adverse events in the management of mucous membrane pemphigoid

Hegarty AM, Ormond M, Sweeney M, Hodgson T. Eur J Dermatol 2010; 20: 223–4.

Eight out of 20 patients improved with dapsone. One failed to respond, and 11 developed side effects necessitating cessation.

The management of oral mucous membrane pemphigoid with dapsone and topical corticosteroid

Arash A, Shirin L. J Oral Pathol Med 2008; 37: 341–4.

All 15 patients had a significant response to topical corticosteroids and dapsone 25 to 100 mg daily. Ten had complete resolution.

Dapsone therapy of cicatricial pemphigoid

Rogers RS III, Mehregan DA. Semin Dermatol 1988; 7: 201–5.

Seventy-seven patients with oral, ocular or generalized MMP benefited from either 150 mg dapsone per day or 1500 to 3000 mg sulfapyridine per day for at least 12 weeks.

Sulphamethoxypyridazine for dermatitis herpetiformis, linear IgA disease and cicatricial pemphigoid

McFadden JP, Leonard JN, Powles AV, Rutman AJ, Fry L. et al. Br J Dermatol 1989; 121: 759–62.

Sulfamethoxypyridazine 500 to 1500 mg was partially effective in 10 of 15 patients with oral and generalized MMP.

Treatment with dapsone 50 to 200 mg/daily and sulfonamides 500 to 1500 mg sulfapyridine or sulfamethoxypyridazine is effective in some patients.

Antiepileptic cicatricial pemphigoid of the larynx successfully treated with a combination of tetracycline and niacinamide

Sakamoto K, Mori K, Hashimoto T, Yancey KB, Nakashima T. Arch Otolaryngol Head Neck Surg 2002; 128: 1420–3.

Successful therapy with tetracycline and nicotinamide in cicatricial pemphigoid

Kreyden OP, Borradori L, Trueb RM, Burg G, Nestle FO. Hautarzt 2001; 52: 247–50.

Single case reports of effective treatment with tetracycline 1500 mg/day and nicotinamide (500–3000 mg/day).

Systemic minocycline as a therapeutic option in predominantly oral mucous membrane pemphigoid: a cautionary report

Carrozzo M, Arduino P, Bertolusso G, Cozzani E, Parodi A. Int J Oral Maxillofac Surg 2009; 38: 1071–6.

Seven of nine patients with oral disease responded to minocycline 200 mg/day; however, side effects limited treatment in five.

Combination therapy with nicotinamide and tetracyclines for cicatricial pemphigoid: further support for its efficacy

Reiche L, Wojnarowska F, Mallon E. Clin Exp Dermatol 1998; 23: 254–7.

Minocycline 50 to 100 mg/day combined with 2.5 to 3 g nicotinamide per day was beneficial in five of eight patients.

Antiinflammatory antibiotics can be of benefit. Side effects may limit treatment. Nicotinamide may confer additional protection.

Mucous membrane pemphigoid. Treatment experience at two institutions

Lamey PJ, Rees TD, Binnie WH, Rankin KV. Oral Surg Oral Med Oral Pathol 1992; 74: 50–3.

Fourteen patients with oral MMP were treated with a combination of systemic and topical steroids: eight became asymptomatic, five improved, and one was unchanged.

Cicatricial pemphigoid: a re-evaluation of therapy

Nayar M, Wojnarowska F. J Dermatol Treat 1993; 4: 89–93.

Five of 15 patients with generalized MMP benefited from prednisolone 40 to 60 mg/day, but it was ineffective in oral disease.

Treatment with systemic corticosteroids seems helpful at doses of prednisolone 0.5 to 2 mg/kg/day. Most studies used a combination of systemic steroids and a steroid-sparing drug; a small randomized trial supported combination treatment in ocular MMP (see later).

Cyclophosphamide for ocular inflammatory diseases

Pujari SS, Kempen JH, Newcomb CW, Gangaputra S, Daniel E, Suhler EB, et al. Ophthalmology 2010; 117: 356–65.

Retrospective cohort study of 98 patients with MMP treated with

cyclophosphamide (75–150 mg/daily) and oral prednisolone. Forty-two patients achieved complete remission within 6 months, increasing to 67 at 1 year.

Management of ocular mucous membrane pemphigoid with immunosuppressive therapy

Thorne JE, Woreta FA, Jabs JA, Anhalt GJ. Ophthalmology 2008; 115: 2146–52.

Retrospective cohort study. Forty out of 44 patients treated with cyclophosphamide (2 mg/kg/day) and prednisolone (initially 1 mg/kg/day tapering over 1–2 months) achieved remission within 2 years; 5 subsequently relapsed.

Analysis of a novel protocol of pulsed intravenous cyclophosphamide for recalcitrant or severe ocular inflammatory disease

Suelves AM, Arcinue CA, González-Martín JM, Kruh JN, Foster CS. Ophthalmology 2013; 120: 1201–9.

Retrospective case series of 65 patients (110 eyes) of patients with ocular disease treated with pulsed intravenous cyclophosphamide (starting dose 1 g/m² body surface area [BSA] in 1000 mL saline over 1 hour; subsequent doses calculated based on hemogram by absolute numbers) in combination with methylprednisolone (1000 mg in 1000 mL normal saline over 1 hour). Complete remission was achieved in 54 patients (84%).

Oral cyclophosphamide without corticosteroids to treat mucous membrane pemphigoid

Munyangango EM, Le Roux-Villet C, Doan S, Pascal F, Soued I, Alexandre M, et al. Br J Dermatol 2013; 168: 381–90.

Retrospective case series of 13 patients with severe refractory MMP. Oral cyclophosphamide (2 mg/kg/day) without corticosteroids was commenced on a background of previous treatments (dapsone, sulfasalazine, or topicals) in the absence of corticosteroids. Nine out of 13 patients responded to treatment, with 7/13 achieving complete remission, 4 of whom maintained this at 6 months after the study. Ten out of 13 patients suffered lymphopenia, leading to withdrawal of cyclophosphamide in 6/13.

In patients with severe ocular disease combination treatment with cyclophosphamide (oral or intravenous) and prednisolone is first line; oral

and intravenous treatments seem equally effective. Cyclophosphamide has been shown to be effective in the absence of corticosteroids. In mild to moderate MMP, dapsone in combination with corticosteroids may be used first line.

Second-Line Therapies

• Topical mitomycin	C
• Mycophenolate mofetil	C
• Azathioprine	D
• Methotrexate	D
• Ciclosporin	D

Intraoperative mitomycin C in the treatment of cicatricial obliterations of conjunctival fornices

Secchi AG, Tognon MS. Am J Ophthalmol 1996; 122: 728–30.

Intraoperative topical mitomycin was useful in 4/4 patients.

Subconjunctival mitomycin C for the treatment of ocular cicatricial pemphigoid

Donnenfeld ED, Perry HD, Wallerstein A, Caronia RM, Kanellopoulos AJ, Sforza PD, et al. Ophthalmology 1999; 106: 72–9.

No disease progression occurred in 8/9 eyes treated with subconjunctival mitomycin C.

Ocular cicatricial pemphigoid review

Foster CS, Sainz De La Maza M. Curr Opin Allergy Clin Immunol 2004; 4: 435–9.

Subconjunctival mitomycin did not prevent progression of scarring.
The benefit of mitomycin is uncertain.

Mycophenolate mofetil for ocular inflammation

Daniel E, Thorne JE, Newcomb CW, Pujari SS, Kaçmaz RO, Levy-Clarke GA, et al. Am J Ophthalmol. 2010; 149: 423–32.

Retrospective cohort study of 18 patients with ocular MMP treated with mycophenolate mofetil in combination with prednisolone. Forty-one percent achieved complete control at 6 months, increasing to 71% at 1 year; most relapsed on discontinuation of prednisolone, but the authors report a steroid-sparing effect. Doses were not specified.

Long-term results of therapy with mycophenolate mofetil in ocular mucous membrane pemphigoid

Doycheva D, Deuter C, Blumenstock G, Stuebiger N, Zierhut M. Ocul Immunol Inflamm 2011; 19: 431–8.

Retrospective study of 10 patients (19 eyes) with ocular MMP treated with mycophenolate mofetil (1 g/day) with prednisolone (initially 1 mg/kg/day, tapered to 5 mg/day). Control of inflammation achieved in 58% (11/19 eyes). Progression was prevented in 47% (9/19 eyes).

Treatment of mucous membrane pemphigoid with mycophenolate mofetil

Nottage JM, Hammersmith KM, Murchison AP, Felipe AF, Penne R, Raber I. Cornea 2013; 32: 810–5.

Retrospective case series of 23 consecutive patients with ocular disease. Sixteen patients achieved control with mycophenolate as monotherapy, a further 3 in combination with other treatments. Treatment was stopped in 5 patients; in 4 this was due to failure to obtain inflammatory control, and the fifth suffered an adverse reaction.

Treatment of mucous membrane pemphigoid with the combination of mycophenolate mofetil, dapsone, and prednisolone: a case series

Staines K, Hampton PJ. Oral Surg Oral Med Oral Pathol Oral Radiol 2012; 114: e49–56.

Six patients with skin and oral disease treated with mycophenolate mofetil (1–1.5 g/day) with dapsone 50 mg and prednisolone 0.5

mg/kg/day. At 18 months all had complete resolution of skin, oral, and pharyngeal disease.

Cicatricial pemphigoid: treatment with mycophenolate mofetil

Ingen-Housz-Oro S, Prost-Squarcioni C, Pascal F, Doan S, Brette MD, Bachelez H, et al. *Ann Dermatol Venereol* 2005; 132: 13–6.

Mycophenolate mofetil (1.5 g/day or 2 g/day) helped to control the disease in 10 of 14 patients; most also received cyclophosphamide or dapsone.

Immunosuppressive therapy for ocular mucous membrane pemphigoid strategies and outcomes

Saw VP, Dart JK, Rauz S, Ramsay A, Bunce C, Xing W, et al. *Ophthalmology* 2008; 115: 253–61.e1.

In a retrospective noncomparative study of 115 patients, azathioprine 1 to 2.5 mg/kg daily was effective in 47%. Side effects limited treatment in 40%. Combination of sulfur/steroid/myelosuppressive may be superior to single therapy. Control of inflammation does not necessarily prevent progression.

Azathioprine for ocular inflammatory diseases

Pasadhika S, Kempen JH, Newcomb CW, Liesegang TL, Pujari SS, Rosenbaum JT, et al. *Am J Ophthalmol* 2009; 148: 500–9.

Retrospective cohort of 33 patients with ocular disease treated with azathioprine and oral prednisolone. Forty-four percent achieved control by 6 months, with 12% off prednisolone treatment. This increased to 67% controlled by 1 year, with 17% off prednisolone. Doses were not specified.

Methotrexate for ocular inflammatory diseases

Gangaputra S, Newcomb CW, Liesegang TL, Kaçmaz RO, Jabs DA, Levy-Clarke GA, et al; Systemic Immunosuppressive Therapy for Eye Diseases Cohort Study. *Ophthalmology* 2009; 116: 2188–98.

Retrospective cohort study of 58 patients with ocular MMP. A reported 39.5% achieved complete control of inflammation at 6 months, increasing to 65.0% at 1 year with 26.8% off prednisolone at 1 year. Doses of methotrexate were not specified.

Methotrexate therapy for ocular cicatricial pemphigoid

McCluskey P, Chang JH, Singh R, Wakefield D. *Ophthalmology* 2004;

111: 796–801.

In 12 of 17 patients with mainly ocular MMP oral methotrexate (and topical treatment) prevented progression of scarring. Methotrexate was given orally as a single weekly dose at a starting dose of 5 to 15 mg determined empirically and approximately based on body weight.

Cyclosporine for ocular inflammatory diseases

Kaçmaz RO, Kempen JH, Newcomb C, Daniel E, Gangaputra S, Nussenblatt RB, et al. Ophthalmology 2010; 117: 576–84.

Ciclosporin was minimally effective even at doses in excess of 3.5 mg/kg/day. All patients remained on corticosteroids.

Ocular autoimmune pemphigoid and cyclosporine

Alonso A, Bignone ML, Brunzini M, Brunzini R. Allergol Immunopathol (Madr) 2006; 34: 113–5.

Treatment-resistant ocular pemphigoid in 82 patients was treated with ciclosporin 100 mg/day, with an attendant reduction in the dose of steroids.

There is evidence that the immunosuppressive agents are effective. Mycophenolate mofetil 0.5 to 1 g twice daily and azathioprine 1 to 3 mg/kg/day are used most frequently. Methotrexate 5 to 25 mg/week and ciclosporin 2 to 4 mg/kg/day are less widely used.

Third-Line Therapies

• Intravenous immunoglobulins	C
• Plasmapheresis	E
• Rituximab	D
• Etanercept	E
• Infliximab	E
• Topical tacrolimus	E
• Pentoxifylline	C
• Colchicine	E
• Low-level laser	E

Consensus statement on the use of intravenous immunoglobulin therapy in the treatment of autoimmune mucocutaneous blistering diseases

Ahmed AR, Dahl MV. Arch Dermatol 2003; 139: 1051–9.

Good review on uses and regimens.

Treatment of epidermolysis bullosa acquisita with intravenous immunoglobulin in patients non-responsive to conventional therapy: clinical outcome and post-treatment long-term follow-up

Ahmed AR, Gürcan HM. J Eur Acad Dermatol Venereol 2012; 26: 1074–83.

Retrospective case series of 10 patients with epidermolysis bullosa acquisita (EBA), 7 of whom had mucosal disease. Intravenous immunoglobulin (IVIG) was used as monotherapy with 2 g/kg/cycle given over 3 days initially monthly, then tapering. Complete clinical response occurred in all with prolonged remission.

Intravenous immunoglobulins and mucous membrane pemphigoid

Mignogna MD, Leuci S, Piscopo R, Bonovolontà G. Ophthalmology 2008; 115: 752.

IVIG treatment was beneficial in six patients with generalized MMP also affecting the eyes.

IVIG at doses 0.5 to 2 g/day (over 3–5 days) initially once monthly is justified in rapidly progressive or recalcitrant disease, either in combination with other treatments or as monotherapy.

Combination of rituximab and intravenous immunoglobulin for recalcitrant ocular cicatricial pemphigoid: a preliminary report

Foster CS, Chang PY, Ahmed AR. Ophthalmology 2010; 117: 861–9.

Six patients were treated with a combination of IVIG and rituximab. Disease progression was arrested in all six.

A dose of 375 mg/m² of rituximab was given once weekly for 8 consecutive weeks. Thereafter, for the subsequent 4 months, it was given once monthly

The dose of IVIG was 2 g/kg per cycle. The total dose was divided into three equal parts on 3 consecutive days. The frequency of the IVIG was monthly until the B-cell level returned to normal. Thereafter, IVIG was continued, and the intervals between infusions were increased to 6, 8, 10, 12, 14, and 16 weeks. The last cycle was given at the 16-week interval.

Rituximab for treatment-refractory pemphigus and pemphigoid: a case series of 17 patients

Kasperkiewicz M, Shimanovich I, Ludwig RJ, Rose C, Zillikens D, Schmidt E. J Am Acad Dermatol 2011; 65: 552–8.

Five patients with refractory MMP were treated with rituximab. Complete remission occurred in three patients, partial remission in the other two. No serious side effects were noted.

Rituximab for patients with refractory mucous membrane pemphigoid

Le Roux-Villet C, Prost-Squarcioni C, Alexandre M, Caux F, Pascal F, Doan S, et al. Arch Dermatol 2011; 147: 843–9.

Twenty-five patients with severe refractory MMP received one or two cycles of rituximab; complete response occurred in 22 patients and partial response in 1. Two patients died from infectious

complications; these patients also received high-dose immunosuppression for laryngeal and tracheal edema.

One or two cycles of rituximab (375 mg/m² weekly for 4 weeks).

Twenty-one of the patients were receiving concomitant therapy with dapsone and/or sulfasalazine therapy, which was maintained during rituximab cycles.

Bullous and mucous membrane pemphigoid show a mixed response to rituximab: experience in seven patients

Lourari S, Doffoel-Hantz V, Meyer N, Bulai-Livideanu C, Viraben R, et al. *J Eur Acad Dermatol Venereol* 2011; 25: 1238–40.

Two patients with MMP were treated with rituximab, leading to complete remission in one and partial remission in the other. Four infusions of rituximab were given at weekly intervals at a dose of 375 mg/m².

Rituximab preserves vision in ocular mucous membrane pemphigoid

Rübsam A, Stefaniak R, Worm M, Pleyer U. *Expert Opin Biol Ther* 2015; 15: 927–33.

Retrospective case series of six patients treated with rituximab at high doses either as monotherapy (3/6) or with concomitant immunosuppression (3/6). Five patients had ocular disease, and one had extensive disease. After one cycle all achieved short-term complete remission. After a second cycle, 2/6 achieved complete remission and 3/6 partial remission. Mean follow-up was 22 months. Two patients experienced infusion reactions.

Rituximab combined with conventional therapy versus conventional therapy alone for the treatment of mucous membrane pemphigoid (MMP)

Maley A, Warren M, Haberman I, Swerlick R, Kharod-Dholakia B, Feldman R. *J Am Acad Dermatol* 2016; 74: 835–40.

Retrospective review of 49 patients comparing outcomes of 24 who received rituximab and 25 who received conventional immunosuppression. All patients in the rituximab group achieved disease control with a mean time to disease control of 10.2 months, compared with 10 (40%) of the patients in the conventional immunosuppression group, with a mean time to disease control of 37.7 months. Adverse events were seen in 33% of the rituximab group

compared with 48% of the conventional group. The two groups were not matched, nor were they randomized; rituximab dosing was not uniform.

Ten patients were initially treated with the lymphoma protocol for rituximab (four weekly infusions of 375 mg/m²), and 14 patients were initially treated with the rheumatoid arthritis protocol (two infusions of 1000 mg given 15 days apart). Eleven patients were treated with a single course of rituximab, whereas 13 required additional therapy. The mean total infusions of rituximab were 5.25 (range 2–16, SD 3.98).

Data from two larger and several small retrospective case series suggest benefit of rituximab; further evidence is needed.

Therapeutic effect of etanercept in anti-laminin 5 (laminin 332) mucous membrane pemphigoid

Schulz S, Deuster D, Schmidt E, Bonsmann G, Beissert S. Int J Dermatol 2011; 50: 1129–31.

Recalcitrant cicatricial pemphigoid treated with the anti-TNF-alpha agent etanercept

Kennedy JS, Devillez RL, Henning JS. J Drugs Dermatol 2010; 9: 68–70.

Treatment of ocular cicatricial pemphigoid with the tumour necrosis factor alpha antagonist etanercept

Prey S, Robert PY, Drouet M, Sparsa A, Roux C, Bonnetblanc JM, et al. Acta Dermatol Venereol 2007; 87: 74–5.

Successful treatment of mucous membrane pemphigoid with etanercept in 3 patients

Canizares MJ, Smith DI, Connors MS, Maverick KJ, Heffernan MP. Arch Dermatol 2006; 142: 1457–61.

Cicatricial pemphigoid and therapy with the TNF inhibitor etanercept

Labrecque PG, Null M. J Am Acad Dermatol 2004; 50: 48.

Treatment of recalcitrant cicatricial pemphigoid with the tumor necrosis factor alpha antagonist etanercept

Sacher C, Rubbert A, König C, Scharffetter-Kochanek K, Krieg T, Hunzelmann N. J Am Acad Dermatol 2002; 46: 113–5.

These case reports describe eight patients who responded to etanercept 50 mg/week subcutaneously, including five with ocular disease. Two patients maintained remission after cessation of the drug, and another relapsed.

Successful treatment of mucous membrane pemphigoid with infliximab

Heffernan MP, Bentley DD. Arch Dermatol 2006; 142: 1268–70.

Treatment comprised 5 mg/kg week 0, 2, and every 8 weeks IV.

Mucous membrane pemphigoid in a series of 7 children and a review of the literature with particular reference to prognostic features and treatment

Veysey EC, McHenry P, Powell J, Crone M, Harper JL, Allen J, et al. Eur J Pediatr Dermatol 2007; 17: 218–26.

Two cases with MMP benefited from infliximab; disease was ocular and oral in both and esophageal in one.

The biologics, particularly the anti-TNF agent etanercept, may have a role, but evidence is limited.

Pentoxifylline (anti-tumor necrosis factor drug): effective adjunctive therapy in the control of ocular cicatricial pemphigoid

El Darouti MA, Fakhry Khattab MA, Hegazy RA, Hafez DA, Gawdat HI. Eur J Ophthalmol 2011; 21: 529–37.

Randomized blinded study of 30 patients with ocular MMP treated with IV methylprednisolone and cyclophosphamide, either with or without adjuvant pentoxifylline (IV then oral).

Patients in both groups received pulsed steroid therapy (500 mg IV methylprednisolone daily for 5 days) with cyclophosphamide (500 mg in 2 L saline given on day 1 of the pulse steroid therapy).

Adjuvant IV pentoxifylline was given at a dose of 400 mg tds for the first 3 days to the treatment group. Both cycles were repeated weekly until cessation of progression. Then the cycles were spaced to be given with pulsed oral steroid (60 mg prednisolone for 2 consecutive days) administered between cycles for both groups, with the addition of daily oral pentoxifylline (400 mg) in the treatment group. This was repeated until the end of the study, for a total duration 6 months.

Inflammation and progression of scarring were reduced in patients receiving pentoxifylline.

Adjuvant pentoxifylline appears beneficial in control of ocular disease;

further evidence is needed.

Oral mucous membrane pemphigoid: complete response to topical tacrolimus

Lee HY, Blazek C, Beltraminelli H, Borradori L. Acta Derm Venereol 2011; 91: 604–5.

Single case of a complete response to oral suspension of tacrolimus 0.03% in aqueous solution, twice daily as an oral rinse.

Successful treatment of mucous membrane pemphigoid with tacrolimus

Suresh L, Martinex Caixto LE, Radfar L. Spec Care Dentist 2006; 26: 66–70.

Case report: patient treated with tacrolimus ointment. 0.1% tds for 6 weeks.

Single case reports suggest topical tacrolimus may be of benefit.

Low-level laser therapy for oral mucous membrane pemphigoid

Cafaro A, Broccoletti R, Arduino PG. Lasers Med Sci 2012; 27: 1247–50.

Laser light may improve the symptoms of oral lesions of cicatricial pemphigoid: a case report

Oliveira PC, Reis Junior JA, Lacerda JA, Silveira NT, Santos JM, Vitale MC, et al. Photomed Laser Surg 2009; 27: 825–8.

Laser phototherapy (GaAlAs diode laser, 660-nm wavelength, 30 mW, continuous wave, diameter approx. 3 mm, 60 J/cm² per session) was used in association with oral prednisolone (40 mg).

Low-level laser therapy in the treatment of mucous membrane pemphigoid: a promising procedure

Yilmaz HG, Kusakci-Seker B, Bayindir H, Tözüm TF. J Periodontol 2010; 81: 1226–30.

Single case report of patient treated with 810-nm diode laser. The lesions were treated by low-light laser therapy over a period of 7 days using a continuous waveform for 40 seconds and an energy density of 5 J/cm².

Five patients with oral disease have received treatment with low-level laser, either as an adjunct or alone, with benefit reported.

Mycetoma

Eumycetoma and actinomycetoma

Mahreen Ameen, and Wanda Sonia Robles

Mycetomas (Madura foot) are endemic in the tropics and subtropics. They are chronic, granulomatous, subcutaneous infections caused by either actinomycetes bacteria or eumycetes fungi, giving rising to actinomycetomas and eumycetomas, respectively. The infectious agents are saprophytes existing in soil or plants, and infection usually results from traumatic inoculation into the skin.

Consequently, the disease most commonly affects agriculturalists and those who are barefoot. The disease is characterized by abscesses, draining sinuses, and discharging grains, and it slowly progresses with risk of bone and visceral involvement. The discharging grains represent aggregates of fungal hyphae or bacterial filaments.

Actinomycetomas are produced by agents of the genera *Nocardia*, *Actinomadura*, *Streptomyces*, and *Nocardiosis*. *Nocardia* is the most common agent, particularly in the Americas, but *Streptomyces somaliensis* is more common in Sudan and the Middle East.

Eumycetomas are caused by a large number of fungi: *Madurella mycetomatis* is of particular significance as it is the most prevalent causative agent in regions of India and Africa.

Management Strategy

Treatment of mycetomas is generally difficult, and management varies from a very conservative approach to chemotherapy and surgery. Effective chemotherapy is available for actinomycetomas; however, eumycetomas are more refractory to drug therapy.

Eumycetomas may sometimes be managed conservatively as they are usually indolent and seldom life threatening. Treatment is then symptomatic with relief of pain and applications of dressings to affected areas, particularly the sinuses. Any secondary bacterial infection requires treatment. More active management consists of long courses of antifungals, 18 to 24 months or even longer, together with aggressive surgical excision and debulking. Antifungal therapy is initiated before surgery and continued afterward to reduce the risk of recurrence. Small lesions have a more favorable prognosis as they are more easily excised completely. Advanced disease with bony involvement characteristically shows poor therapy response and often requires surgical amputation. Of all the antifungal drugs, azoles have been most commonly used. Fluconazole has been found to be ineffective but ketoconazole and itraconazole have both demonstrated efficacy, particularly at high doses (200–400 mg daily for ketoconazole and 300–400 mg daily for itraconazole). Itraconazole is preferred as it is better tolerated for longer periods and is thought to demonstrate greater efficacy than ketoconazole, although there are no published studies comparing their efficacy. There are reports of the high tolerability and efficacy of the newer broad-spectrum triazoles, such as voriconazole and posaconazole, against *Madurella* species and

Scedosporium apiospermum infection. This is supported by in vitro susceptibility testing. However, their high costs are prohibitive for use in most endemic regions. Griseofulvin appears to be ineffective. Amphotericin has shown variable responses in the few cases in which it has been used. High-dose terbinafine (500 mg twice daily) has demonstrated limited clinical efficacy, which correlates with in vitro susceptibility testing, which has shown only moderate efficacy of terbinafine against some black-grain mycetomas. In vitro studies have not demonstrated any efficacy of echinocandins against *Madurella mycetomatis*.

Actinomycetomas are usually amenable to antibiotic therapy, but cure rates vary widely from 60% to 90%. Combined drug therapy is preferred in order to prevent the development of drug resistance, as well as to eradicate any residual infection. The duration of drug therapy depends on clinical response. Cure is defined by a lack of clinical activity, absence of grains, and negative cultures. Treatment with sulfonamides and sulfonamide combinations such as trimethoprim–sulfamethoxazole (cotrimoxazole) are usually first line. Aminoglycosides, tetracyclines, rifampicin, ciprofloxacin, and amoxicillin–clavulanate have also been successfully used. Parenteral amikacin and oral cotrimoxazole combination therapy is especially advocated for cases at risk of bone or visceral involvement. Actinomycetomas seldom require surgical management.

Specific Investigations

- Direct microscopy
- Culture
- Histopathology

It is imperative to differentiate between eumycetomas, which respond poorly to chemotherapy, and actinomycetomas, which generally respond well. Furthermore, species identification is important as it has treatment and prognostic implications—some species having demonstrated higher efficacy to some chemotherapy regimens than others.

The clinical diagnosis can be confirmed by the demonstration and identification of grains, which can be obtained by direct extraction, fine needle aspiration, or deep tissue biopsy. Direct microscopy of a crushed grain in 20% potassium hydroxide gives an indication of the

size and shape of the grain, which provides an initial clue to the causative agent, whether bacterial or fungal. Histopathology of a deep surgical biopsy demonstrates a granulomatous, inflammatory reaction with abscesses containing grains. Culture of grains using Sabouraud or blood agar media permits species identification. However, fungal culture can be particularly difficult, as morphologic differentiation of fungi may be poor or delayed. Molecular tests have therefore been developed for species identification of several black-grained eumycetoma, including species-specific polymerase chain reaction (PCR) analysis. Serologic tests such as enzyme-linked immunosorbent assay (ELISA) are employed by some centers to support diagnosis as well as to assess therapy response. Radiology and ultrasound enable assessment of disease extent and bony involvement. Helical computed tomography can provide detailed assessments of soft tissue and visceral involvement.

Hand mycetoma: The Mycetoma Research Centre experience and literature

Omer RF, Seif El Din N, Abdel Rahim FA, Fahal AH. PLoS Negl Trop Dis 2016; 10: e0004886.

Data is discussed on 533 patients with hand mycetoma managed over a period of 24 years at the Mycetoma Research Centre, Khartoum, Sudan. A reported 83.3% had eumycetoma, which were treated with ketoconazole (400–800 mg daily) or itraconazole (200–400 mg daily). Actinomycetomas were treated with streptomycin sulfate (1 gram daily), dapsone (100 mg daily), or streptomycin and trimethoprim–sulfamethoxazole (8/40 mg/kg/day), which was sometimes combined with amikacin (15 mg/kg/day) and given in cycles.

The surgical treatment of mycetoma

Suleiman SH, Wadaella el S, Fahal AH. PLoS Negl Trop Dis 2016; 10: e0004690.

The Mycetoma Research Centre, Khartoum, Sudan, has extensive experience in the surgical management of mycetomas and discusses different surgical options, including wide local excision, repetitive debridement, and amputation.

Mycetoma: a unique neglected tropical disease

Zijlstra EE, van de Sande WW, Welsh O, Mahgoub el S, Goodfellow

M, Fahal AH. Lancet Infect Dis 2016; 16: 100–12.

A comprehensive up-to-date review discussing current therapeutics and future challenges.

Mycetoma in the Sudan: an update from the Mycetoma Research Centre, University of Khartoum, Sudan

Fahal A, Mahgoub el S, El Hassan AM, Abdel-Rahman ME. PLoS Negl Trop Dis 2015; 9: e0003679.

This world-renowned center, which has seen the greatest number of mycetoma cases, describes their experience of 6792 patients seen during the period 1991 to 2014. *Madurella mycetomatis* eumycetoma was the most common type found in 70%.

Eumycetoma and actinomycetoma—an update on causative agents, epidemiology, pathogenesis, diagnostics and therapy

Nenoff P, van de Sande WW, Fahal AH, Reinel D, Schöfer H. J Eur Acad Dermatol Venereol 2015; 29: 1873–83.

This article covers both fungal and bacterial mycetomas and presents data on their treatment.

Mycetoma: experience of 482 cases in a single center in Mexico

Bonifaz A, Tirado-Sánchez A, Calderón L, Saúl A, Araiza J, Hernández M, et al. PLoS Negl Trop Dis 2014; 8: e3102.

This is a retrospective study reporting epidemiologic, clinical, and microbiologic data on all cases of mycetoma seen over a 33-year period (1980–2013) in Mexico City. Ninety-two percent of cases were actinomycetomas, and 78% of these were due to *Nocardia brasiliensis*.

Mycetoma medical therapy

Welsh O, Al-Abdely HM, Salinas-Carmona MC, Fahal AH. PLoS Negl Trop Dis 2014; 8: e3218.

Drug therapies for both actinomycetomas and eumycetomas are comprehensively covered.

First-Line Therapies

• Sulfonamides	B
• Aminoglycosides	B
• Itraconazole	C

Actinomycetomas in Senegal. Study of 90 cases

Dieng MT, Niang SO, Diop B, Ndiaye B. Bull Soc Pathol Exot Filiales 2005; 98: 18–20.

Ninety patients with actinomycetomas (*A. pelletieri*, *n* = 60; *A. madurae*, *n* = 25; *S. somaliensis*, *n* = 5) in Senegal were treated with sulfamethoxazole monotherapy. Despite bone involvement in 55% of cases, cure was achieved after 1 year of treatment in 83% of patients. Fifty percent of these cases were localized to the foot. Despite treatment two patients died of visceral involvement.

Mycetoma in children: experience with 15 cases

Bonifaz A, Ibarra G, Saul A, Paredes-Solis V, Carrasco-Gerard E, Fierro-Arias L. Pediatr Inf Dis J 2007; 26: 50–2.

Mycetomas are very rare in children, but the clinical presentation and course are similar to that in adults. There were 13 cases of *Nocardia* actinomycetoma and 2 cases of *M. mycetomatis* eumycetoma. Sulfonamide combinations were advocated as first-line therapy for actinomycetomas and amoxicillin–clavulanate as second-line therapy. Itraconazole and ketoconazole were used in the management of eumycetomas.

A modified two-step treatment for actinomycetoma

Ramam M, Bhat R, Garg T, Sharma VK, Ray R, Singh MK et al. Indian J Dermatol Venereol Leprol 2007; 73: 235–9.

The authors emphasize that although parenteral therapy regimens demonstrate high efficacy, they are costly in terms of inpatient stays. They describe a reduced parenteral regimen (intravenous gentamicin

80 mg twice daily together with oral cotrimoxazole 320–1600 mg twice daily for 1 month), followed by a longer phase of oral medication (doxycycline 100 mg twice daily together with cotrimoxazole at the same dose). All 21 patients demonstrated significant clinical response at the end of the parenteral phase of treatment. The oral phase needed to be continued for 3.5 to 16 months (mean 9.1 months) until cure, and in the majority of these patients this included a treatment period of 5 to 6 months after complete healing of the lesions to prevent any relapse.

Clinical and mycologic findings and therapeutic outcome of 27 mycetoma patients from São Paulo, Brazil

Castro LG, Piquero-Casals J. *Int J Dermatol* 2008; 47: 160–3.

This article describes the treatment of 13 cases of eumycetoma (with itraconazole) and 14 cases of actinomycetoma (with cotrimoxazole). Combination drug therapy was used in more than half of the cases. There was higher efficacy in three patients with actinomycetoma treated with cotrimoxazole in combination with amikacin. However, two of these patients developed hearing loss after treatment. The authors emphasize the problems of diagnostic testing, even in secondary and tertiary health centers, and were only able to identify the etiologic agent in fewer than half of their cases.

Improvement of eumycetoma with itraconazole

Smith EL, Kutbi S. *J Am Acad Dermatol* 1997; 34: 279–80.

This study from Saudi Arabia treated 25 patients with a follow-up period of 12 years. The authors recommend a combination itraconazole drug therapy together with surgical excision or debulking. Drainage of sinuses with removal of grains that can cause inflammation reduced pain and swelling.

Mycetoma in children

Fahal AH, Sabaa AH. *Trans R Soc Trop Med Hyg* 2010; 104: 117–21.

A large retrospective study of 722 children (age range 4–17 years) with confirmed mycetoma seen at the Mycetoma Research Centre, Sudan, during a 20-year period until 2009. Diagnosis was established by cytologic and ultrasound examinations of the lesions and histologic examination of the surgical biopsies. Most of the patients had eumycetomas. Combined medical treatment and surgical excision was the standard treatment. Disease recurrence after surgical excision

was reported in 17.9% of patients.

The safety and efficacy of itraconazole for the treatment of patients with eumycetoma due to *Madurella mycetomatis*

Fahal AH, Rahman IA, El-Hassan AM, Rahman ME, Zijlstra EE. Trans R Soc Trop Med Hyg 2011; 105: 127–32.

This prospective study of 13 patients demonstrated that preoperative treatment with a 1-year course of itraconazole enhances lesion encapsulation, which facilitates wide local excision, avoiding unnecessary mutilating surgery. Itraconazole was given at 400 mg daily for 3 months followed by a reduced dose of 200 mg daily for 9 months. All patients showed a good clinical response to the 400-mg daily dose but a slower response to the 200-mg daily dose. Posttreatment surgical exploration demonstrated that all lesions were well localized and encapsulated and easily removed. There was only a single recurrence after a follow-up period of 18 to 36 months.

Second-Line Therapies

• Amoxicillin–clavulanate	B
• Terbinafine	B
• Ketoconazole	C
• Posaconazole	D
• Imipenem	D
• Voriconazole	D
• Oxazolidinones	E

Last generation triazoles for imported eumycetoma in eleven consecutive adults

Crabol Y, Poiree S, Bougnoux ME, Maunoury C, Barete S, Zeller V et al. PLoS Negl Trop Dis 2014; 8: e3232.

Data is presented on 11 cases of eumycetoma (*Fusarium solani* complex $n = 3$; *Madurella mycetomatis* $n = 3$; *Exophiala jeanselmei* $n = 1$) that were treated by either voriconazole or posaconazole for a mean duration of 25.9 ± 18 months. There was complete response (major clinical and magnetic resonance imaging [MRI] improvement) in 5/11, partial response in 5/11, and failure in 1/11. Optimal outcome was associated with fungal species and initiation of drug therapy <65 months since first symptoms.

Treatment of actinomycetoma due to *Nocardia* spp. with amoxicillin-clavulanate

Bonifaz A, Flores P, Saul A, Carrasco-Gerard E, Ponce RM. Br J Dermatol 2007; 156: 308–11.

This study advocates amoxicillin–clavulanate as rescue therapy in patients with *Nocardia* spp. refractory to other therapy regimens. Twenty-one patients who had previously failed on other therapy regimens were treated with oral amoxicillin–clavulanate 875/125 mg twice daily. There was clinical and microbiologic cure in 15 (71%) patients after a mean treatment period of 10 months. Patients with bone and visceral involvement required longer treatment periods.

Clinical efficacy and safety of oral terbinafine in fungal mycetoma

N'Diaye B, Dieng MT, Perez A, Stockmeyer M, Bakshi R. Int J Dermatol 2006; 45: 154–7.

High-dose terbinafine, 500 mg twice daily, was given to 23 patients with eumycetomas in Senegal. After 24 to 48 weeks of treatment mycologic cure was seen in 25% patients, and a further 55% of patients demonstrated clinical improvement. Treatment was well tolerated.

This is the only study of terbinafine monotherapy for the treatment of eumycetomas, perhaps because the drug is prohibitively expensive in countries endemic for the infection.

Ketoconazole in the treatment of eumycetoma due to *Madurella mycetomii*

Mahgoub ES, Gumaa SA. Trans R Soc Trop Med Hyg 1984; 78: 376–9.

This trial consisted of 13 patients treated in the Sudan and Saudi Arabia. Ketoconazole was given at doses of 200 to 400 mg daily for 3 to 36 months (median 13 months). Treatment was well tolerated. Five patients were cured, and a further 4 improved. Response appeared to be dose dependent. The authors recommend a 400-mg daily dose of ketoconazole and a minimum treatment period of 12 months where there is bony involvement irrespective of clinical improvement.

Given the availability of newer antifungals, there are a few recent trials evaluating the use of ketoconazole for eumycetomas. However, it is a less expensive drug than itraconazole and therefore is more commonly used in endemic regions.

Posaconazole treatment of refractory eumycetoma and chromoblastomycosis

Negroni R, Tobon A, Bustamante B, Shikanai-Yasuda MA, Patino H, Restrepo A. Rev Inst Med Trop Sao Paulo 2005; 47: 339–46.

In this study from Argentina, posaconazole (800 mg daily in divided doses) was given to six patients with eumycetoma (*M. grisea*, $n = 3$; *M. mycetomatis*, $n = 2$; *S. apiospermum*, $n = 1$) resistant to standard therapy. There was partial and complete clinical response in five of the six patients. Treatment was well tolerated, even after long-term administration of more than 2 years.

Efficacy of imipenem therapy for *Nocardia* actinomycetomas refractory to sulphonamides

Ameen M, Arenas R, Vásquez del Mercado, Torres E, Zacarias R. J Am Acad Dermatol 2010; 62: 239–46.

Eight patients with severe and protracted infection (two with visceral and a further two with bone involvement) refractory to previous sulfonamide monotherapy received a 3-week course of parenteral imipenem (1.5 g daily, $n = 3$) given as either monotherapy or in combination with amikacin (1 g daily, $n = 5$). Treatment cycles were repeated at 6-month intervals. Oral cotrimoxazole was also given and continued between cycles. Treatment was well tolerated, and four patients achieved clinical and microbiologic cure after one to two cycles of treatment, with the others demonstrating greater than 75% clinical improvement and negative culture results.

This study also demonstrated that sulfonamides are effective for limited disease of relatively short duration. Their partial efficacy in severe cases was

the reason for continuing treatment with sulfonamides in combination with imipenem.

***Madurella mycetomatis* mycetoma treated successfully with oral voriconazole**

Lacroix C, De Kerviller E, Morel P, Derouin F, Feuilhade de Chavin M. Br J Dermatol 2005; 152: 1067–8.

Voriconazole has been reported to be effective in the management of disseminated fungal infections with *Scedosporium* and *Fusarium* spp. This is the first report of successful treatment of a eumycetoma with oral voriconazole monotherapy given for 16 months at a dose of 300 mg twice daily. The treatment was well tolerated, and the patient remained disease free 4 years after the end of treatment.

***Scedosporium apiospermum* mycetoma with bone involvement successfully treated with voriconazole**

Porte L, Khatibi S, Hajj LE, Cassaing S, Berry A, Massip P, et al. Trans R Soc Trop Med Hyg 2006; 100: 891–4.

Scedosporium apiospermum mycetoma usually requires limb amputation. This case with bone involvement that had previously failed with itraconazole, fluconazole, and cotrimoxazole was given voriconazole 400 mg daily for 18 months. There was a good clinical response, and MRI demonstrated impressive regression of bony lesions. Treatment, however, was discontinued because of hepatic impairment.

This report suggests voriconazole as a promising treatment option for S. apiospermum mycetomas.

Clinical experience with linezolid for the treatment of *Nocardia* infection

Moylett EH, Pacheco SE, Brown-Elliott BA, Perry TR, Buescher ES, Birmingham MC. Clin Infect Dis 2003; 36: 313–8.

Oral linezolid belongs to the new broad-spectrum oxazolidinones. This report describes its successful use in *Nocardia* infection. There was only a single case of cutaneous infection with *N. brasiliensis*. Linezolid produced clinical cure after only 2 months of treatment at a dose of 600 mg twice daily.

Third-Line Therapies

• Rifampicin	C
• Amphotericin B	D

Modified Welsh regimen: a promising therapy for actinomycetoma

Damle DK, Mahajan PM, Pradhan SN, Belgaumkar VA, Gosavi AP, Tolat SN, et al. J Drugs Dermatol 2008; 7: 853–6.

Eighteen patients with poor responses to previous therapies were treated with the standard “Welsh regimen” consisting of amikacin and cotrimoxazole in combination with rifampicin. Sixteen patients who completed treatment were cured and remained in remission during a follow-up period of up to 18 months.

This study has demonstrated efficacy and tolerability of these three drugs in combination. There are also reported cases of rifampicin being added to sulfonamides to improve efficacy.

***Scedosporium* infection in immunocompromised patients: successful use of liposomal amphotericin B and itraconazole**

Barbaric D, Shaw PJ. Med Pediatr Oncol 2001; 37: 122–5.

A report of five cases of *Scedosporium* infection in immunosuppressed patients. Three of these patients died despite treatment with various combinations of amphotericin B and itraconazole. Two patients were successfully treated with liposomal amphotericin B and itraconazole.

Mycobacterial (atypical) skin infections

Ure Eke, and John Berth-Jones

Atypical, or “nontuberculous” mycobacterial infections are being increasingly recognized and reported. Over 150 species in this genus are now recognized and are broadly divided into slow-growing and rapidly growing mycobacteria. Most outbreaks of infection arise from various sources of contaminated water, in a diverse range of

domestic, occupational, clinical, and environmental settings. Cutaneous infection is often opportunistic, after preexisting trauma or inflammation of the skin, and nosocomial infections have been associated with a range of cosmetic and surgical procedures. Mycobacteria exhibit high levels of resistance to disinfectants and antiseptics, and have often been isolated from sources that may be considered “clean,” such as chlorinated tap water.

Specific Investigations

- Histology
- Tissue culture
- Polymerase chain reaction (PCR)

Although some classical presentations are diagnosed clinically, mycobacterial infection is often unexpected, so a high level of awareness of these infections may be required. Histology is often helpful, and culture enables antimicrobial sensitivity to be investigated. Definitive diagnosis is achieved by PCR and related methodologies, and precise identification of the species involved will often assist with treatment.

Fish Tank (Swimming Pool) Granuloma

Fish tank granuloma is an infection of the skin caused by *Mycobacterium marinum*, presenting with plaques and nodules, commonly on the upper extremities, which may spread in a sporotrichoid fashion after an incubation period of 2 to 6 weeks. The most common sources of infection are tropical fish aquariums and swimming pools. The infection is commonly limited to the skin, but tenosynovitis, osteomyelitis, and arthritis have been reported with deeper infections. Rarely, disseminated infection may occur, especially in the immunocompromised. There are reports of the development of cutaneous *M. marinum* infection during treatment with infliximab and adalimumab, although paradoxically, infliximab has been found to be a useful adjunctive therapy in the management of *M. marinum* infection.

Management Strategy

Diagnosis is often suspected from the history and clinical features. Histology shows noncaseating granulomas, but a complete absence of epithelioid cells and multinucleate giant cells is not unusual in acute lesions. Suppurative, tuberculoid, and palisading patterns of granulomas have been described. Dermal small vessel proliferation with mixed inflammation may be a good indicator of cutaneous atypical mycobacterial infections. Ziehl–Nielsen staining is positive for acid-fast bacilli in 30% of biopsies. Culture of the biopsy specimen at 30 to 33°C yields pigmented colonies of *M. marinum*. In vitro sensitivity studies have not been uniformly predictive of clinical response to the antibiotics. They do not have a routine role in directing initial treatment but may be useful in resistant cases. PCR is rapid and sensitive and can be performed on formalin-fixed, paraffin-embedded specimens.

Spontaneous resolution may occur within 3 years, but treatment is recommended for rapid recovery and prevention of dissemination. Although controlled trials are lacking, successful treatment is reported with various *antibiotics* given singly or in combination. The mean duration of treatment in various reports ranges from 6 to 20 weeks. No statistical difference in efficacy between treatments has been demonstrated. Lesions can often be effectively treated by *simple excision*, but occasionally this seems to result in a prolonged infection. The second-line treatments described later have been so designated as there is less published experience with them. The third-line treatments (e.g., *heat treatment*) are probably best regarded as adjunctive.

First-Line Therapies

• Minocycline 100–200 mg once daily for 6–12 weeks	C
• Doxycycline 100 mg twice daily for 3–4 months	C
• Clarithromycin 500 mg once or twice daily for 3–4 months	C
• Rifampicin 600 mg and ethambutol 1.2 g daily for 3–6 months	D
• Co-trimoxazole 2–3 tablets twice daily for 6 weeks	D
• Clarithromycin 250 mg twice daily and ethambutol 800 mg once daily for 2–6 months	D

Epidemiologic, clinical, and therapeutic pattern of *Mycobacterium marinum* infection: a retrospective series of 35 cases from southern France

Eberst E, Dereure O, Guillot B, Trento C, Terru D, van de Perre P, et al. J Am Acad Dermatol 2012; 66: e15–6.

Thirty-four of 35 (97%) had complete clearance of skin lesions with one course of oral antimicrobial therapy given over a period of 4 to 24 weeks (median 12.4 weeks). Single antibiotic therapy was successful in 25 patients. Fourteen of these received minocycline 200 mg daily, 5 patients received doxycycline 200 mg daily, and 6 clarithromycin 500 mg daily. Nine patients had dual antibiotic therapy using a combination of clarithromycin with doxycycline, minocycline, rifampicin, or ofloxacin.

Sixty-three cases of *Mycobacterium marinum* infection. Clinical features, treatment and antibiotic susceptibility of causative isolates

Aubry A, Chosidow O, Caumes E, Robert J, Cambau E. Arch Intern Med 2002; 162: 1746–5.

All patients were treated with antibiotics and 48% underwent surgery. Clarithromycin, doxycycline, and rifampicin were the most commonly prescribed antibiotics. Forty patients had drug combinations, commonly clarithromycin and rifampicin or tetracyclines, tetracyclines and rifampicin or ethambutol.

Soft tissue infections caused by marine bacterial pathogens: epidemiology, diagnosis, and management

Finkelstein R, Oren I. Curr Infect Dis Rep 2011; 13: 470–7.

The authors support the use of dual antibiotic therapy to reduce the risk of resistance while advocating monotherapy for limited superficial infection. Suggested recommended treatment regimens include rifampicin with ethambutol, clarithromycin with ethambutol, clarithromycin with minocycline, and clarithromycin or minocycline monotherapy. They suggest that antibiotics should be given for 3 or 4 months and treatment should be continued for 1 to 2 months after resolution of lesions to reduce the chance of relapse.

Atypical mycobacterial cutaneous infections in Hong Kong: 10 year retrospective study

Ho MH, Ho CK, Chong LY. Hong Kong Med J 2006; 12: 21–6.

Seventeen cases of *M. marinum* were identified over a 10-year period. Thirteen responded to treatment with oral tetracycline alone (9 minocycline and 4 doxycycline). Two patients had antituberculous drugs initially but were subsequently switched to minocycline. One patient had a combination of isoniazid, rifampicin, ethambutol, and minocycline. The average duration of treatment was 20 weeks. The authors recommend minocycline 100 mg twice daily as the treatment of choice.

Cutaneous non-tuberculous mycobacterial infections: a clinical and histopathological study of 17 cases from Lebanon

Abbas O, Marrouch N, Kattar MM, Zeynoun S, Kibbi AG, Rached RA, et al. J Eur Acad Dermatol Venereol 2011; 25: 33–42.

Ten out of 11 patients were successfully treated with either minocycline 100 mg twice a day (6 patients) or clarithromycin 500 mg twice a day monotherapy (4 patients). Patients were treated for an average of 4.8 months (range 3–8 months).

Second-Line Therapies

• Ciprofloxacin 500 mg + clarithromycin 250 mg twice daily for 4 months	E
• Rifabutin 600 mg + clarithromycin 500 mg twice daily + ciprofloxacin 500 mg twice daily for 4 months	E
• Azithromycin 500 mg three times a week for 2 months	E
• Lymecycline 150 mg daily for 55 days	E
• Rifampicin 450 mg daily, clarithromycin 500 mg twice daily, amikacin 400 mg intravenously once daily for 6 months	E

Successful treatment of refractory cutaneous infection caused by *Mycobacterium marinum* with a combined regimen containing amikacin

Huang Y, Xu X, Liu Y, Wu K, Zhang W, Liu P, et al. Clin Interv Aging 2012; 7: 533–8.

A rapidly progressive infection failing to respond to rifampicin, clarithromycin, and moxifloxacin settled promptly when the listed regimen containing amikacin.

Third-Line Therapies

• Simple excision	E
• Curettage and electrodesiccation	E
• Incision and drainage	E
• Heat therapy by gloves, hot water, or heated armlet	E
• Photodynamic therapy	E
• Cryotherapy	E
• Adjunctive anti-TNF- α inhibitors	E

Treatment of *Mycobacterium marinum* cutaneous infections

Rallis E, Koumantaki-Mathioudaki E. Expert Opin Pharmacother 2007; 8: 2965–78.

Review article. Surgical treatment may not be necessary or may even be contraindicated in some patients and should be reserved for cases with isolated superficial lesions that are nonresponsive to systemic therapy. Cryotherapy, electrodesiccation, photodynamic therapy, and local hyperthermic therapy have also been reported with some success.

Efficacy of oral minocycline and hyperthermic treatment in a case of atypical mycobacterial skin infection by *Mycobacterium marinum*

Hisamichi K, Hiruma M, Yamazaki M, Matsushita A, Ogawa H. J Dermatol 2002; 29: 810–1.

Minocycline 200 mg daily and local hyperthermic treatment (a disposable chemical pocket warmer) was used every evening for 5 to 6 hours over 2.5 months. Although there have been four cases in Japan where patients have been treated with hyperthermic treatment alone, the authors advocate it to be used in conjunction with minocycline.

***Mycobacterium marinum* infection cured by photodynamic therapy**

Wiegell SR, Kongshoj B, Wulf HC. Arch Dermatol 2006; 142: 1241–2.

A patient intolerant of antibiotics was cured by treatment with

methyl aminolevulinate applied for 3 hours, followed by illumination with 37 J/cm² of red light, undertaken once weekly for 3 weeks.

Possible role of anti-TNF monoclonal antibodies in the treatment of *Mycobacterium marinum* infection

Garzoni C, Adler S, Boller C, Furrer H, Villiger PM. Rheumatology 2010; 49: 1991–3.

A patient with PCR-confirmed *M. marinum* synovial infection of the foot was given triple combination therapy of ethambutol, clarithromycin, and rifampicin for 4 months. Clinical improvement was noted with the subsequent addition of infliximab 5 mg/kg/month.

***Mycobacterium marinum* infection of the hand and wrist**

Cheung JP, Fung B, Wong SS, Ip WY. J Orthop Surg 2010; 18: 98–103.

In this review article the authors support the use of combination therapy with rifampicin, ethambutol, and clarithromycin for *M. marinum* infection of the hand and wrist, which may be complicated by tenosynovitis leading to joint immobilization and contractures. They advocate surgical debridement for deep-seated infections.

Mycobacterium ulcerans

Mycobacterium ulcerans (Buruli ulcer) is the third most common mycobacterial infection, after leprosy and tuberculosis, in immunocompetent hosts. It occurs most commonly in wetlands of tropical and subtropical countries (Africa and Australia). Children under 15 years of age are most commonly affected. After inoculation into the skin, *M. ulcerans* proliferates and produces a toxin, mycolactone, which enters the cells and causes necrosis of the dermis, panniculus, and deep fascia. Initially firm, painless nodules, papules, or plaques are seen. As the necrosis spreads, overlying ulceration develops over 1 or 2 months. The ulcers have a characteristic undermined edge and necrotic base. Although indolent in the majority, the ulcers can grow rapidly to more than 15 cm, with resultant extensive scarring and deformity. Up to 13% of patients may develop systemic involvement.

Management Strategy

There are anecdotal reports of spontaneous resolution of cutaneous *M. ulcerans* infection, but early treatment is recommended to limit disease progression and prevent contractures. The World Health Organization recommends *combination chemotherapy* with oral rifampicin and intramuscular streptomycin as first-line treatment. Adjunctive *surgical excision* may be required for necrotic or unhealed skin tissue. Antimicrobial therapy may reduce the extent of surgical excision. Recent combined therapy options contain oral preparations, which are easier to administer and show similar efficacy. There can be paradoxical clinical deterioration peaking around week 8 of antimicrobial therapy before subsequent improvement. This response does not indicate treatment failure and may be the result of temporary immunostimulation from antimicrobial treatment. Adequate wound care and the use of bed nets offer protection against *M. ulcerans* infections in endemic areas. Independent risk factors for relapse after surgery alone include incomplete excision, age under 16 years, leg edema, and plaque-like lesions before ulceration.

Smears from the necrotic base of ulcers often reveal clumps of acid-fast bacilli on Ziehl–Nielsen staining. Appropriately selected biopsy specimens that include the necrotic base and the undermined edge of lesions with subcutaneous tissue are nearly always diagnostic. Histology reveals necrosis of the deep dermis and panniculitis. Inflammatory cells are few, presumably due to the immunosuppressive activity of the toxin. With healing, there is a granulomatous response, and the ulcerated area is eventually replaced by a depressed scar, which may result in functional disability. *M. ulcerans* can be cultured from exudates or tissue fragments, but visible growth often requires 6 to 8 weeks, incubation at 33°C. PCR is quicker and has the highest sensitivity compared with microscopy, culture, and histopathology. For PCR, a 3-mm punch biopsy is the best sample for nonulcerative lesions, whereas a swab is best for ulcerative lesions.

Screening of all cases for coinfection with HIV is recommended in locations where the latter is endemic.

First-Line Therapies

• Oral rifampicin daily at 10 mg/kg and streptomycin intramuscularly at 15 mg/kg daily for 8 weeks	B
• Rifampicin 10 mg/kg daily and clarithromycin 7.5 mg/kg twice daily for 8 weeks	B
• Rifampicin 10 mg/kg/day and moxifloxacin 400 mg once daily for 8 weeks (for adults)	C
• Adjunctive surgery with antibiotics	B
• Wide surgical excision alone	B
• Local heat (40°C)	C

Treatment of *Mycobacterium ulcerans* disease (Buruli ulcer); guidance for health workers

World Health Organization, Switzerland, Geneva 2012.

<http://onlinelibrary.wiley.com/doi/10.1111/tmi.12342/full#tmi12342-bib-0040>.

A nice review including advice on treatment. Rifampicin and streptomycin is recommended as standard treatment using the regimen noted earlier (although contraindicated in pregnancy). In Australia and French Guiana rifampicin is used with clarithromycin or moxifloxacin previously mentioned.

Antimicrobial treatment for early, limited *Mycobacterium ulcerans* infection: a randomised controlled trial

Nienhuis WA, Stienstra Y, Thompson WA, Awuah PC, Abass KM, Tuah W, et al. Lancet 2010; 375: 664–72.

In this open-label, randomized, multicenter trial, early lesions of *M. ulcerans* were treated with oral rifampicin 10 mg/kg/day and intramuscular streptomycin 15 mg/kg/day alone for 8 weeks or rifampicin and streptomycin for 4 weeks followed by oral rifampicin and clarithromycin 7.5 mg/kg/day for 4 weeks. Seventy-three patients (96%) in the former group and 68 (91%) in the latter had complete healing at 1 year with no recurrences. The authors recommend switching to oral clarithromycin at week 4 to limit the number of injections with streptomycin.

Clinical efficacy of combination of rifampin and streptomycin for treatment of *Mycobacterium ulcerans* disease

Sarfo FS, Phillips R, Asiedu K, Ampadu E, Bobi N, Adentwe E, et al. Antimicrob Agents Chemother 2010; 54: 3678–85.

A study of 160 patients with confirmed *M. ulcerans* infection treated with oral rifampicin 10 mg/kg/day and intramuscular streptomycin 15 mg/kg daily for 8 weeks. Ninety-five percent (152 patients) with early

and late forms of disease responded to therapy without surgery. In eight cases, surgical excision followed by split-skin graft repair was carried out at week 8 due to progressive lesions or nonhealing lesions. Complete healing was achieved between 2 and 48 weeks. There were no recurrences in 158 (98%) of cases. Treatment was generally well tolerated. Two patients changed from streptomycin to oral moxifloxacin 400 mg daily due to nausea, vomiting, and dizziness.

Successful outcomes with oral fluoroquinolones combined with rifampicin in the treatment of *Mycobacterium ulcerans*: an observational cohort study

O'Brien DP, McDonald A, Callan P, Robson M, Friedman ND, Hughes A, et al. PLoS Negl Trop Dis 2012; 6: e1473.

A prospective study of 147 cases: 47 had surgery alone with 30% treatment failure, 90 had combined surgical and medical treatment with no treatment failure. In the latter group, rifampicin and ciprofloxacin were used in 61% of patients and rifampicin and clarithromycin in 23% of cases. There was no evident difference in clinical efficacy between antibiotic regimens. Paradoxical reactions were seen in eight (9%) of the antibiotic-treated cases.

Effect of a control project on clinical profiles and outcomes in Buruli ulcer: a before/after study in Bas-Congo, Democratic Republic of Congo

Phanzy DM, Suykerbuyk P, Imposo DB, Lukanu PN, Minuku JB, Lehman LF, et al. PLoS Negl Trop Dis 2011; 5: e1402.

A prospective observational study in Congo comparing clinical outcomes of patients admitted with *M. ulcerans* ulcers. Between 2004 and 2007, 64 patients were treated with surgery alone resulting in healing in 48 patients; 15 patients were left with disability; 12 patients died due to sepsis. Between 2005 and 2007, 107/190 patients were treated with rifampicin and streptomycin. The majority of these patients were also treated with surgery. In this group, healing occurred in 176 of 190 patients, 37 were left with functional disability, and death occurred in 6 patients. Sepsis, malnutrition and anemia, and postsurgical shock were reported causes of fatality.

Histopathological changes and clinical responses of Buruli ulcer plaque lesions during chemotherapy: a role for surgical removal of necrotic tissue?

Ruf MT, Sopoh GE, Brun LV, Dossou AD, Barogui YT, Johnson RC, et al. PLoS Negl Trop Dis 2011; 5: e1334.

Of the 12 patients in the study, 9 were treated with limited surgical excision of necrotic tissues followed by skin grafting between 7 and 39 days after antimicrobial therapy. Surgical excision was not required in 3 of the 12 patients.

Pretreatment with antibiotics limits the extent of surgical excision required and thereby reduces post-treatment morbidity.

Phase change material for thermotherapy of Buruli ulcer: a prospective observational single center proof-of-principle trial

Junghanss T, Um Boock A, Vogel M, Schuette D, Weinlaeder H, Pluschke G. PLoS Negl Trop Dis 2009; 3: e380.

In this series, six patients with confirmed ulcerative Buruli lesions received thermotherapy for 28 to 31 days in lesions less than 2 cm (three patients) and 50 to 55 days in lesions equal to or larger than 2 cm (three patients). All had good outcomes with no recurrences 18 months after therapy.

Mycobacterium Kansasii

This organism most commonly causes pulmonary disease; skin lesions are rare. Most reported cases have occurred in immunocompromised subjects. The gross morphology of such lesions varies greatly and can be verrucous, nodular, pustular, ulcerated, or sporotrichoid. Cutaneous lesions may progress slowly or run an acute course.

Management Strategy

Although conventional combination chemotherapy with *antituberculous drugs* is effective, the choice of treatment should be determined by in vitro sensitivity. Resolution of *M. kansasii* infection has been reported after antiretroviral medication for HIV.

Lesions caused by *M. kansasii* may yield a variety of histopathologic features. They may be granulomatous in the chronic form or show necrosis with an intense inflammatory infiltrate composed of polymorphonuclear cells in the more acute form. The organisms grow best on Lowenstein–Jensen culture medium at 37°C.

First-Line Therapies

• Combination of antituberculous drugs for 6–18 months	D
• Antituberculous drugs with intramuscular kanamycin 500 mg three times a week for 3 months	E
• Minocycline 100–200 mg daily for 16 weeks	E
• Erythromycin 2 g daily for 6 months	E

Current treatment of nontuberculous mycobacteriosis: an update

Esteban J, García-Pedrazuela M, Muñoz-Egea MC, Alcaide F. Expert Opin Pharmacother 2012; 13: 967–86.

In this review the authors recommend isoniazid, rifampicin, and ethambutol for 18 months with at least 12 months of negative cultures. They conclude that there is a 6.9% risk of relapse with a 12-month multidrug regimen. In cases of resistance or adverse reactions, they recommend a 3-month course of streptomycin or amikacin followed by intermittent therapy with one of these drugs. Alternative treatments include clarithromycin, levofloxacin and moxifloxacin, and linezolid.

Mycobacterium kansasii infection presenting as cellulitis in a patient with systemic lupus erythematosus

Hsu PY, Yang YH, Hsiao CH, Lee PI, Chiang BL. Formos Med Assoc 2002; 101: 581–4.

In this case report the authors describe successful treatment of *M. kansasii* infection with rifampicin 600 mg daily, clarithromycin 500 mg twice a day, isoniazid 300 mg daily, and ethambutol 1200 mg daily for total of 1 year in a patient with known systemic lupus erythematosus (SLE).

Primary cutaneous *Mycobacterium kansasii* infection in a child

Chaves A, Torrelo A, Mediero IG, Menéndez-Rivas M, Ortega-Calderón A, Zambrano A. J Pediatr Dermatol 2001; 18: 131–4.

A case of *M. kansasii* infection in the elbow of an immunocompetent 6-year-old girl treated successfully with surgical excision and a 5-month course of erythromycin 50 mg/kg/day.

Rapidly Growing Mycobacteria

Mycobacterium fortuitum, *Mycobacterium chelonae*, and *Mycobacterium abscessus* are environmental pathogens also known as *rapidly growing mycobacteria* (RGM), so termed because colonies are visible to the naked eye within 7 days of culture. Cutaneous lesions due to these pathogens usually occur after surgery, percutaneous catheter insertion, or accidental inoculation. Dark red nodules develop, with abscess formation and clear fluid drainage. Disseminated disease occurs most commonly in immunosuppressed hosts.

Management Strategy

RGM should be individually identified and in vitro sensitivity tests performed before treatment. *M. fortuitum* and *M. chelonae* are resistant to most antituberculous drugs except kanamycin and amikacin. *M. fortuitum* may also be susceptible to cefoxitin, ciprofloxacin, and imipenem. *M. abscessus* is usually sensitive to amikacin, cefoxitin, and clarithromycin. Tobramycin and clarithromycin are more effective than amikacin in the treatment of *M. chelonae*. The wide variability in antibiotic sensitivity means that each case must be considered individually. For persistent nonhealing cutaneous lesions, wide excisional surgery with delayed closure or skin grafting can be undertaken. The duration of therapy can vary from 6 weeks to 7 months and is dictated by clinical and microbiological response.

Histology reveals polymorphonuclear microabscess and granuloma formation with foreign body-type giant cells. Acid-fast bacilli may be demonstrated in the microabscesses. Diagnosis is usually confirmed by culture. PCR systems can also be used for diagnosis and species identification in selected cases.

First-Line Therapies

Mycobacterium chelonae

• Clarithromycin 500 mg twice a day for 3–8 months ± surgery	C
• Azithromycin 250 mg daily for at least 6 months	E
• Clarithromycin as part of dual or triple therapy with ciprofloxacin, tobramycin, and tigecycline	E

Systematic review of tattoo-associated skin infection with rapidly

growing mycobacteria and public health investigation of a cluster in Scotland 2010

Conaglen PD, Laurenson IF, Sergeant A, Thorn SN, Rayner A, Stevenson J. Euro Surveill 2013; 18: 20553.

This article summarizes 25 previous reports (142 cases), from 11 countries, published between 2003 and 2012, of RGM infection associated with tattoos. Causative agents included *M. chelonae* (most frequently), *M. abscessus*, and *M. fortuitum*, among others. Spontaneous resolution was documented in several cases; others generally responded to a diverse range of antibiotics, including macrolides and tetracyclines, used alone or in combination, with surgery being required for nine cases in one report.

Clinical management of rapidly growing mycobacterial cutaneous infections in patients after mesotherapy

Regnier S, Cambau E, Meningaud JP, Guihot A, Deforges L, Carbonne A, et al. Clin Infect Dis 2009; 49: 1358–64.

Sixteen patients were diagnosed with cutaneous infection due to RGM after an outbreak after mesotherapy in France. *M. chelonae* was identified in 11 patients and *M. frederiksbergense* in 2 patients. Patients were treated with drug regimens containing clarithromycin. Six received triple therapy initially, and 8 received dual therapy. Fourteen received clarithromycin 1 to 2 g/day, 6 received intravenous tobramycin 3 mg/kg/day, 14 received ciprofloxacin 500 mg twice a day, and 6 received intravenous tigecycline initially at 100 mg followed by 50 mg/day. Patients were treated for a mean duration of 14 weeks (range 1–24 weeks), with time to healing estimated at 6.2 months (range 1–15 months). Success was noted in all but one patient.

First-Line Therapies

Mycobacterium fortuitum

• Clarithromycin 500 mg twice a day and levofloxacin 500 mg twice a day for 3–6 months	B
• Clarithromycin 250–500 mg twice a day ± intramuscular amikacin 250 mg three times a week for 3–6 months	C
• Ciprofloxacin 500 mg twice a day for 3–6 months	C
• Ciprofloxacin 500 mg twice a day, clarithromycin 500 mg twice a day, and amoxicillin–clavulanic acid 500 mg twice a day for 6 weeks	E
• Co-trimoxazole 800/160 mg twice a day, clarithromycin 500 mg twice a day, and amoxicillin–clavulanic acid 500 mg twice a day for 6 weeks	E
• Levofloxacin 300 mg daily	E
• Trimethoprim	D

An outbreak of *Mycobacterium fortuitum* cutaneous infection associated with mesotherapy

Quiñones C, Ramalle-Gómara E, Perucha M, Lezaun ME, Fernández-Vilariño E, García-Morrás P, et al. J Eur Acad Dermatol Venereol 2010; 24: 604–6.

Thirty-nine patients were suspected of having cutaneous *M. fortuitum* infection after mesotherapy in a beauty clinic. Twelve had culture-confirmed *M. fortuitum*. All were successfully treated with clarithromycin 500 mg twice a day and levofloxacin 500 mg daily for 3 to 6 months. Two underwent excision of localized lesions.

Cutaneous infection with *Mycobacterium fortuitum* after localized microinjections (mesotherapy) treated successfully with a triple drug regimen

Nagore E, Ramos P, Botella-Estrada R, Ramos-Níguez JA, Sanmartín O, Castejón P. Acta Derm Venereol 2001; 81: 291–3.

One case received a combination of ciprofloxacin 500 mg twice a day, clarithromycin 500 mg twice a day, and amoxicillin–clavulanic acid 500 mg twice a day for 6 weeks. One received treatment with clarithromycin, cotrimoxazole 800/160 mg twice a day, and amoxicillin–clavulanic acid. The third was given ciprofloxacin 500 mg twice a day, clarithromycin 500 mg twice a day, and co-trimoxazole 800/160 mg twice a day for 3 weeks followed by clarithromycin 500 mg twice a day. All lesions healed within 2 to 6 weeks.

Successful treatment of a widespread cutaneous *Mycobacterium fortuitum* infection with levofloxacin

Nakagawa K, Tsuruta D, Ishii M. Int J Dermatol 2006; 45: 1098–9.

An immunocompromised patient treated successfully with levofloxacin 300 mg daily. Duration not specified.

First-Line Therapies

Mycobacterium abscessus

• Clarithromycin 1 g/day for adults and 0.5 g/day for children for 3–6 months + adjunctive surgery	B
• Clarithromycin 250 mg twice a day + moxifloxacin 400 mg daily for 4–5 months	B
• Clarithromycin 250–500 mg twice a day ± intramuscular amikacin 250 mg three times a week for 3–6 months	B
• Multiple antibiotic therapy + adjunctive interferon-γ for refractory lesions	E

Report on an outbreak of postinjection abscesses due to *Mycobacterium abscessus*, including management with surgery and clarithromycin therapy and comparison of strains by random amplified polymorphic DNA polymerase chain reaction

Villanueva A, Calderon RV, Vargas BA, Ruiz F, Agüero S, Zhang Y, et al. Clin Infect Dis 1997; 24: 1147–53.

A cohort of 350 patients was clinically diagnosed with *M. abscessus* infections after an outbreak in a physician's office in Columbia (205 cases culture confirmed). Patients received either surgery alone or clarithromycin alone or combination of drugs and surgery. Of 35 patients treated with clarithromycin alone, 8 patients were cured (23%). Of 22 patients treated with surgical resection alone, 7 were cured (32%). Of 148 patients treated with combined surgery and clarithromycin, 140 were cured (95%). Clarithromycin was given at a dose of 1 g/day in adults and 0.5 g/day in children for 3 to 6 months.

Clarithromycin and amikacin vs. clarithromycin and moxifloxacin for the treatment of postacupuncture cutaneous infections due to *Mycobacterium abscessus*: a prospective observational study

Choi WS, Kim MJ, Park DW, Son SW, Yoon YK, Song T, et al. Clin Microbiol Infect 2011; 17: 1084–90.

A series of 52 patients with *M. abscessus* infection after acupuncture. Thirty-three were treated with oral clarithromycin 250 mg twice a day plus intramuscular amikacin 250 mg three times a week, and 19 were treated with oral clarithromycin 250 mg twice a day plus oral moxifloxacin 400 mg daily. The median time to resolution of lesions in the clarithromycin plus moxifloxacin-treated group was significantly shorter (17 vs. 20 weeks, respectively, $p = 0.017$).

Treatment of refractory disseminated *Mycobacterium abscessus* infection with interferon gamma therapy

Colsky AS, Hanly A, Elgart Kerdel FA. Arch Dermatol 1999; 135: 125–7.

Successful treatment of *M. abscessus* infection not responding to combination antibiotic therapy with kanamycin, cefotaxime, and clarithromycin given for 3 months, after adjunctive interferon- γ 50 $\mu\text{g}/\text{m}^2$ subcutaneously three times a week for 7 months.

Mycosis fungoides and Sézary syndrome

Pierluigi Porcu, and Henry K. Wong

Mycosis fungoides (MF) and Sézary syndrome (SS) are the most common subtypes of cutaneous T-cell lymphoma (CTCL), a heterogeneous group of extranodal non-Hodgkin lymphomas (NHLs) of the skin that includes the CD30-positive lymphoproliferative disorders. The identity of the T-cell subset and the specific immune compartment (blood, skin, or lymph nodes) initially targeted by the transforming event in CTCL are not known. The tumor cell in MF is a

mature, CD45RO+, CD4+, CLA+, skin-homing, effector memory T-cell lacking CCR7. In Sézary syndrome, the phenotype is a mature CD4+ T cell with the CCR7 central memory variant. Functional studies of T cells from patient samples have provided valuable insight into the pathogenesis and clinical aspects of MF. Decreased production of cytokines such as interferon (IFN) and IL-12, upregulation of inhibitory molecules such as CTLA-4 and PD1, and a diminished T-cell immune repertoire contribute to an increased risk of infections and of secondary malignancies. Highly selective skin trafficking, mediated by the chemokine receptors CCR4 and CCR10, target the skin across all stages of MF, even though tumor cells can be detected with highly sensitive methods in the blood and the lymph nodes. Finally, in the advanced stage of MF and SS, the presence of extensive gene mutations, complex chromosomal abnormalities, aberrant gene expression, unresponsiveness to growth-inhibitory signals, and defective apoptosis can drive the transformation into a highly aggressive and lethal malignancy.

MF accounts for 65% to 75% of all CTCL cases. It usually presents in the fifth to sixth decade, but can affect all ages, and is more common in males. The course tends to be more aggressive in African Americans. The current best estimate for the number of new MF cases in the United States is about 3000/year. Prevalence is much higher, due to the long survival.

Management Strategy

An effective treatment strategy depends on making an accurate and prompt diagnosis, which in early-stage MF can be challenging. The key histologic finding is epidermal invasion by atypical lymphoid cells with a convoluted “cerebriform” nucleus on histopathology in the proper clinical context. The International Society of Cutaneous Lymphomas (ISCL) has developed consensus standards for diagnosis based on a four-point scale, which is grounded on clinical, pathologic, and immunophenotypic criteria. Although imperfect, these consensus criteria should increase concordance in clinical practice and treatment recommendations. Often, multiple visits and skin biopsies are needed during the evolution of MF before the distinctive histologic features appear and the consensus ISCL standards for a diagnosis of MF are reached.

Once diagnosis is confirmed, determining the clinical stage is

important in the decision process for treatment. Staging aims at defining the specific sites of involvement and the overall disease burden for each patient, drives the management strategy, and predicts outcomes. The current staging system for MF and SS is the product of a joint effort of the ISCL and the European Organisation for Research and Treatment of Cancer (EORTC). This system, built on the original TNM classification developed by the U.S. National Cancer Institute in 1979, includes assessment of the peripheral blood compartment—hence TNMB—and allows optimal definition of SS and stratification of patients for clinical trials. This staging requires the integration of clinical findings and laboratory assays, such as flow cytometry and T-cell receptor (TCR) gene clonality analysis, that may not always be available and whose interpretation can be affected by confounding factors. Based on this classification, for clinical purposes, for decisions on treatment and discussion of survival, patients can be divided into “early stage” (IA–IIA) or “advanced stage” (IIB–IVB), with very different progression and survival rates.

MF typically demonstrates slow and predictable clinical progression, which can very often be inferred by the behavior and evolution of the lesions in the skin. Although many cases can be treated conservatively using skin-directed therapies, without resorting to systemic therapy, and enjoy a normal lifespan, a subset experience incomplete clearance and progress to more advanced stages with significant morbidity and mortality. Because MF is an indolent malignancy for most patients, long-term outcome studies based on large patient populations are required to estimate true rates of disease relapse, progression, transformation, and survival. Recent publications have addressed this need and offer a better assessment of the natural history of MF and SS.

Patients with MF should ideally be managed by a multidisciplinary team, including a dermatologist, a medical oncologist, a dermatopathologist familiar with skin lymphoma, and a radiation oncologist. The availability of nursing staff with expertise in dealing with skin care and skin malignancies is also desirable. This approach minimizes management errors and increases patient satisfaction. An initial consultation at a cancer center with an experienced cutaneous lymphoma team should be strongly considered. Finally, optimal patient support and education are paramount for an effective treatment strategy, and new patients should be encouraged to contact patient advocacy organizations that provide those resources.

Treatment objectives depend on the stage at diagnosis. For patients presenting with early-stage MF (IA–IIA), the goals are to control symptoms, clearing all visible disease in the skin; to slow or prevent progression; and to minimize distress, costs, and side effects. Avoidance of immunosuppressive therapies is a key objective. In a few patients, this can be achieved with minimal topical therapy (steroids). In most patients, however, this will require a coordinated effort and a sequence of skin-directed treatments to induce, and then maintain, a clinical response. Finally, in some patients, this objective will only be achieved with combinations of skin-directed and systemic therapies. Early studies have demonstrated that traditional cytotoxic chemotherapy, such as CHOP, does not improve survival compared with conservative skin-directed treatment regardless of stage of disease.

With many modalities available for skin-directed and systemic therapy, there are often several options for disease management, and the strategy for each patient may depend on the availability and accessibility of specific treatments. The goal is to initiate a treatment plan that the patient can adhere to reliably, to induce clinical response. Whether a cure is achievable in early-stage MF remains debatable. Nevertheless there are occasional patients who do not have recurrence of the disease after 5 to 10 years or longer. In most cases the disease recurs at some later point, with lesions often reappearing in the skin as patches or plaques, which often respond again to skin-directed treatments. Reinstitution of treatments that were previously effective is a wise and effective approach to patients with early-stage MF and is currently recommended in the NCCN guidelines.

In stage I MF, response may occasionally be achieved with *emollients*, but often *potent topical corticosteroids* are necessary. Other skin-directed therapies may be effective as monotherapy. These include *topical chemotherapy*, *retinoids*, or *phototherapy*. Phototherapy (UVB, UVA) or *photochemotherapy (PUVA)* is effective and can clear involved areas. In poorly responsive disease, combination treatment with topical and phototherapy may yield greater response. As disease stage advances, treatment strategy should adapt to reflect the disease velocity and burden. Applying more potent therapy can produce a complete response, but the chance of a complete response is reduced.

In stage II MF, achieving a clinical response is a higher priority based on reduced survival of patients in this group; thus combining a systemic therapy with skin-directed therapy leads to a higher

likelihood of response. Many patients will respond to combinations of topical treatment as before with *NBUVB* or *PUVA*. Also the addition of a systemic agent is beneficial in regimens such as *PUVA plus retinoids* or *PUVA plus interferon- α_{2a}* . Local radiotherapy is very effective at controlling persistent plaques or tumors, and *total skin electron beam (TSEB)* therapy is a good option when skin involvement is widespread and refractory to other approaches. *Topical chemotherapy (nitrogen mustard)* may still be effective.

For patients with advanced-stage MF (IIB–IVB) the goal of therapy is to induce remission, avoid any further reduction of immune competence, and prevent infections. Inability to realize these goals is likely to result in further disease progression, severe morbidity, and death. In these patients, treatment decisions are complex, and highly effective options for therapy remain limited.

Due to the natural history of MF, with multiple relapses and gradual progression over many years from limited (IA) to extensive (IB) patch/plaque disease, by the time patients have developed advanced-stage (IIB–IVB) disease they are likely to have been exposed to combined skin-directed and systemic therapy, most frequently *interferons* and *bexarotene*. Thus very few patients with advanced-stage MF are systemic therapy naïve, and the concept of “first-line” versus “second-line” choice may not easily apply. The best examples of chemo-naïve CTCL patients are those with tumor stage d’emblée and patients with SS. In all other cases, progression is subtle and does not occur en bloc. Patients have a gradation of skin lesions, exhibiting differential response to the ongoing therapy. The initial management of advanced-stage MF often focuses on strategies aimed at buttressing the existing treatment plan, rather than drastically changing direction. Skin-directed therapy is generally continued because most patients have areas of persistent patch/plaque disease that need to be optimally controlled. Likewise, some of the systemic drugs in use at the time of progression may be continued if there is evidence of residual, if inadequate, activity and they are well tolerated.

Older front-line drugs (*bexarotene*, *interferons*), shown to be effective in advanced-stage MF, are now being used in the treatment of earlier stages, in combination with skin-directed therapies, and newer drugs (*vorinostat*, *romidepsin*) are increasingly being introduced as primary choices in patients who progress from early to advanced-stage resistant disease. The drug *denileukin diftitox* is no longer available from the manufacturer in the United States, although a substitute

drug may become available in the future.

Patients with SS may be stage III to IVB. These patients present a particularly challenging problem due to drug resistance; severe, often intractable, pruritus; greater risk of infections; and difficulty with venous access, which may be required for infusional therapy, photopheresis, and disease monitoring. For patients with low tumor burden, *extracorporeal photopheresis (ECP)* can be effective, although durable complete responses are not common and its effect on survival is unclear. More frequently, patients with SS require combined modality therapy with *bexarotene*, *interferons*, and *ECP* (see article by Raphael et al.). Chemotherapy should rarely be used in the management of SS.

In stage IV MF outcomes are generally poor, regardless of the treatment. Incomplete response and quick relapses after treatment are the rule. *CHOP* and similar combination chemotherapy regimens can be used for patients who may need rapid debulking, followed by more effective long-term strategies, such as *allogeneic hematopoietic stem cell transplant*. *Local radiotherapy* is useful for bulky nodal disease and symptomatic skin lesions. Effective palliation requires consideration of symptoms such as nausea, constipation, pain, anorexia, infections, pruritus, and depression.

Specific Investigations

- Adequate skin biopsy reviewed by a pathologist with expertise in cutaneous lymphoma. Immunophenotype and TCR gene analysis are recommended, but not essential
- Complete physical examination, with assessment of % body surface area (BSA) and degree of pruritus
- Comprehensive metabolic panel, LDH, hematology, differential white blood cell count, Sézary cell count (if available), or peripheral blood flow cytometry (preferred) and TCR gene analysis if flow is abnormal or SS is suspected
- Imaging with CT or PET-CT scans is recommended in patients with tumor lesions and palpable lymph nodes
- Lymph node biopsy with histology, immunophenotype, and TCR gene analysis, if enlarged
- HTLV-1 serology in populations at risk

The diagnostic studies and initial clinical assessment in patients

with MF can be complex. In the United States, the NCCN publishes guidelines for the diagnosis and therapy of MF and SS. Similar guidelines are produced by the European Society of Medical Oncology (ESMO) and other national societies in Europe. The NCCN guidelines are updated annually and represent the consensus view of a panel that includes dermatologists, medical oncologists, radiation oncologists, and pathologists. The NCCN guidelines suggest a combination of essential and nonessential investigations, which the treating physician can select as clinically indicated in individual patients.

Many of the clinical assessment tools and laboratory investigations have been recently reviewed and integrated into new clinical end points and response criteria for MF, through a collaborative effort of the ISCL, EORTC, and the United States Cutaneous Lymphoma Consortium (USCLC).

Defining early mycosis fungoides

Pimpinelli N, Olsen EA, Santucci M, Vonderheid E, Haeffner AC, Stevens S, et al. *J Am Acad Dermatol* 2005; 53: 1053–63.

Revisions to the staging and classification of mycosis fungoides and Sézary syndrome: a proposal of the International Society for Cutaneous Lymphomas (ISCL) and the cutaneous lymphoma task force of the European Organisation of Research and Treatment of Cancer (EORTC)

Olsen E, Vonderheid E, Pimpinelli N, Willemze R, Kim Y, Knobler R, et al. *Blood* 2007; 110: 1713–22.

These papers describe a consensus approach to the diagnosis and clinical staging of MF/SS. These focus on MF/SS and exclude other types of CTCL and the cutaneous B-cell lymphomas (CBCL), which are staged differently. Several retrospective studies of the applicability of the ISCL criteria have been published, and they support their validity across different patient populations. The two largest studies by Agar et al. and Talpur et al. are discussed later.

Clinical end points and response criteria in mycosis fungoides and Sézary syndrome: a consensus statement of the International Society for Cutaneous Lymphomas (ISCL), the United States Cutaneous Lymphoma Consortium (USCLC), and the Cutaneous Lymphoma Task Force of the European

Organisation for Research and Treatment of Cancer (EORTC)

Olsen EA, Whittaker S, Kim YH, Duvic M, Prince HM, Lessin SR, et al. *J Clin Oncol* 2011; 29: 2598–607.

This paper, together with the earlier one (2007) by Olsen et al., provides a complete set of guidelines and rules not only to diagnose and stage disease in MF/SS, but also to assess responses to treatment. Standardized response criteria are absolutely essential for clinical trials and to facilitate communication among physicians from different institutions.

Survival outcomes and prognostic factors in mycosis fungoides/Sézary syndrome: validation of the revised International Society for Cutaneous Lymphomas/European Organisation for Research and Treatment of Cancer staging proposal

Agar NS, Wedgeworth E, Crichton S, Mitchell TJ, Cox M, Ferreira S, et al. *J Clin Oncol* 2010; 28: 4730–9.

A multicenter cohort of 1502 British CTCL patients observed over 1980 to 2009 and classified according to the current ISCL/EORTC criteria. The large size and the long-term follow-up allowed a better estimate of rates of progression (34%) and disease-specific mortality (26%). These rates suggest that long-term morbidity and mortality may be greater than expected. The rate of progression in patients with stage IA and IB at 20 years may be higher than previously recognized (18% and 47%, respectively). Furthermore, a significant difference in survival and progression was noted for patients with early-stage disease having patches alone (T1a/T2a) compared with those having patches and plaques (T1b/T2b). Multivariate analysis also showed that advanced skin (T) stage, presence of the tumor clone in the peripheral blood without Sézary cells (B0b), increased LDH, and folliculotropic MF were independent predictors of survival and progression.

Long-term outcomes of 1,263 patients with mycosis fungoides and Sézary syndrome from 1982 to 2009

Talpur R, Singh L, Daulat S, Liu P, Seyfer S, Trynosky T, et al. *Clin Cancer Res* 2012; 18: 5051–60.

A cohort of patients at the MD Anderson Cancer Center between 1982 and 2009, mean age at diagnosis ~55 years, ~71% with early stage. Disease progression for early-stage patients (12%) and disease-

specific mortality for the entire cohort (8.1%) were lower than those observed by Agar et al. Risk factors associated with progression or deaths were advanced age, plaque stage, LDH, and tumor area.

Second lymphomas and other malignant neoplasms in patients with mycosis fungoides and Sézary syndrome: evidence from population-based and clinical cohorts

Huang KP, Weinstock MA, Clarke CA, McMillan A, Hoppe RT, Kim YH. Arch Dermatol 2007; 143: 45–50.

This study analyzed Stanford (1973–2001) and SEER-9 registry data (1984–2001) for a cumulative population of >2200 patients and estimated relative risk for various malignancies, excluding nonmelanoma skin cancers, by using the standardized incidence ratio (SIR). In both cohorts there was a very significant increase in the risk of Hodgkin lymphoma. The risk of non-Hodgkin lymphoma was increased in the SEER-9 cohort. Cumulative incidence of second malignancies in the Stanford cohort was estimated to be 10% at 8.6 years. Therefore updated SEER (population based) and Stanford (clinic based) data confirm increased risk of lymphoma in patients with MF/SS.

A look at the National Comprehensive Cancer Network guidelines for cutaneous lymphomas

Porcu P. Clin Lymphoma Myeloma Leuk 2010; 10(Suppl. 2): S109–11.

This article highlights the importance of a multidisciplinary approach in the management of MF/SS and the general strategy of gradual escalation of systemic therapy, leaving cytotoxic drugs for later. In addition, the strategy of “looping back” is integral to the NCCN guidelines. This concept is based on the observation that disease relapse or progression in MF/SS does not necessarily imply advancement to a higher stage (i.e., from T1 to T2, or T3). Rather, patients who start with T1 disease and achieve remission may relapse back to T1 disease.

First-Line Therapies

Early stage (IA–IIA)

• Emollients	E
• Topical corticosteroids	B
• UVB or PUVA	B
• Excimer 308-nm laser	D
• Photodynamic therapy	D
• Imiquimod 5% cream	D
• Topical chemotherapy	B
• Local radiotherapy	B
• Topical bexarotene and other retinoids	B

Advanced stage (IIB–IVB)

• Oral bexarotene and other retinoids	B
• Interferons	B
• Extracorporeal photopheresis (ECP)	B
• Low-dose methotrexate	B
• PUVA ± retinoids	C
• PUVA ± interferons	C
• Denileukin diftitox	A

Topical steroids for mycosis fungoides – experience in 79 patients

Zackheim HS, Kashani-Sabet M, Smita A. Arch Dermatol 1998; 134: 949–54.

Topical corticosteroids are a safe first-line treatment. However, if there is poor clinical response and worsening of the disease, then additional treatment is valuable. Steroids are most often effective for the poikilodermatous variant of MF. Thicker lesions are often less responsive and benefit from additional skin-directed treatment.

Long-term follow-up of patients with early-stage cutaneous T-cell lymphoma who achieved complete remission with psoralen plus UV-A monotherapy

Querfeld C, Rosen ST, Kuzel TM, Kirby KA, Roenigk HH, Prinz BM, et al. Arch Dermatol 2005; 141: 305–11.

A single-center analysis of patients with early MF who achieved long-term remission with PUVA. Sixty-six of 104 patients with clinical stages IA to IIA MF achieved complete remission (CR) after PUVA monotherapy between 1979 and 1995. The long-term survival rates at 5, 10, and 15 years were 94%, 82%, and 82%, respectively, in patients with stage IA, and 80%, 69%, and 58% in patients with stage IB/IIA. The major complication from PUVA was that one third of the patients developed signs of chronic photodamage and secondary cutaneous malignancies.

PUVA is an effective treatment for MF capable of inducing long-term remissions and perhaps, in some cases, “cure.”

Narrowband UVB and psoralen-UVA in the treatment of early-stage mycosis fungoides: a retrospective study

Diederer PV, van Weelden H, Sanders CJ, Toonstra J, van Vloten WA. J Am Acad Dermatol 2003; 48: 215–9.

A retrospective study comparing NBUVB and PUVA examining response to treatment, relapse-free interval, and irradiation dose in 56 patients with stage IA and IB MF. A total of 21 patients were treated with narrowband UVB (311 nm); 35 were treated with PUVA. Narrowband UVB led to complete remission in 17 (81%) and partial remission in 4 (19%), and none showed progressive disease. PUVA treatment led to complete remission in 25 (71%) and partial remission in 10 (29%), and none showed progressive disease. Thus NBUVB is effective for patients with early-stage MF.

Monochromatic excimer light (308 nm) in patch-stage IA mycosis

fungoides

Mori M, Campolmi P, Mavilia L, Rossi R, Cappugi P, Pimpinelli N. *J Am Acad Dermatol* 2004; 50: 943–5.

This was effective in the treatment of patch stage IA MF. The authors treated seven patch lesions in four patients with unequivocal diagnosis of MF. All lesions achieved complete clinical and histologic remission. The total dose ranged from 5 to 9.3 J/cm² (mean 7.1 J/cm²; median 7 J/cm²), and remission was maintained with a follow-up of 3 to 28 months without significant side effects reported.

Photodynamic therapy with methyl-aminolaevulinic acid for mycosis fungoides

Kim ST, Kang DY, Kang JS, Baek JW, Jeon YS, Suh KS. *Acta Derm Venereol* 2012; 92: 264–8.

Ten patients received two sessions of PDT at 1-week intervals. Five showed complete response on biopsy, and two showed partial responses. During follow-up (8–31 months), six of the seven patients remained in stable remission. For patients with limited skin involvement, likely <5%, PDT may be an alternative option to consider.

Treatment of patch and plaque stage mycosis fungoides with imiquimod 5% cream

Deeths MJ, Chapman JT, Dellavalle RP, Zeng C, Aeling JL. *J Am Acad Dermatol* 2005; 52: 275–80.

This treatment showed safety and efficacy in patch and plaque stage MF in six patients, stage IA to IIB, using topical imiquimod 5% cream three times per week for 12 weeks in an open-label pilot study. After response with biopsies pretreatment and posttreatment, there was a 50% response with histologic clearance of disease in index lesions. Irritation at the application site was seen in patients responding to treatment.

Long-term efficacy, curative potential, and carcinogenicity of topical mechlorethamine chemotherapy in cutaneous T cell lymphoma

Vonderheid EC, Tan ET, Kantor AF, Shrager L, Micaily B, Van-Scott EJ. *J Am Acad Dermatol* 1989; 20: 416–28.

A retrospective review of 331 patients, 195 with initial complete response with stage I to IVA. Of these patients, 65 had remission

greater than 4 years, and 35 greater than 8 years. Complete responses lasting more than 8 years were also described in nine patients with stage II/III. Patients often continued maintenance therapy for an average of 3 years. Risks of nitrogen mustard include sensitization to the application, squamous and basal cell carcinoma, Hodgkin disease, and colon cancer.

Topical mechlorethamine (nitrogen mustard), 10 mg in 60 mL water, or as ointment, is effective in stage I and II MF. As with phototherapy, earlier-stage disease responds more quickly and for longer. Topical carmustine (BCNU) is also effective and causes less contact allergic dermatitis, but each treatment is limited to 3 to 4 weeks because of the risk of myelosuppression, which may be cumulative.

Phase 1 and 2 trial of bexarotene gel for skin-directed treatment of patients with cutaneous T-cell lymphoma

Breneman D, Duvic M, Kuzel T, Yocum R, Truglia J, Stevens VJ. Arch Dermatol 2002; 138: 325–32.

Sixty-seven patients with stage IA to IIA CTCL used this topical retinoid in incremental doses. There was a 21% complete response and 42% partial response. The median time to relapse was 23 months.

Topical 1% bexarotene gel has been approved by the Food and Drug Administration (FDA) for refractory or persistent stage IA to IIA MF. Local irritation can occur, particularly with increased frequency of application. Treatment is initially applied on alternate days, increasing gradually to a maximum of four times daily.

Comparison of pegylated interferon α -2b plus psoralen PUVA versus standard interferon α -2a plus PUVA in patients with cutaneous T-cell lymphoma

Hüsken AC, Tsianakas A, Hensen P, Nashan D, Loquai C, Beissert S, et al. J Eur Acad Dermatol Venereol 2012; 26: 71–8.

This 17-patient retrospective study compared the safety and efficacy of pegylated interferon- α 2b (1.5 μ g/kg weekly) versus standard IFN- α (9 MIU three times a week) in combination with PUVA. Myelosuppression and liver toxicity were more frequent with PEG-IFN- α 2b, whereas fatigue and other adverse events leading to discontinuation were more frequent with standard IFN- α 2a. The response rate in the PEG-IFN- α 2b plus PUVA group seemed superior.

Predictors of response to extracorporeal photopheresis in

advanced mycosis fungoides and Sézary syndrome

McGirt LY, Thoburn C, Hess A, Vonderheid EC. Photodermatol Photoimmunol Photomed 2010; 26: 182–91.

Sézary syndrome: immunopathogenesis, literature review of therapeutic options, and recommendations for therapy by the United States Cutaneous Lymphoma Consortium (USCLC)

Olsen EA, Rook AH, Zic J, Kim Y, Porcu P, Querfeld C, et al. J Am Acad Dermatol 2011; 64: 352–404.

Olsen et al. summarize published treatment options for SS. Extracorporeal photopheresis (ECP), a procedure that treats pheresed blood with Oxsoresalen, received FDA approval in 1988 as a medical device for the treatment of CTCL. ECP is well tolerated and should be considered for all patients with SS. Treatment is given every 2 to 4 weeks, with responses typically seen at 3 to 6 months. Oral bexarotene and interferons should be combined with ECP in all but those cases where the peripheral blood burden of Sézary cells is minimal.

High clinical response rate of Sézary syndrome to immunomodulatory therapies: prognostic markers of response

Raphael BA, Shin DB, Suchin KR, Morrissey KA, Vittorio CC, Kim EJ, et al. Arch Dermatol 2011; 147: 1410–5.

Outcomes in 98 patients with SS according to ISCL/EORTC criteria seen over a 25-year period at the University of Pennsylvania. Patients were treated with at least 3 months of ECP and one or more systemic agents. A total of 73 patients had significant improvement with multimodality therapy: 30% had complete response, with clearing of all disease. Lower CD4/CD8 ratio and median percentage of CD4+/CD26– and CD4+/CD7– cells at baseline predicted for complete response. Eosinophilia was shown in one study to predict a favorable response to ECP, but this remains to be confirmed.

Second-Line Therapies

Early stage (IA–IIA)

• Retinoids plus PUVA	B
• Interferons	B
• Total skin electron beam (TSEB) radiotherapy	B
• Oral bexarotene	B
• Low-dose methotrexate	B

Advanced stage (IIB–IVB)

• TSEB radiotherapy	B
• Vorinostat	B
• Depsipeptide	B
• Brentuximab vedotin	B
• Alemtuzumab	B
• Liposomal doxorubicin	B
• Gemcitabine	B
• Pralatrexate	B
• Purine analogs	B

Phase IIb multicenter trial of vorinostat in patients with

persistent, progressive, or treatment refractory cutaneous T-cell lymphoma

Olsen EA, Kim YH, Kuzel TM, Pacheco TR, Foss FM, Parker S, et al. *J Clin Oncol* 2007; 25: 3109–15.

A pivotal, open-label, phase II trial that enrolled 74 patients with stage >IB CTCL who had failed two systemic therapies (one of which must have been bexarotene). Patients received vorinostat 400 mg daily, with planned dose reductions for toxicity. The objective response rate, assessed by the Severity-Weighted Assessment Tool (SWAT), was 30%, and the median response duration was ~6 months.

Final results from a multicenter, international, pivotal study of romidepsin in refractory cutaneous T-cell lymphoma

Whittaker SJ, Demierre MF, Kim EJ, Rook AH, Lerner A, Duvic M, et al. *J Clin Oncol* 2010; 28: 4485–91.

Romidepsin was administered as a 4-hour infusion (14 mg/m²) on days 1, 8, and 15 of a 28-day cycle. The average number of cycles received by the patients was 4, and the median number of doses was 12. The objective response rate was 34%, the complete response rate was 6%, and the median duration of response was >12 months. In pruritus assessment, 43% of the patients experienced “clinically significant” improvement. As for vorinostat, the most common adverse effects were fatigue, nausea, vomiting, anorexia, and thrombocytopenia. Although electrocardiographic changes were common, no serious cardiac events were observed.

Romidepsin was approved by the FDA in 2009 for relapsed/refractory CTCL based on two phase II trials (Whittaker et al.) that enrolled a total of 167 patients with relapsed or refractory CTCL.

Vorinostat and romidepsin are FDA-approved histone deacetylase (HDAC) inhibitors (HDACi), a promising class of drugs with activity in CTCL. Vorinostat, an oral agent, was approved in 2006 for relapsed and refractory CTCL. Romidepsin, an intravenous agent, was approved in 2009 for CTCL and more recently in 2011 for the treatment of peripheral T-cell lymphoma (PTCL). These agents modulate chromatin condensation and potentially alter abnormal gene transcription and expression in cancer cells. They affect multiple functions in cancer cells, including proliferation, apoptosis, and angiogenesis. A subset of T-cell lymphomas, including MF and SS, may be sensitive to the antitumor effect of HDACi. Although not as myelosuppressive as conventional chemotherapy, HDACi may have some

immune-suppressive effects, altered electrolytes, and association with thrombocytopenia.

Phase II investigator-initiated study of brentuximab vedotin in mycosis fungoides and Sézary syndrome with variable CD30 expression level: a multi-institution collaborative project

Kim YH, Tavallae M, Sundram U, Salva KA, Wood GS, Li S, et al. J Clin Oncol 2015; 33: 3750–8.

Brentuximab vedotin (SGN-35) is an anti-CD30 monoclonal antibody conjugated to monomethyl auristatin E, which releases the cytotoxic moiety intracellularly. The antibody is given IV every 3 weeks at 1.8 mg/mg. The objective response was 70%. Limiting side effects include peripheral neuropathy. The response rate was not necessarily dependent on CD30 expression.

Alemtuzumab for relapsed and refractory erythrodermic cutaneous T-cell lymphoma: a single institution experience from the Robert H. Lurie Comprehensive Cancer Center

Querfeld C, Mehta N, Rosen ST, Guitart J, Rademaker A, Gerami P, et al. Leuk Lymphoma 2009; 50: 1969–76.

Low-dose intermittent alemtuzumab in the treatment of Sézary syndrome: clinical and immunologic findings in 14 patients

Bernengo MG, Quaglino P, Comessatti A, Ortoncelli M, Novelli M, Lisa F, et al. Haematologica 2007; 92: 784–94.

Alemtuzumab (campath-1H) is a humanized monoclonal antibody against CD52, a molecule expressed on almost all leukocytes, including malignant T cells and B cells. The drug is approved for refractory chronic lymphocytic leukemia (CLL), but has activity in T-cell lymphoma and leukemia. The phase II study by Querfeld et al. specifically investigated the activity of alemtuzumab in patients with erythrodermic CTCL (including SS). Ten patients received alemtuzumab intravenously using an escalating dose regimen with a final dose of 30 mg three times weekly for 4 weeks followed by subcutaneous administration for 8 weeks. Nine patients were treated with only the subcutaneous or IV dosing. The overall response rate was 84%, with nine (47%) complete and seven (37%) partial remissions. The median follow-up was 24 months (range, 6–62+ months). Median overall survival was 41 months, whereas median progression free survival was 6 months. Toxicities included myelosuppression and infections, but most were moderate and transient. Although the conventional dose of alemtuzumab is 30 mg thrice

weekly, Bernengo et al. studied a lower-dose intermittent schedule with the goal of avoiding excessive toxicity. The drug, given subcutaneously, was held once circulating Sézary cells fell below a certain threshold and resumed when the Sézary cell count increased. This approach appears to be safer, but it needs to be compared with the conventional schedule for efficacy.

Third-Line Therapies

• Topical bexarotene gel and other retinoids	B
• Single-agent chemotherapy	B
• Combination chemotherapy	B
• Allogeneic bone marrow transplantation	D
• Liposomal doxorubicin	B
• Gemcitabine	B
• Pralatrexate	B
• Purine analogs	B

Total skin electron beam and non-myeloablative allogeneic hematopoietic stem-cell transplantation in advanced mycosis fungoides and Sézary syndrome

Duvic M, Donato M, Dabaja B, Richmond H, Singh L, Wei W, et al. J Clin Oncol 2010; 28: 2365–72.

Allogeneic hematopoietic stem cell transplantation (HSCT) leverages the antitumor immune effect of the allograft, known as *graft versus lymphoma (GVL) effect*. However, allogeneic HSCT has significant mortality (up to 30%). Selecting the best time window, remission-inducing therapy, and condition regimen for patients with refractory CTCL is important. Duvic et al. studied the use of TSEBR in the preparatory regimen for allogeneic HSCT. Nineteen patients with heavily pretreated advanced CTCL and median age 50 years received TSEBR followed by fludarabine and melphalan conditioning and

allogeneic HSCT between 2001 and 2008. Eighteen patients experienced engraftment, and 15 achieved full donor chimerism. Twelve experienced graft-versus-host disease. Four patients died in remission from transplant complications, and two died from progressive disease. Five of eight patients who relapsed in the skin regained complete response with reduced immunosuppression or donor lymphocyte infusions. Eleven of 13 were in complete remission, with median follow-up of 19 months.

Myiasis

Chen "Mary" Chen, and Robert G. Phelps

Myiasis is the infestation of human and animal tissue by the larval or pupal stages of two-winged true flies (Diptera), most commonly the *Dermatobia hominis* (botfly) and *Cordylobia anthropophaga* (tumbu fly). It is typically found in tropical and subtropical regions and is rare elsewhere. Its development is associated with poor hygiene, poor

housing conditions, and overall debilitated state. Patients present with enlarging insect bites, ulceration, furuncle, or wound ulceration with sensation of irritation and lancinating pain. Larvae infest necrotic or viable skin but may also infest the eyes, ears, nose, and gastrointestinal (GI) or genitourinary (GU) sites.

Management Strategy

Myiasis was a major public health concern in the early twentieth century. Improvements in hygiene and wound care have significantly decreased its incidence. Nosocomial outbreaks, however, continue to occur sporadically. Manner of transmission differs depending on the species of flies. Furuncular myiasis is the most common and occurs through larvae burrowing into the skin.

Therapy objectives include complete larvae removal and prevention of secondary infestations and bacterial infections. Risk of exposure is linked to travel to Central and South America and parts of Africa. Visitors to rural regions should be *covered at all times with long-sleeved garments and hats*. Because many larvae vectors include bloodseeking arthropods, sleeping with a *mosquito net* at night is recommended. Liberal use of *insect repellents* is likewise useful. All clothing should be *hot ironed and thoroughly dried* to remove any residual eggs. To prevent barefoot transmission of fly eggs from the soil, *appropriate footwear* should be utilized. Wound myiasis can be prevented using *antiseptic techniques*. Wound cleaning, irrigation, and regular dressing changes are usually sufficient. As a precaution, patients with large wounds should sleep indoors only and with windows closed.

Once infestation has occurred, therapy consists of *surgical removal of all larvae* with minimal trauma to the organisms. Simple infiltration of the area with lidocaine and surgical removal is standard of care when few organisms are present. *Occlusive therapy* (using petroleum jelly or strips of bacon), inducing larvae to protrude their abdomen to reach air, may be helpful when many larvae are present. Careful technique must be used to extract the larvae whole; otherwise a considerable foreign body reaction may ensue. If there is secondary pyogenic infection, this should be treated with antibiotics. Supplemental treatments including *isopropyl alcohol*, *Dakin solution*, *iodine*, or *hydrogen peroxide* can be included in wound care. Anecdotal reports suggest use of *topical and systemic ivermectin* for complicated

conditions (extensive or multiple lesions, substantial involvement of orbital or oral cavities, or failure of surgical extraction).

Specific Investigations

- Detailed travel history
- Morphologic and molecular identification of the parasite

A blow to the fly—*Lucilia cuprina* draft genome and transcriptome to support advances in biology and biotechnology

Anstead CA, Batterham P, Korhonen PK, Young ND, Hall RS, Bowles VM, et al. *Biotechnol Adv* 2016; 34: 605–20.

Draft genome and transcriptome of the blow fly gives new and global insights into its biology, interactions with the host animal, and aspects of insecticide resistance at the molecular level. The genetic resource will also aid the design of new and improved interventions for myiasis.

Molecular identification of two species of myiasis-causing *Cuterebra* by multiplex PCR and RFLP

Noel S, Tessier N, Angers B, Wood DM, Lapointe FJ. *Med Vet Entomol* 2004; 18: 161–6.

The fly larvae should be extracted whole and specific identification attempted. Each larva may molt and have several instars, each with a slightly different morphology, complicating identification. The adult fly should be identified, if possible. Consultation with an entomologist in difficult cases is helpful. Scanning electron microscopy and multiplex polymerase chain reaction (PCR) may aid identification.

Identification of subcutaneous myiasis using bedside emergency physician performed ultrasound

Schechter E, Lazar J, Nix ME, Mallon WK, Moore CL. *J Emerg Med* 2011; 40: e1–3.

Ultrasound diagnosis of patient with *C. anthropophaga* maggot infestation with hyperechoic areas.

First-Line Therapies

Surgical therapy

• Surgical removal with local anesthesia with or without adjuvant suffocation techniques	D
--	---

Asphyxiation therapy

• Vaseline therapy	E
• Bacon therapy	E
• Pork fat therapy	E
• Hair gel therapy	E
• Occlusion with <i>chimo</i> (pastelike form of smokeless tobacco)	E
• Small wad of cotton soaked in the sap of the <i>Thevetia ahouai</i> (Apocynaceae) tree	E

Myiasis in travelers

Lachish T, Marhoom E, Kosta Y, Mumcuoglu KY, Tandlich M, Schwartz E. J Travel Med 2015; 22: 232–6.

This retrospective observational study identified 90 patients diagnosed with myiasis from posttravel clinics in Israel. Seventy-six percent of the cases were managed by manual extraction, which can be performed after covering the central pore of the lesion with a sealing ointment such as paraffin.

Myiasis: a traveler's dilemma

Mammino J, Lal K. J Clin Aesthet Dermatol 2013; 6: 47–9.

Scalp myiasis successfully extracted with excisional biopsy technique under local anesthesia. This assures that the larvae, along with the subcutaneous tissue surrounding the implanted larvae, is removed.

Cutaneous myiasis

Krajewski A, Allen B, Hoss D, Patel C, Chandawarkar RY. J Plast Reconstr Aesthet Surg 2009; 62: e383–6.

The favored treatment modality is complete surgical extraction of larvae from the lesion to prevent the risk of secondary infection associated with retained larvae.

One catches not only mice with bacon. An atraumatic treatment for cutaneous myiasis

Schulte C, Schunk M, Krebs B. Dtsch Med Wochenschr 2002; 127: 266–8.

A piece of raw bacon, serving as occlusion material, was fixated on the affected skin for 2 hours. The larvae emerged due to oxygen deficiency. After retraction of the bacon it was possible to grasp the emerged end of the larvae with tweezers and pull them out completely.

Alternatives to bacon therapy

Biggar RJ. JAMA 1994; 271: 901–2.

The authors use Vaseline over the wound to smother the larvae, and they emerge spontaneously.

Traditional methods encourage the larva to exit on its own, taking advantage of its need for oxygen, by using various occlusive dressings to suffocate it.

Dermal myiasis: the porcine lipid cure

Sauder DN, Hall RP, Wurster CF. Arch Dermatol 1981; 117: 681–2.

Pork fat was placed on the lesions and covered with an occlusive tape, and the emerging larvae were extracted with forceps.

Second-Line Therapies

• Systemic ivermectin	E
• Topical ivermectin	E
• Chlorhexidine gluconate rinses	E
• Pyrantel pamoate	E
• Radiation therapy	E
• Chloroform/ether	E
• Mineral turpentine	E
• Ethanol spray	E
• Oil of betel leaf	E
• Mineral turpentine	E

Oral myiasis: a rare case report and literature review

Shikha S, Prasad Guru R, Ashutoshdutt P, Meenakshi S. J Dent (Tehran) 2015; 12: 456–9.

For extensive disease in the oral cavity, the treatment was given systemic ivermectin 6 mg once daily for three days and oral amoxicillin 250 mg three times daily for 7 days. Mouth rinse twice daily with 0.2% chlorhexidine gluconate for 15 days under supervision.

Use of ivermectin in the treatment of orbital myiasis caused by *Cochliomyia hominivorax*

De Tarso P, Pierre-Filho P, Minguuini N, Pierre LM, Pierre AM. Scand J Infect Dis 2004; 36: 503–5.

One dose of ivermectin (200 µg/kg) was used for infestation with *Hypoderma lineatum*, and led to spontaneous migration of the

maggots.

Myiasis owing to *Dermatobia hominis* in a HIV-infected subject: treatment by topical ivermectin

Clyti E, Nacher M, Merrien L, El Guedj M, Roussel M, Sainte-Marie D, Couppié P. Int J Dermatol 2007; 46: 52–4.

Human immunodeficiency virus (HIV) infection did not modify the pathogenicity of myiasis but did contribute unusually extensive and voluminous inflammatory nodules. Use of topical ivermectin killed the larvae and facilitated their extraction.

Myiasis: successful treatment with topical ivermectin

Victoria J, Trujillo R, Barreto M. Int J Dermatol 1999; 38: 142–4.

Four patients presented with traumatic myiasis caused by *C. hominivorax* with 50–100 larvae each. One topical treatment with 1% ivermectin in a propylene glycol solution was applied to the affected area. The topical solution was left for 2 hours, followed by gentle washing with normal saline or sterile water. Within 1 hour, almost all larvae stopped moving, and within 24 hours, all died.

Nasal myiasis: a case report

White ZL, Chu MW, Hood RJ. Ear Nose Throat J 2015; 94: e24–5.

Two patients without necrosis or large masses were successfully treated with conservative therapy, consisting of a single dose of pyrantel pamoate, daily sinus irrigation with saline, and daily bedside endoscopic debridement.

Head and neck myiasis, cutaneous malignancy, and infection: a case series and review of the literature

Jennifer A, Villwock JA, Harris TM. J Emerg Med 2014; 47: e37–41.

One patient in the case series received radiation beam therapy for her concurrent squamous cell carcinoma, which serendipitously eradicated the larvae infection. Use of this modality for myiasis treatment has not been previously reported.

Dissanayake, larvicidal effects of mineral turpentine, low aromatic white spirits, aqueous extracts of *Cassia alata*, and aqueous extracts, ethanolic extracts and essential oil of betel leaf (*Piper betle*) on *Chrysomya megacephala*

Kumarasinghe SP, Karunaweera ND, Ithalamulla RL, Arambewela LS.

Int J Dermatol 2002; 41: 877–80.

Myxoid cyst

David de Berker

Myxoid cysts are also known as *digital mucus cysts* or *pseudocysts* and represent a ganglion of the distal interphalangeal joint. They arise in different forms in soft tissues, typically above or distal to the distal interphalangeal joint. The most common presentation is as a translucent nodule on the dorsum of the digit. Additional patterns of presentation include as a pseudofibroma emerging between the proximal nail fold and dorsal aspect of the nail plate, or as a tumor beneath the nail matrix causing a red lunula, increased transverse curvature of the nail, and sometimes its disintegration.

Management Strategy

Myxoid cysts contain gelatinous material that has escaped from the distal interphalangeal joint. Treatment can involve evacuation combined with measures to prevent further escape from the joint. *Simple drainage* through an incision can achieve the first, but normally there is recurrence within a few weeks. Measures to prevent the further accumulation of fluid are directed at reducing joint pathology or blocking the pathway of escape of fluid. The first category includes the use of *injected triamcinolone*, which might reduce synovial inflammation and the pressure of fluid within the joint, and *surgery* for osteophytes. Osteophytes appear to weaken the joint capsule and possibly contribute to joint pathology and synovial fluid production. Their removal is associated with resolution of the myxoid cyst but at risk of alteration of joint function.

Blockage of the path of fluid escape is achieved by a range of traumatic and scarring procedures. The challenge is to produce an effective scar over the joint without excess morbidity or a long-term nail dystrophy.

A practical compromise of morbidity, complexity of treatment, and efficacy is to employ *cryosurgery* in the first instance. This is best used with a distal block using lidocaine or bupivacaine. The cyst is then incised and drained. Two freezes of between 10 and 20 seconds with liquid nitrogen are given, with a complete thaw in between. Over the next 2 weeks the wound is dressed. This results in success in about 50% of cases involving fingers. Those that fail can be retreated in the same way or proceed to surgery. Morbidity is least when there is *precise surgery* to the path of fluid escape. This can be identified by methylene blue injection into the joint and then raising a flap in a distal-to-proximal path, containing the cyst in the roof of the flap. The pathway is dyed and can be tied with absorbable ligature. The flap is sutured back in place, and success is reported as 94% in the fingers. In some instances patient preference or medical considerations may mean that surgery is the first-line therapy.

Specific Investigations

- Transillumination
- Pricking and expression of gelatinous material
- Ultrasound
- Magnetic resonance imaging (MRI)

Transillumination is a useful clinical aid. Where there is diagnostic doubt, simple incision can be helpful to demonstrate the gelatinous material. Alternatively, high-resolution ultrasound or MRI can be employed. The first can only help define whether the structure is cystic or not. The latter provides better anatomic definition and in over 80% of cases allows location of the pedicle communicating between the cyst and joint. Plain x-ray may reveal osteophytes of osteoarthritis, but this will not usually alter treatment.

Benign tumors and pseudotumors of the nail: a novel application of sonography

Wortsman X, Wortsman J, Soto R, Saavedra T, Honeyman J, Sazunic I, et al. J Ultrasound Med 2010; 29: 803–16.

MR imaging of digital mucoid cysts

Drapé JL, Idy Peretti I, Goettmann S. Radiology 1996; 200: 531–6.

First-Line Therapies

• Cryosurgery	B
• Puncture	D
• Laser therapy	C
• Sclerosant	C

Myxoid cysts of the finger: treatment by liquid nitrogen spray cryosurgery

Dawber RPR, Sonnex T, Leonard J, Ralphs I. Clin Exp Dermatol 1983; 8: 153–7.

Fourteen patients were treated with two 30-second freezes and no evacuation of the cyst. Follow-up was between 14 and 40 months, with an 86% cure rate. One patient had a significant nail dystrophy as a long-term complication.

Removal of the overlying cyst or evacuation of the contents might reduce the duration of cryosurgery needed. Longer freeze times increase morbidity and risk of scarring.

Specific indications for cryosurgery of the nail unit

Kuflik EG. J Dermatol Surg Oncol 1992; 18: 702–6.

Forty-nine patients were treated with a range of single cryosurgical doses, from 20 to 30 seconds using open spray, and 30 to 40 seconds using the cryoprobe. This was combined with curettage in 23 patients and simple deroofting in the remainder. There was resolution in 63% over the follow-up period of 1 to 60 months.

A simple technique for managing digital mucous cysts

Epstein E. Arch Dermatol 1979; 115: 1315–6.

Repeated puncture of myxoid cysts in 40 patients led to resolution in 72% after two to five treatments, but no follow-up period is given.

Blunt force may be an effective treatment for ganglion cysts

Trivedi NN, Schreiber JJ, Daluiski A. HSS J 2016; 12: 100–4.

Review of reports of aspiration treatment suggests overall success rate of 53%.

Blunt force alone may be sufficient as reported by Trivedi et al. based on online self-reporting. But details are not well documented, as it is usually done as self-care.

Treatment of digital myxoid cysts with carbon dioxide laser vaporization

Huerter CJ, Wheeland RG, Bailin PL, Ratz JL. J Dermatol Surg Oncol 1987; 13: 723–7.

Carbon dioxide laser cured 10 patients with follow-up of 35 months.

Treatment of digital mucous cysts with intralesional sodium tetradecyl sulfate injection

Park SE, Park EJ, Kim SS, Kim CW. *Dermatol Surg* 2014; 40: 1249–54.

The sclerosant sodium tetradecyl sulfate 1% (fingers) or 3% (toes) 0.2 to 0.5 mL was injected into a lesion after aspiration of the gel. It was then repeated every 4 weeks if the cyst persisted, up to 7 times (mean 2.3), with eventual resolution in 80% and subsequent relapse in a further 2 patients (10%) after a mean follow-up of 16 months (range 2–38 months).

Treatment of 63 subjects with digital mucous cysts with percutaneous sclerotherapy using polidocanol

Esson GA, Holme SA. *Dermatol Surg*. 2016; 42: 59–62.

Three percent polidocanol (0.02–0.5 mL) is a sclerosant that can be used in a similar way with similar results.

Some reports have described necrosis of the nail fold, but this is seldom extensive. The theoretical complication of sclerosant entering the joint does not appear to occur.

Second-Line Therapy

• Surgery	B
-----------	---

Marginal osteophyte excision in treatment of mucous cysts

Eaton RG, Dobranski AI, Littler JW. *J Bone Joint Surg* 1973; 55A: 570–4.

Forty-four patients with surgery entailing tracing of the communication between cyst and joint, excision of the cyst, and in some instances surgery to the osteophytes provided success in 43 of 44 patients, with follow-up of between 6 months and 10 years.

There is a theoretical possibility of operating on the osteophytes alone, leaving the cyst in place and allowing it to involute once the precipitating pathology has been removed.

Etiology and treatment of the so-called mucous cyst of the finger

Kleinert HE, Kutz JE, Fishman JH, McCraw LH. J Bone Joint Surg 1972; 54: 1455–8.

Similar surgery, but with less emphasis on osteophyte debridement, resulted in success for all of 36 patients followed for between 12 and 18 months postoperatively.

Use of Wolfe graft for the treatment of mucous cysts

Jamnadas-Khoda B, Agarwal R, Harper R, Page RE. J Hand Surg Eur 2009; 34: 519–21.

Forty-nine patients with 51 myxoid cysts underwent excision of the cyst on the dorsum of a finger with repair using a full-thickness graft taken from the flexor crease of the wrist. Recurrence rate rose from zero at 4 months to at least 4% longer term.

Proximal nail fold flap dissection for digital myxoid cysts – a 7 year experience

Eke U, Ahmed I, Ilchyshyn A. Dermatol Surg 2014; 40: 206–8.

Flap repair with a longer follow-up in 18 patients revealed 37% relapse rate over 5 to 84 months (median 29.7).

Ganglion of the distal interphalangeal joint (myxoid cyst): therapy by identification and repair of the leak of joint fluid

de Berker D, Lawrence C. Arch Dermatol 2001; 137: 607–10.

A study of 54 patients used methylene blue dye injected into the distal interphalangeal joint to identify the communication between the joint and the cyst. A skin flap was designed around the cyst. The communication was sutured and the flap replaced with no tissue excision. In 89% of patients the communication was identified. At 8 months, 48 patients remained cured with no visible scarring. Myxoid cysts of the toes had a higher relapse rate than those of the fingers.

Skin excision and osteophyte removal is not required in the surgical treatment of digital myxoid cysts

Lawrence C. Arch Dermatol 2005; 141: 1560–4.

The procedure in this study was limited to raising a flap overlying the distal interphalangeal joint, draining the mucoid content of the cyst, and cauterizing the underlying soft tissues on the joint. The flap was sutured back in place. Over 8 months, 24 of 26 (92%) of finger myxoid cysts remained cured. Cure rate for myxoid cysts of the toes was 33.3%.

Third-Line Therapy

• Flurandrenolide tape

D

The most likely course of action after failure of surgery is either to repeat the surgery or to modify the surgical approach to include osteophyte surgery if these were not treated in the first instance. If a CO₂ laser is available, this might also be chosen, given the good results reported in the small published series. Alternatively, sclerosant could be used, although again, multiple treatments could be anticipated.

Treatment of myxoid cyst with flurandrenolide tape

Ronchese F. R I Med J 1970; 57: 154–5.

After the failure of electrodesiccation, five patients were treated with corticosteroid tape for 2 to 3 months, and success was reported in all during a follow-up of 2 to 3 years. The rationale for this choice is where the joint appears inflamed with more marked osteoarthritis and managing the inflammation may diminish the production and efflux of synovial fluid.

Nail psoriasis

Waqas Shaikh, Joy Wan, and Adam I. Rubin

Clinical features of nail psoriasis can be divided by the site of origin within the nail unit. Signs of nail matrix psoriasis include pitting, red spots in the lunula, leukonychia, and nail plate crumbling. Signs of nail bed psoriasis include onycholysis, splinter hemorrhages, oil spots, and subungual hyperkeratosis. It is important to distinguish among these diverse manifestations of nail psoriasis, as they influence treatment selection and the response to therapy.

Management Strategy

Nail psoriasis can be challenging to diagnose and treat, but this is an important entity, causing significant emotional and physical impairments. Nails are easily visible. In professions where frequent interpersonal interactions are the norm, such as salespeople, nail psoriasis can have a detrimental impact on careers. In severe cases, the ability to manipulate small objects and accomplish routine daily tasks can be diminished significantly.

Considering the known link among nail psoriasis, enthesitis, and psoriatic arthritis, it is imperative to ask patients about current or prior history of joint pain, joint swelling, and morning stiffness lasting longer than 1 hour. A basic joint examination should also be performed. Positive findings should be further investigated with radiologic imaging and/or referral to a rheumatologist.

There are overlapping clinical features of nail psoriasis and onychomycosis, so it is important to evaluate patients for the latter possibility and remember that nail psoriasis and onychomycosis can coexist in the same patient. If present, onychomycosis should be treated first.

In cases where the diagnosis is equivocal, a nail unit biopsy may be considered for additional diagnostic information. Although nail clippings can show histologic features of psoriasis, the features seen in nail clippings alone are nonspecific. The most definitive diagnosis can be obtained from a combination of nail plate and soft tissue findings. The best anatomic area of the nail unit to biopsy corresponds to the origin of the physical signs noted. For example, if subungual hyperkeratosis is present, the nail bed would be the most appropriate location to biopsy, as the anatomic origin of this clinical sign is the nail bed.

Treatment should be tailored to the individual patient, taking into account the severity of nail disease, age, the types of clinical signs present, the extent of psoriasis on the skin, the presence or absence of concurrent psoriatic arthritis, the patient's occupation, and other comorbidities, as well as insurance coverage/regulations or lack thereof.

General nail care is of utmost importance to prevent worsening of the nail changes and to help treat existing lesions. The nail plate should be clipped back to the point of its attachment to the nail bed if possible. This prevents repetitive minor trauma. The Koebner phenomenon can affect the nails and may impede resolution, worsen existing lesions, or promote the development of new lesions on the

nails. Additionally, when subungual hyperkeratosis is prominent, patients may use instruments to clean out this material from under the nail plate. However, this type of maneuver also causes trauma to the nail and has the same consequences as described earlier.

Avoidance of excessive nail care such as filing can also diminish excess trauma. Use of gloves can be helpful during wet work, cleaning, or gardening to help protect the nails. Nail cosmetics, such as acrylic nails, may cause additional trauma in their application or removal and should be avoided.

For mild or moderate disease, topical therapies generally improve the nails. It is critical to select a therapy that will be beneficial based on the signs of nail psoriasis present. For example, with onycholysis, if the nail plate is clipped back to the point of attachment to the nail bed, topical medications can easily be applied to the specific site of psoriasis involvement (the nail bed in this case). In contrast, nail plate signs, such as nail plate crumbling and pitting, are caused by psoriatic inflammation affecting the nail matrix and will not be adequately treated by topical medications, which do not penetrate the proximal nail fold sufficiently to diffuse into the matrix. In these cases where nail matrix psoriasis is present, intralesional steroids can be effective.

Severe nail psoriasis or concomitant nail psoriasis and psoriatic arthritis would qualify for systemic therapy. If psoriatic arthritis is present, the choice of medication may be coordinated with the patient's rheumatologist and may depend on other comorbidities. Traditional systemic psoriasis medications such as acitretin and methotrexate have evidence supporting their effectiveness for nail psoriasis. However, the treatment of psoriasis has been revolutionized by the advent of biologic medications, which may have more favorable safety and efficacy profiles than the traditional systemic medications. The selection of any particular systemic medication for nail psoriasis entails a holistic view of the patient, including age, comorbidities, and insurance coverage, as well as the impact of severe nail psoriasis on quality of life.

Specific Investigations

- Record Nail Psoriasis Severity Index (NAPSI)
- Biopsy (in selected cases)

NAPSI is a commonly used tool to assess nail psoriasis severity.

Each nail is divided into four quadrants. For each quadrant, signs of nail bed psoriasis (onycholysis, splinter hemorrhages, hyperkeratosis, and oil-drop dyschromia) are identified. For each nail, a score of 0 to 4 is given for nail bed signs based on the number of quadrants involved. Similarly, nail matrix psoriasis signs (pitting, leukonychia, crumbling, and red spots in lunula) are identified in each quadrant. For each nail, a score of 0 to 4 is given for nail matrix signs based on the number of quadrants involved. The scores are added to give a total score of 0 to 8 for each nail. The maximum NAPS I is 80 for all 10 fingernails. This method can be applied to the toenails as well but is not often done.

Several other severity scoring systems for nail psoriasis also exist, but none is uniformly applied.

Nail Psoriasis Severity Index: a useful tool for evaluation of nail psoriasis

Rich P, Scher RK. J Am Acad Dermatol 2003; 49: 206–12.

First-Line Therapies

• Topical corticosteroids	A
• Topical vitamin D analogs	A
• Topical tazarotene	A
• Topical tacrolimus	B
• Intralesional triamcinolone acetonide	C

Comparison of nail lacquer clobetasol efficacy at 0.05%, 1% and 8% in nail psoriasis treatment: prospective, controlled and randomized pilot study

Nakamura RC, Abreu L, Duque-Estrada B, Tamler C, Leverone AP. An Bras Dermatol 2012; 87: 203–11.

A split-hand study of 15 patients was performed with application

of 0.05%, 1%, or 8% clobetasol nail lacquer on the left hand and base coat nail lacquer on the right hand twice a week for 16 weeks. The treated left hand group showed 51% improvement in modified NAPSI compared with baseline. No significant difference was observed across the different concentrations of clobetasol nail lacquer. No adverse effects were observed.

Calcipotriol ointment in nail psoriasis: a controlled double-blind comparison with betamethasone dipropionate and salicylic acid

Tosti A, Piraccini BM, Cameli N, Kokely F, Plozzer C, Cannata GE, et al. Br J Dermatol 1998; 139: 655–9.

This study compared twice-daily application of calcipotriol ointment (50 µg/g) to betamethasone dipropionate (64 mg/g) plus salicylic acid (0.03 g/g) ointment to the nails of 58 patients for 3 to 5 months. There was 49.2% and 51.7% reduction in fingernail subungual hyperkeratosis and 20.1% and 22.9% reduction in toenail subungual hyperkeratosis in the calcipotriol and betamethasone dipropionate plus salicylic acid groups, respectively; however, the difference between the two treatment groups was not statistically significant. Adverse effects were mild and included erythema, periungual irritation, burning, and diffuse urticaria.

In our experience, calcipotriol is well tolerated by patients. It is available as a solution, which can be helpful to treat areas of the nail that may be difficult to access.

Tazarotene 0.1% gel in the treatment of fingernail psoriasis: a double-blind, randomized, vehicle-controlled study

Scher RK, Stiller M, Zhu YI. Cutis 2001; 68: 355–8.

A study of 31 patients randomized to tazarotene 0.1% gel or vehicle gel nightly to two fingernails (one finger under occlusion and one without occlusion) for up to 24 weeks. The tazarotene group showed a significant reduction in onycholysis. Compared with the nonoccluded nails, the occluded nails had a more rapid onset of improvement in onycholysis and showed significant improvement in nail pitting. Adverse effects in the tazarotene group included skin peeling and paronychia.

In our experience, tazarotene may be irritating, and reduction of the dosage schedule can provide therapeutic improvements while decreasing the intensity of the irritation.

Tacrolimus 0.1% ointment in nail psoriasis: a randomized controlled open-label study

De Simone C, Maiorino A, Tassone F, D'Agostino M, Caldarola G. J Eur Acad Dermatol Venereol 2013; 27: 1003–6.

A single-blind, split-hand study of 21 patients treated with tacrolimus 0.1% ointment nightly for 12 weeks showed a significant 13-point reduction in NAPSI in the treated hands and a 3-point reduction in the untreated hands compared with baseline. One patient developed acute paronychia in the tacrolimus-treated hand. No other adverse effects were observed.

In our experience, topical tacrolimus is well tolerated by patients with nail psoriasis.

Treatment of nail psoriasis with intralesional triamcinolone acetonide using a needle-free jet injector: a prospective trial

Nantel-Battista M, Richer V, Marcil I, Benohanian A. J Cutan Med Surg 2014; 18: 38–42.

A pre–post comparative trial of 17 patients treated with monthly intralesional triamcinolone acetonide for 4 months led to a 46.25% decrease in target nail NAPSI compared with baseline.

The site of injection is dependent on nail pathology. Injections that target the nail matrix (at the proximal nail fold) are recommended for nail pitting, surface ridging, and nail plate thickening. Nail bed injections (often at the lateral nail fold directed medially toward the nail bed) are recommended for oil spots, onycholysis, and subungual hyperkeratosis. Nail bed injections can be uncomfortable, and topical medications may be a better choice if the medication can access the zone of involvement in the nail bed. In general, 0.1 to 0.3 mL of 2.5 to 10 mg/mL triamcinolone acetonide is injected per site. Frequencies vary from weekly to monthly to every 2 months. Potential adverse effects include injection site pain, subungual hematomas, paresthesias, skin atrophy, and terminal phalanx atrophy (“disappearing digit”). In our clinic, we offer patients a topical anesthetic or a vibratory device to help minimize discomfort with the injections. Dilution of the steroid with lidocaine may also decrease discomfort with the procedure.

Second-Line Therapies

• Acitretin	B
• Methotrexate	A
• Etanercept	B
• Adalimumab	A
• Infliximab	A
• Ustekinumab	A
• Secukinumab	A
• Apremilast	A
• Ixekizumab	A
• Golimumab	A
• Certolizumab	A

Evaluation of the efficacy of acitretin therapy for nail psoriasis

Tosti A, Ricotti C, Romanelli P, Cameli N, Piraccini BM. Arch Dermatol 2009; 145: 269–71.

Thirty-six patients with moderate to severe nail psoriasis were treated with low-dose acitretin (0.2–0.3 mg/kg/day) for 6 months in a pre–post comparative trial. There was a 41% reduction in NAPSI and 50% reduction in modified NAPSI of the target nail. Twenty-five percent showed almost complete clearance, 27% showed moderate improvement, 33% mild improvement, and 11% no improvement. Except for one patient developing severe periungual dryness and multiple pyogenic granulomas, there were no clinical or laboratory adverse effects.

Use of acitretin may be limited by patient comorbidities and in females of childbearing potential, considering its category X pregnancy designation.

A 52-week trial comparing briakinumab with methotrexate in patients with psoriasis

Reich K, Langley RG, Papp KA, Ortonne JP, Unnebrink K, Kaul M, et al. N Engl J Med 2011; 365: 1586–96.

A 52-week, double-blind, randomized trial in 317 patients with moderate to severe psoriasis comparing briakinumab and methotrexate 5 to 25 mg weekly showed a reduction in NAPSI from 4.8 to 1.2 (75% improvement) and 4.8 to 3 (38% improvement), respectively.

Briakinumab was previously under investigation for the treatment of psoriasis but is not currently available.

A 24-week randomized clinical trial investigating the efficacy and safety of two doses of etanercept in nail psoriasis

Ortonne JP, Paul C, Berardesca E, Marino V, Gallo G, Brault Y, et al. Br J Dermatol 2013; 168: 1080–7.

A 24-week, randomized, dose-comparison trial was performed in 72 patients with moderate to severe psoriasis treated with etanercept. Group 1 received etanercept 50 mg twice weekly for 12 weeks followed by once weekly for 12 weeks. Group 2 received etanercept 50 mg once weekly for 24 weeks. NAPSI score decreased from 6.0 to 1.7 (72% improvement) in group 1 and decreased from 5.8 to 1.4 (75% improvement) in group 2 at 24 weeks compared with baseline. Target

finger nail NAPSI-50 was achieved by 82.3% and 80.7% of patients in group 1 and group 2, respectively. Common adverse events were nasopharyngitis and headache.

Adalimumab for treatment of moderate to severe chronic plaque psoriasis of the hands and feet: efficacy and safety results from REACH, a randomized, placebo-controlled, double-blind trial

Leonardi C, Langley RG, Papp K, Trying SK, Wasel N, Vender R, et al. Arch Dermatol 2011; 147: 429–36.

A double-blind, placebo-controlled, randomized trial evaluated adalimumab (80 mg week 0, 40 mg week 1, and 40 mg every other week thereafter) for 16 weeks in 72 patients with moderate to severe chronic plaque psoriasis of hands/feet. At 16 weeks, there was 50% improvement in NAPSI in the adalimumab group compared with 8% improvement in the placebo group. At 28 weeks, the adalimumab group had a 54% NAPSI improvement. The most frequently reported adverse events were nasopharyngitis, headache, diarrhea, and injection site reaction.

Baseline nail disease in patients with moderate to severe psoriasis and response to treatment with infliximab during 1 year

Rich P, Griffiths CE, Reich K, Nestle FO, Scher RK, Li S, et al. J Am Acad Dermatol 2008; 58: 224–31.

In a 50-week, double-blind, randomized, placebo-controlled, crossover trial of infliximab (5 mg/kg given at weeks 0, 2, 6, and every 8 weeks thereafter) in 305 patients with nail psoriasis showed 44.7% rate of nail disease clearance and 57.2% decrease in NAPSI in the infliximab group, in contrast to 5.1% rate of nail disease clearance and 4.1% increase in NAPSI in the placebo group.

A comparative study examining infliximab, adalimumab, and etanercept showed significant improvement in NAPSI scores (95.1%, 89.5%, and 92.8%, respectively) at 48 weeks with the most rapid improvement in the infliximab group.

Ustekinumab improves nail disease in patients with moderate-to-severe psoriasis: results from PHOENIX 1

Rich P, Bourcier M, Sofen H, Fakharzadeh S, Wasfi Y, Wang Y, et al. Br J Dermatol 2014; 170: 398–407.

A double-blind, randomized, placebo-controlled, crossover trial in 545 patients with nail psoriasis treated with ustekinumab (45 mg or 90

mg at weeks 0 and 4 with a maintenance dose every 12 weeks) showed NAPSI improvement of 46.5% in the 45-mg group and 48.7% in the 90-mg group at 24 weeks.

Secukinumab improves hand, foot and nail lesions in moderate-to-severe plaque psoriasis: subanalysis of a randomized, double-blind, placebo-controlled, regimen-finding phase 2 trial

Paul C, Reich K, Gottlieb AB, Mrowietz U, Philipp S, Nakayama J, et al. *J Eur Acad Dermatol Venereol* 2014; 28: 1670–5.

Three hundred four patients with nail psoriasis from a randomized, double-blind, placebo-controlled trial were examined in this post hoc analysis. Induction regimens of secukinumab 150 mg were single dose (week 0), monthly (weeks 0, 4, and 8), or early (weeks 0, 1, 2, and 4). At 12 weeks, the composite fingernail scores improved with the early (–19.1%) and monthly (–10.6%) regimens, worsened with placebo (+14.4%), and remained stable with the single-dose regimen (–3.7%) compared with baseline.

Apremilast, an oral phosphodiesterase 4 inhibitor, in patients with difficult-to-treat nail and scalp psoriasis: results of 2 phase III randomized, controlled trials (ESTEEM 1 and ESTEEM 2)

Rich P, Gooderham M, Bachelez H, Goncalves J, Day RM, Chen R, et al. *J Am Acad Dermatol* 2016; 74: 134–42.

In a trial with 1255 patients with moderate to severe plaque psoriasis, NAPSI changed by –22.5% to –29.0% in the apremilast 30 mg twice daily group and –7.1% to +6.5% in the placebo group, compared with baseline. Common adverse events included diarrhea, nausea/vomiting, abdominal pain, weight loss, nasopharyngitis, upper respiratory tract infections, and headache. Rare serious adverse effects included depression, suicidal thoughts, and suicidal behavior.

Improvement of scalp and nail lesions with ixekizumab in a phase 2 trial in patients with chronic plaque psoriasis

Langley RG, Rich P, Menter A, Krueger G, Goldblum O, Dutronc Y, et al. *J Eur Acad Dermatol Venereol* 2015; 29: 1763–70.

In a post hoc analysis of a double-blind, placebo-controlled, randomized trial and open-label extension trial of patients with moderate to severe psoriasis, 58 patients were found to have nail psoriasis. Patients with nail psoriasis in the placebo, ixekizumab 75 mg, and ixekizumab 150 mg groups received injections at weeks 0, 2,

4, 8, 12, and 16. The placebo, ixekizumab 75 mg, and ixekizumab 150 mg groups had NAPSI reductions of 1.7%, 63.8%, and 52.6% at 20 weeks, respectively, compared with baseline. By week 48 in the open-label extension (ixekizumab 120 mg every 4 weeks) involving 51 patients, 51% of nail psoriasis patients treated with ixekizumab 120 mg showed complete nail psoriasis clearance.

Golimumab, a new human tumor necrosis factor α antibody, administered every 4 weeks as a subcutaneous injection in psoriatic arthritis: twenty-four-week efficacy and safety results of a randomized, placebo-controlled study

Kavanaugh A, McInnes I, Mease P, Krueger GG, Gladman D, Gomez-Reino J, et al. *Arthritis Rheum* 2009; 60: 976–86.

A double-blind, randomized, placebo-controlled, dose-escalation trial in 319 patients with psoriasis and psoriatic arthritis compared golimumab 50 mg every 4 weeks to golimumab 100 mg every 4 weeks. Secondary end point analysis of 287 patients with nail psoriasis showed a median percentage improvement in NAPSI at 24 weeks of 0%, 33%, and 54% in the placebo, golimumab 50 mg, and golimumab 100 mg groups, respectively. Reported adverse effects were nasopharyngitis, upper respiratory tract infections, injection site reactions, and transaminitis.

Effect of certolizumab pegol on signs and symptoms in patients with psoriatic arthritis: 24-week results of a Phase 3 double-blind randomised placebo-controlled study (RAPID-PsA)

Mease PJ, Fleischmann R, Deodhar AA, Wollenhaupt J, Khraishi M, Kielar D, et al. *Ann Rheum Dis* 2014; 73: 48–55.

A double-blind, placebo-controlled, randomized trial of certolizumab (200 mg every 2 weeks or 400 mg every 4 weeks after loading dose regimen [400 mg at week 0, 2, and 4]) was performed in 409 patients with psoriatic arthritis. Within the 79.3% of patients with baseline nail disease, there was a change in mean NAPSI of –1.1 (32% decrease), –1.6 (52% decrease), and –2.0 (59% decrease) in the placebo, certolizumab 200 mg, and certolizumab 400 mg groups after 24 weeks, respectively. Common adverse effects were injection site reactions, diarrhea, headache, nasopharyngitis, upper respiratory tract infections, and transaminitis.

Third-Line Therapies

• Topical 5-fluorouracil	A
• Topical Psoralen and ultraviolet A (PUVA)	D
• Pulsed dye laser (PDL)	A
• Excimer laser	B
• Photodynamic therapy (PDT)	B
• Lindioil	B
• Ciclosporin	B
• Anthralin	D
• Intense pulsed light (IPL)	D
• Leflunomide	D
• Tofacitinib	A

Dystrophic psoriatic fingernails treated with 1% 5-fluorouracil in a nail penetration-enhancing vehicle: a double-blind study

De Jong EM, Menke HE, van Praag MC, van De Kerkhof PC.

Dermatology 1999; 199: 313–8.

In a split-hand study of 57 patients with psoriatic fingernails, 1% topical 5-fluorouracil in a urea and propylene glycol vehicle (Belanyx lotion) and Belanyx lotion alone both led to 30% to 40% improvement in the total nail area severity (NAS) scores of a target nail and to improved patient- and investigator-reported outcomes after 12 weeks. No significant difference was observed between the two treatments, however.

Topical 5-fluorouracil can worsen onycholysis and should thus be used with caution in nail psoriasis patients who have onycholysis as the most prominent sign.

Local PUVA treatment for nail psoriasis

Handfield-Jones SE, Boyle J, Harman RR. *Br J Dermatol* 1987; 116: 280–1.

In a case series of five patients, 1% 8-methoxypsoralen (Meladine) solution was applied from the proximal nail fold up to the terminal phalanx of affected fingernails followed by 0.5 J/cm² increasing up to a max of 2 J/cm² of ultraviolet A (UVA) two to three times a week. Two patients achieved sustained clearance for 4 to 8 months, two patients improved significantly, and one patient did not have sustained improvement. Onycholysis appeared to respond better to topical PUVA than did nail pits.

The effect of different pulse durations in the treatment of nail psoriasis with 595-nm pulsed dye laser: a randomized, double-blind, inpatient left-to-right study

Treewittayapoom C, Singvahanont P, Chanprapaph K, Haneke E. *J Am Acad Dermatol* 2012; 66: 807–12.

Twenty patients were treated monthly with 6-ms pulse duration and 9 J/cm² PDL settings on one hand and 0.45-ms pulse duration and 6 J/cm² PDL settings on the other for 6 months. NAPI improved significantly in both groups (roughly 40% decrease) within the first 3 months, but there was no significant difference between the two pulse duration groups. Participants reported greater pain with the longer pulse duration, and transient petechiae and hyperpigmentation were observed in both groups.

Single blinded left-to-right comparison study of excimer laser versus pulsed dye laser for the treatment of nail psoriasis

Al-Mutairi N, Noor T, Al-Haddad A. *Dermatol Ther* 2014; 4: 197–205.

Forty-two patients with psoriatic nail disease were treated with twice-weekly excimer laser on the right hand and monthly PDL on the left hand for up to 12 weeks in this unblinded study. The mean NAPI scores decreased significantly in both treatment groups, but improvement was significantly greater with PDL (NAPI decreased from 29.5–3.2 [89% reduction]) than excimer laser (NAPI decreased from 29.8–16.3 [45% reduction]). Subungual hyperkeratosis and onycholysis were most responsive to laser treatment, whereas nail pitting was least responsive.

Pulsed dye laser vs. photodynamic therapy in the treatment of

refractory nail psoriasis: a comparative pilot study

Fernandez-Guarino M, Harto A, Sanchez-Ronco M, Garcia-Morales I, Jaen P. J Eur Acad Dermatol Venereol 2009; 23: 891–5.

In an unblinded, inpatient, split-hand study, 14 patients received PDT (methyl-aminolevulinic acid [MAL] with PDL) on one hand and PDL alone on the other hand monthly for 6 months. Both treatments resulted in improvements in NAPSI, but there was no significant difference between PDT and PDL.

Although the results suggest a lack of benefit with topical MAL, we cannot make any definitive conclusions about the efficacy of PDT for nail psoriasis based on this lone study.

A Chinese herb, *Indigo naturalis*, extracted in oil (Lindioil) used topically to treat psoriatic nails: a randomized clinical trial

Lin YK, Chang YC, Hui RC, See LC, Chang CJ, Yang CH, et al. JAMA Dermatol 2015; 151: 672–4.

In an investigator-blinded, split-hand study of Lindioil versus topical calcipotriol solution in 33 patients, significantly greater improvements in the single-hand NAPSI scores were seen in Lindioil-treated nails (51.3% improvement) compared with calcipotriol-treated nails (27.1% improvement) after 24 weeks. Two patients experienced irritation from Lindioil.

Evaluation of the efficacy of methotrexate and cyclosporine therapies on psoriatic nails: a one-blind, randomized study

Gumusel M, Ozdemir M, Mevlitoglu I, Bodur S. J Eur Acad Dermatol Venereol 2011; 25: 1080–4.

In an investigator-blinded, randomized trial, 34 patients received subcutaneous methotrexate (15 mg weekly for first 3 months, then 10 mg weekly for the second 3 months) or ciclosporin (5 mg/kg/day for the first 3 months, then 2.5–3.5 mg/kg/day for the second 3 months), which led to a moderate reduction in NAPSI scores by 43% and 37%, respectively, after 6 months. There was no significant difference between the two treatment groups. Methotrexate was associated with statistically significant improvements in nail matrix findings, whereas ciclosporin was associated with statistically significant improvements in nail bed findings.

Topical anthralin therapy for refractory nail psoriasis

Yamamoto T, Katayama I, Nishioka K. J Dermatol 1998; 25: 231–3.

In the comparative prepost study of 20 patients who applied 0.4% to 2.0% anthralin in petrolatum daily for 5 months, 12 (60%) patients had greater than 50% improvement of their nails, and 4 (20%) patients had no response. Anthralin worked most effectively for onycholysis and thickened nails and variably for pitting, whereas transverse or longitudinal lines did not respond. The main side effect was reversible pigmentation of the nail plate.

Novel treatment of nail psoriasis using the intense pulsed light: a one-year follow-up study

Tawfik AA. *Dermatol Surg* 2014; 40: 763–8.

In the comparative prepost study, 20 patients with fingernail and toenail psoriasis were treated with IPL every 2 weeks until no further improvement or for a maximum of 6 months. After a mean of 8.6 treatments, significant improvements were observed in NAPSI scores, with 32.2% of patients improving on the nail matrix NAPSI and 71.2% of patients improving on the nail bed NAPSI. Nail disease relapsed in three patients after 6 months after treatment.

Leflunomide in psoriatic arthritis: results from a large European prospective observational study

Behrens F, Finkenwirth C, Pavelka K, Stolfa J, Sipek-Dolnicar A, Thaci D, et al. *Arthritis Care Res* 2013; 65: 464–70.

A subgroup analysis of nail psoriasis was performed within a prospective, 24-week observational study of 511 patients receiving leflunomide for treatment of psoriatic arthritis. Approximately 32% of patients with psoriatic nail lesions at baseline had significant improvement in their nails. In the overall study, 12% of patients experienced adverse effects, most frequently diarrhea, alopecia, hypertension, and pruritus. Three instances of serious drug reactions (transaminitis and hypertensive crisis) were observed.

Tofacitinib, an oral Janus kinase inhibitor, for the treatment of chronic plaque psoriasis: results from two randomized, placebo-controlled, phase III trials

Papp KA, Menter MA, Abe M, Elewski B, Feldman SR, Gottlieb AB, et al. *Br J Dermatol* 2015; 173: 949–61.

In subgroup analyses significant dose-dependent improvements in NAPSI were observed at week 16. NAPSI improved by a mean of 14% to 22% among the 408 patients with nail psoriasis who received

tofacitinib 5 mg twice daily and by 26% to 42% among the 404 patients who received tofacitinib 10 mg twice daily. Although overall rates of adverse events were similar across treatment groups, there were 12 cases of herpes zoster in the tofacitinib groups in contrast to none in the placebo groups.

Necrobiosis lipoidica

Nicole Yi Zhen Chiang, and Ian Coulson

Necrobiosis lipoidica (NL) is a chronic cutaneous granulomatous condition with degenerative connective tissue changes. It is only seen in 1 in 300 diabetics but may be unassociated with glucose intolerance. NL may rarely be complicated by ulceration and

squamous cell carcinoma.

Management Strategy

Smoking cessation and avoiding trauma to the affected shins are key factors to avoid transformation from an unsightly plaque into a painful, recalcitrant ulcer. The progression of new lesions may be halted by *intralesional or occluded potent topical corticosteroids* applied to the margins of the lesions. Once atrophy has developed, there is little that will reverse this, although *topical retinoids* may be tried.

Telangiectasia is often marked and has been treated with *pulsed dye laser*. Extensive lesions may justify trials of *nicotinamide or prednisolone*. Antiplatelet therapy in the form of *aspirin or dipyridamole* has its enthusiasts, though responses are inconclusive. Phototherapy such as *topical psoralen and Ultraviolet VA (PUVA) and UVA -1*, as well as *photodynamic therapy*, have received recent interest and may arrest progression and improve the appearance. A variety of systemic antiinflammatory and immunosuppressive agents have been tried with some success, including *mycophenolate mofetil, fumaric acid esters, ciclosporin, antimalarials, thalidomide, and pentoxifylline*. *Infliximab and etanercept* have also been proposed.

The chronically ulcerated lesion is a challenge; antibiotics deal with secondary infection, appropriate dressings may be required, and growth factors such as *becaplermin and granulocyte–macrophage colony-stimulating factor (GM-CSF)* may accelerate healing. Because diabetics may have coexisting large vessel atherosclerosis that may contribute to ulceration, noninvasive arterial studies or angiography needs to be considered if clinically indicated.

Excision and grafting may transform the patient's quality of life and improve cosmesis. Work with the diabetologist to optimize diabetic control.

Specific Investigations

- Two-hour postprandial glucose
- Skin biopsy
- Consider angiography or venous circulation studies
- Consider a biopsy to exclude sarcoidosis, which may mimic NL, or if clinical features suggest, the rare development of squamous

- cell carcinoma
- Consider thyroid function tests

Squamous cell carcinoma arising in an area of long-standing necrobiosis lipoidica

Lim C, Tschuchnigg M, Lim J. *J Cutan Pathol* 2006; 33: 581–3.

Case report of a squamous cell carcinoma arising de novo in an area of NL.

Carcinoma cuniculatum arising in necrobiosis lipoidica

Porneuf M, Monpoint S, Barnéon G, Alirezai M, Guillot B, Guilhou JJ. *Ann Dermatol Venereol* 1991; 118: 461–4.

Although rare, squamous cell carcinomas may complicate any condition in which papillary dermal scarring is appreciable.

Unilateral necrobiosis lipoidica of the ischemic limb – a case report

Naschitz JE, Fields M, Isseroff H, Wolffson V, Yeshurun D. *Angiology* 2003; 54: 239–42.

A possible ischemic pathogenesis of NL emerges from a case of unilateral large vessel arteriosclerotic ischemia with ipsilateral NL.

The author has experience of a severely ulcerated area of NL that only started to heal after the disobliteration of severe femoropopliteal atheroma.

Updated results of 100 patients on clinical features and therapeutic options in necrobiosis lipoidica in a retrospective multicenter study

Erfurt-Berge C, Dissemond J, Schwede K, Seitz AT, Al Ghazal P, Wollina U, et al. *Eur J Dermatol* 2015 25:595–601.

This multicenter retrospective study included 100 patients with NL lesions on the lower leg. Thyroid disorders were found in 15% of all cases.

First-Line Therapies

• Stop smoking and optimize diabetic control	C
• Intralesional or topical corticosteroids under occlusion	D

Necrobiosis lipoidica diabeticorum: association with background retinopathy, smoking, and proteinuria. A case controlled study

Kelly WF, Nicholas J, Adams J, Mahmood R. Diabet Med 1993; 10: 725–8.

Stop smoking and control diabetes mellitus with vigilance. Fifteen diabetics with NL were each matched with five control subjects with diabetes mellitus. Background retinopathy, proteinuria, and smoking were all more common with NL. No differences were noted between those with NL and controls in the prevalence of vascular disease and neuropathy. Glycosylated hemoglobin concentrations were higher in patients with NL.

Granuloma annulare and necrobiosis lipoidica treated by jet injector

Sparrow G, Abell E. Br J Dermatol 1975; 93: 85–9.

Three of five cases of NL underwent complete resolution, and one had partial improvement with 5 mg/mL triamcinolone injection to the edges of lesions. No serious complications of this type of treatment were observed.

Treatment of psoriasis and other dermatoses with a single application of a corticosteroid left under a hydrocolloid occlusive dressing for a week

Juhlin L. Acta Dermatol Venereol 1989; 69: 355–7.

A 0.1% betamethasone alcoholic lotion under a hydrocolloid dressing was an effective, well-tolerated treatment, and three applications only were required.

Second-Line Therapies

• Systemic corticosteroids	D
• Aspirin and dipyridamole	C
• Pentoxifylline	E
• Nicotinamide	D
• Clofazimine	D
• Topical PUVA	D
• Topical tacrolimus	E

Necrobiosis lipoidica: treatment with systemic corticosteroids

Petzelbauer P, Wolff K, Tappeiner G. Br J Dermatol 1992; 126: 542–5.

Oral methylprednisolone was given to six patients with nonulcerating NL for 5 weeks; in all there was cessation of disease activity during the 7-month follow-up period. Initial dosage was 1 mg/kg daily for 1 week, then 40 mg daily for 4 weeks, followed by tapering and termination in 2 weeks. All patients, including the diabetics, tolerated the treatment well. There was no improvement in atrophy. Benefit was maintained at the end of the 7-month follow-up period.

Careful monitoring of blood glucose is mandatory in all diabetic patients with NL treated with systemic corticosteroids.

Pentoxifylline: an effective therapy for necrobiosis lipoidica

Wee E, Kelly R. Australas J Dermatol 2015 Nov 12 [Epub ahead of print].

Three cases of biopsy-proven NL were treated with pentoxifylline 400 mg three times daily. Patient 1 and 2 had early-stage NL, presenting with indurated, red-brown plaques. Pentoxifylline

reversed the inflammation and induration completely after 7 and 12 months, respectively. No recurrence in activity was seen in patient 1 after 12 months. In patient 3, pentoxifylline was effective in reversing ulceration completely after 10 months of treatment. Some areas of atrophy remained in all patients. None of the patients reported significant side effects.

Healing of necrobiotic ulcers with antiplatelet therapy. Correlation with plasma thromboxane levels

Heng MC, Song MK, Heng MK. *Int J Dermatol* 1989; 28: 195–7.

NL in diabetics has been considered a cutaneous manifestation of diabetic microangiopathy. Seven diabetic patients with necrobiotic ulcers of recent onset that healed after administration of 80 mg/day of acetylsalicylic acid and 75 mg three times daily of dipyridamole had elevated thromboxane levels. Healing was associated with depression of the elevated thromboxane levels in all seven patients.

Treatment of necrobiosis lipoidica with low-dose acetylsalicylic acid. A randomized double-blind trial

Beck HI, Bjerring P, Rasmussen I, Zachariae H, Stenbjerg S. *Acta Dermatol Venereol* 1985; 65: 230–4.

No response was seen with the use of 40 mg acetylsalicylic acid daily for 24 weeks, despite documented platelet aggregation inhibition.

Necrobiosis lipoidica: a case with histopathological findings revealed asteroid bodies and was successfully treated with dipyridamole plus intralesional triamcinolone

Jiquan S, Khalaf AT, Jiquan T, Xiaoming L. *J Dermatolog Treat* 2008; 19: 54–7.

A 48-year-old woman with more than 2 years' history of NL plaques on her right leg responded to 25 mg three times daily of dipyridamole plus intralesional triamcinolone. After 4 weeks of therapy, she developed mild dizziness, and the dose was reduced to twice daily. The NL lesions healed completely after 2 months.

High dose nicotinamide in the treatment of necrobiosis lipoidica

Handfield-Jones S, Jones S, Peachey R. *Br J Dermatol* 1988; 118: 693–6.

An open study of high-dose nicotinamide (1.5 grams a day) in the treatment of 15 patients with NL. Of 13 patients who remained on

treatment for more than 1 month, 8 improved. A reduction in pain, soreness, and erythema, and the healing of ulcers if present, was noted. There were no significant side effects, particularly with respect to diabetic control. Lesions tended to relapse if treatment was stopped.

Clofazimine – therapeutic alternative in necrobiosis lipoidica and granuloma annulare

Mensing H. Int J Dermatol 1989; 28: 195–7.

Ten patients with NL were treated with clofazimine 200 mg orally daily. Six of 10 patients responded; 3 of the responders achieved complete remission of the dermatosis. All the patients treated had reddening of the skin, but this was reversible after the end of therapy, as were the other side effects (i.e., diarrhea and dryness of the skin).

Topical PUVA treatment for necrobiosis lipoidica

McKenna DB, Cooper EJ, Tidman MJ. Br J Dermatol 2000; 143: 71.

Four of eight patients with NL responded favorably to topical PUVA using a 0.15% methoxsalen emulsion, with weekly treatments, starting with 0.5 J/cm² with 20% incremental increases until erythema developed at the edge of the lesions. The mean number of treatments administered was 39.

Successful treatment of chronic ulcerated necrobiosis lipoidica with 0.1% topical tacrolimus ointment

Clayton T, Harrison P. Br J Dermatol 2005; 152: 581–2.

A case report of ulcerated NL that healed successfully with 0.1% tacrolimus ointment applied twice daily for 1 month.

Third-Line Therapies

• Topical retinoids	E
• Ciclosporin	E
• Heparin	E
• Antimalarials	E
• Mycophenolate mofetil	E
Table Continued	

• Colchicine	E
• Tumor necrosis factor (TNF) antagonists	E
• Fumaric acid esters	D
• Promogran for ulceration	E
• GM-CSF for ulceration	D
• Becaplermin for ulceration	E
• Photodynamic therapy	D
• Pulsed dye laser for telangiectasia	E
• Surgery for ulceration	E
• Thalidomide	E
• Intravenous immunoglobulins and methylprednisolone	E
• Ultraviolet A1 phototherapy	D
• Platelet-rich plasma	D

Necrobiosis lipoidica treated with topical tretinoin

Heymann WR. *Cutis* 1996; 58: 53–4.

A case is presented in which atrophy was diminished by the application of topical tretinoin.

Persistent ulcerated necrobiosis lipoidica responding to treatment with cyclosporin

Darvay A, Acland KM, Russell-Jones R. *Br J Dermatol* 1999; 141: 725–7.

In two patients with severely ulcerated NL the ulceration healed completely after 4 months of cyclosporin therapy, and both patients have remained free of ulceration since. Effective doses were between 3 and 5 mg/kg daily. Three other reports of the effective use of cyclosporin therapy in ulcerated NL now exist.

Minidose heparin therapy for vasculitis of atrophie blanche

Jetton RL, Lazarus GS. *J Am Acad Dermatol* 1983; 8: 23–6.

The authors speculate that subcutaneous heparin 5000 IU twice daily may help NL because it helped the vasculitis associated with atrophie blanche. A subsequent letter informs that perilesional low-dose heparin has been successfully used in NL by Russian dermatologists.

Necrobiosis lipoidica diabetorum treated with chloroquine

Nguyen K, Washenik K, Shupack J. *J Am Acad Dermatol* 2002; 46(Suppl Case Reports): S34–6.

Single successful report using oral chloroquine.

Significant improvement in ulcerative necrobiosis lipoidica with hydroxychloroquine

Kavala M, Sudogan S, Zindanci I, Kocaturk E, Can B, Turkoglu Z, et al. *Int J Dermatol* 2010; 49: 467–9.

A 62-year-old woman with type 2 diabetes mellitus and ulcerative NL on both shins achieved almost complete clearance of ulcerations after taking oral hydroxychloroquine, 200 mg twice daily, for 10 weeks.

Ulcerative necrobiosis lipoidica responsive to colchicine

Schofield C, Sladden MJ. *Australas J Dermatol* 2012; 53: e54–7.

Single report of 10 years of bilateral ulcerative NL achieved complete resolution of ulcers after 2 months of colchicine 500 µg twice

daily.

Successful treatment of ulcerated necrobiosis lipoidica with mycophenolate mofetil

Reinhard G, Lohmann F, Uerlich M, Bauer R, Bieber T. *Acta Dermatol Venereol* 2000; 80: 312–3.

A 61-year-old woman with NL for over 30 years was started on mycophenolate mofetil 0.5 g twice daily, and the lesions regressed within 4 weeks. The dose was reduced to 0.5 g over the next 4 months and then stopped. Within 14 days of stopping mycophenolate mofetil the ulceration recurred.

Photodynamic therapy of necrobiosis lipoidica – a multicenter study of 18 patients

Berking C, Hegyi J, Arenberger P, Ruzicka T, Jemec GB. *Dermatology* 2009; 218: 136–9.

A retrospective study of 18 patients with NL who were treated with photodynamic therapy (PDT) using methyl aminolevulinate or 5-aminolevulinic acid as topically applied photosensitizers. Complete response was seen in 1/18 patients after 9 PDT cycles and partial response in 6/18 patients (2–14 PDT cycles), giving an overall response rate of 39% (7/18).

Photodynamic therapy for necrobiosis lipoidica is an unpredictable option: three cases with different results

Truchuelo T, Alcántara J, Fernandez-Guarino M, Pérez B, Jaén P. *Int J Dermatol* 2013; 52: 1567–1624.

Three patients were treated with methyl aminolevulinic (MAL) acid cream (Metvix) under occlusion for 3 hours, followed by irradiation with red light (630 nm, 37 J/cm², 7.5 min). The intervals between treatment ranged from 1 to 3 months (patient 1: two sessions, patient 2: one session, and patient 3: three sessions). Patient 1 and 2 were nonresponders. Patient 3 experienced great improvement after the second session. Pain during irradiation was the most common side effect.

Effectiveness of platelet-rich plasma in healing necrobiosis lipoidica diabeticorum ulcers

Motolese A, Vignati F, Antelmi A, Saturni V. *Clin Exp Dermatol* 2015; 40: 39–41.

Fifteen patients with recalcitrant NL on the legs were treated with homologous platelet-rich plasma. All patients responded with a mean reduction in wound size of 79% after 84 to 126 days without any adverse effects.

Successful treatment of ulcerative necrobiosis lipoidica diabeticorum with intravenous immunoglobulin in a patient with common variable immunodeficiency

Barouti N, Qian Cao A, Ferrara D, Prins C. JAMA Dermatol 2013; 149: 879–81.

A 63-year-old female with recurrent ear, nose, and throat infections and 7 years of ulcerating NL lesions was found to have common variable immunodeficiency (CVID). The patient was treated with intravenous immunoglobulin (0.4 g/kg/d) for 5 consecutive days. Three weeks after this single cycle, all ulcerations healed completely with no recurrence after 2 years.

Intralesional infliximab in noninfectious cutaneous granulomas: three cases of necrobiosis lipoidica

Barde C, Laffitte E, Campanelli A, Saurat JH, Thielen AM. Dermatology 2011; 222: 212–6.

Three patients with NL had three cycles of three weekly injections of intralesional infliximab with a 1-week treatment interruption between each cycle. Two patients experienced almost complete remission for up to 18 months. The third patient showed partial improvement. No serious side effects were noticed, apart from pain at injection sites.

Treatment of refractory ulcerative necrobiosis lipoidica diabeticorum with infliximab: report of a case

Hu SW, Bevona C, Winterfield L, Qureshi AA, Li VW. Arch Dermatol 2009; 145: 437–9.

An 84-year-old woman with a 3-year history of ulcerative NL on the right leg responded to five infusions of intravenous infliximab (5 mg/kg) at weeks 0, 2, 6, 12, and 21. Complete wound healing was achieved at week 6 of infliximab therapy, with excellent cosmesis. The patient experienced no adverse effects from infliximab and no recurrence for more than 1 year.

Treatment of necrobiosis lipoidica with etanercept and

adalimumab

Zhang KS, Quan LT, Hsu S. *Dermatol Online J* 2009; 15: 12.

A 29-year-old with noninsulin-dependent diabetes and more than 9 years' history of NL on her legs and trunk received subcutaneous etanercept 50-mg injections twice weekly for 3 months and then weekly after that. She achieved significant improvement and complete pain resolution by 4 months. Due to insurance reasons, the patient was switched to subcutaneous adalimumab (40 mg) injections for 3 months, which did not result in any improvement. Six months after switching back to etanercept, the patient reported progressive improvement in the NL lesions. No significant side effects were reported apart from tiredness.

Treatment of necrobiosis lipoidica with the tumor necrosis factor antagonist etanercept

Zeichner JA, Stern DW, Lebwohl M. *J Am Acad Dermatol* 2006; 54: S120–1.

A 35-year-old woman with type 1 diabetes and NL plaque on her right shin was started on weekly intralesional etanercept (25 mg) injections into the dermis at 1-cm intervals throughout the surface area of the lesion. Initial improvement was observed by the first month of treatment, and the lesion continued to resolve over the next 8 months. The patient experienced no side effects from etanercept.

Fumaric acid esters in necrobiosis lipoidica: results of a prospective noncontrolled study

Kreuter A, Knierim C, Stücker M, Pawlak F, Rotterdam S, Altmeyer P, et al. *Br J Dermatol* 2005; 153: 802–7.

Eighteen patients with NL were given the standard Fumaderm regimen as used in psoriasis for at least 6 months. Three discontinued therapy, but the rest gained significant clinical, ultrasonographic, and histologic improvement.

The management of hard-to-heal necrobiosis with Promo-gran

Omugha N, Jones AM. *Br J Nurs* 2003; 15: S14–20.

A single case study with nonhealing ulcerated NL of 3 years' duration. Treatment with a new protease-modulating matrix (freeze-dried matrix composed of collagen and oxidized regenerated cellulose) resulted in complete healing of the ulcer after 8 weeks, where other dressing regimens had failed to effect healing over a

period of 2.5 years.

Healing of chronic leg ulcers in diabetic necrobiosis lipoidica with local granulocyte–macrophage colony-stimulating factor treatment

Remes K, Ronnema T. J Diabetes Complications 1999; 13: 115–8.

Topical recombinant human GM-CSF healed two patients with ulcerated NL within 10 weeks. A reduction in the size of the ulcers was already evident after the first topical applications. The ulcers have remained healed for more than 3 years.

Becaplermin and necrobiosis lipoidicum diabeticorum: results of a case control pilot study

Stephens E, Robinson JA, Gottlieb PA. J Diabetes Complications 2001; 15: 55–6.

Five patients with type 1 diabetes mellitus and NL were treated with topical becaplermin gel (recombinant platelet-derived growth factor). The index patient had ulcerated NL, and this healed. Three of the five patients with nonulcerated NL reported a subjective improvement in sensation and lightening of color of the lesions. However, serial photographs and measurements over the 5-month treatment period showed no significant change in the size of the treated areas.

The surgical treatment of necrobiosis lipoidica diabeticorum

Dubin BJ, Kaplan EN. Plast Reconstruct Surg 1977; 60: 421–8.

Seven cases treated by excision of the lesions down to the deep fascia, ligation of the associated perforating blood vessels, and the use of split-skin grafts to cover the defects. There were no recurrences.

Thalidomide for the treatment of refractory necrobiosis lipoidica

Kukreja T, Peterson J. Arch Dermatol 2006; 142: 20–2.

A 51-year-old woman was treated successfully with a dose of thalidomide 150 mg daily, tapering to 50 mg twice weekly. A response was seen after 4 months and maintained after 2 years.

Treatment of ulcerated necrobiosis lipoidica with intravenous immunoglobulin and methylprednisolone

Batchelor JM, Todd PM. J Drugs Dermatol 2012; 11: 256–9.

The authors report a case of a female patient with recalcitrant

ulcerated NL that was resistant to several systemic agents but who initially responded to intravenous immunoglobulin. However, this became less effective over time, but a course of intravenous methylprednisolone led to regression.

UVA1 phototherapy for treatment of necrobiosis lipoidica

Beattie PE, Dawe RS, Ibbotson SH, Ferguson J. Clin Exp Dermatol 2006; 31: 235–8.

Six patients with NL were treated with UVA1 irradiation. The minimum erythema dose was determined at 24 h, and 50% of this dose was used as a starting dose. Treatment was given three to five times weekly with increments of 20% at each visit. NL resolved completely in one patient after 29 exposures. Two subjects obtained moderate improvement after 15 and 24 exposures, whereas two had only minimal improvement after 15 and 51 exposures. The remaining patient had no improvement after 16 treatments.

Necrolytic acral erythema

Courtney Rubin, and Carrie Kovarik

Necrolytic acral erythema (NAE) is characterized as sharply demarcated, erythematous to violaceous, hyperpigmented, hyperkeratotic plaques with variable scale and occasional erosions, surrounded by a rim of erythema. The lesions of NAE tend to affect the dorsal hands and feet (especially the great toe) but have also been reported to extend to the legs and trunk. The head, neck, palms, soles, nail plate, nail bed, and mucous membranes are typically spared, though exceptions have been noted. Less commonly, NAE may present with acute blistering lesions.

Hepatitis C virus (HCV) infection is one of the most common bloodborne infections globally, with approximately 3% of the world's population affected. Although HCV infection primarily affects the liver, it has also been associated with several mucocutaneous manifestations, including leukocytoclastic vasculitis,

cryoglobulinemia, lichen planus, porphyria cutanea tarda, polyarteritis nodosa, and generalized pruritus. NAE is another distinct cutaneous manifestation of HCV infection that was first described in 1996 in Egypt in seven patients with chronic HCV infection.

Management Strategy

Some have categorized the evolution of NAE into three distinct stages. The initial stage consists of a small (2–3 mm) erythematous papule that grows in surface area and thickness to become covered in scale. The center of the papule may become dusky or develop an erosion. The fully developed stage consists of increasing surface area and confluence of the initial stage lesions, leading to sharply demarcated erythematous lichenified plaques with overlying scale. Thin crust, vesicles, pustules, and weeping may also be seen in this stage. The late stage is characterized by thinning and hyperpigmentation of previously developed lesions, followed by spontaneous relapse and remission. The lesions of NAE are often locally pruritic, though in some cases the pruritus can be generalized. Other patients have complained that the lesions cause aching or burning pain.

Although the exact pathogenesis of NAE is not known, infection with hepatitis C seems to have an essential role in the development of it. The lack of NAE lesions in patients with other cirrhotic conditions such as alcoholic hepatitis or hepatitis B infection excludes chronic liver damage as the sole cause. Attempts to identify hepatitis C viral particles or RNA in NAE biopsies using electron microscopy and reverse transcription polymerase chain reaction (RT-PCR) have not been successful. Reduced amino acid levels, elevated glucagon levels, reduced fatty acid levels, reduced serum zinc, and reduced epidermal zinc have all been implicated in NAE and may be related to HCV-induced metabolic alterations. Zinc deficiency especially has been suggested as a pathogenic factor given the responsiveness of NAE to oral zinc sulfate. Although many patients with NAE who respond to oral zinc have normal zinc levels, some have postulated that cutaneous zinc levels may be low in these patients. The role of zinc in the pathogenesis of NAE remains unclear. Because zinc is believed to be antiapoptotic, some have postulated that its deficiency may lead to epidermal necrolysis. Zinc deficiency may also impair the transport of

essential nutrients like vitamin A to the epidermis. Because not all patients with NAE are responsive to oral zinc supplementation, it is likely that the etiology of NAE is multifactorial.

In one study, 87% of patients diagnosed with NAE were unaware of their underlying HCV infection.

Early NAE may present with vesicular lesions on the dorsal hands or feet that may be confused with acute eczematous reactions, contact dermatitis, or stasis changes when it is limited to the feet and/or legs. Chronic NAE may mimic lichen simplex chronicus. The necrolytic erythemas include necrolytic migratory erythema, acrodermatitis enteropathica, pellagra, and NAE. Although these entities may all share some clinical and histologic features, they can be distinguished based on cutaneous distribution and underlying biochemical abnormalities. Necrolytic migratory erythema presents with elevated glucagon levels, whereas acrodermatitis enteropathica presents with depressed zinc levels, and pellagra is associated with niacin deficiency. NAE may also be distinguished based on its association with HCV and acral distribution.

On histology, NAE demonstrates psoriasiform hyperplasia, acanthosis, papillomatosis, and parakeratosis. Vascular ectasia can be seen within the dermal papillae, along with pigment incontinence. A superficial, patchy, dermal, perivascular lymphocytic and neutrophilic infiltrate with extension into the epidermis is often seen, along with necrotic keratinocytes in the superficial epidermis. In the absence of necrotic keratinocytes, NAE can be easily confused with psoriasis histologically. Because NAE lacks pathognomonic histology, a high index of suspicion and clinical-pathologic correlation is required for diagnosis.

Specific Investigations

- Liver function tests
- Serology for hepatitis C
- Skin biopsy

In patients who may have NAE, a hepatitis panel and liver function tests can help to clarify the diagnosis. Other tests that may distinguish NAE from entities in the differential diagnosis include serum albumin, total protein, amino acids, zinc, biotin, and glucagon levels.

A cutaneous marker of viral hepatitis C

El Darouti M, Abu el Ela M. Int J Dermatol 1996; 35: 252–6.

A cutaneous sign of hepatitis C virus infection

Abdallah MA, Ghazzi MY, Monib HA, Hafez AM, Hiatt KM, Smoller BR, et al. J Am Acad Dermatol 2005; 53: 247–51.

Many patients diagnosed with NAE have historically been from Egypt, where the high burden of HCV infection has affected 15% to 20% of the population. The increased prevalence of NAE in Egypt may also be related to HCV genotype 4, which is endemic there, or a genetic predisposition in the population or environmental cofactor. In the United States the prevalence of NAE among patients with chronic HCV infection appears to be low, around 1.7%.

Low prevalence of necrolytic acral erythema in patients with chronic hepatitis C virus infection

Raphael B, Dorey-Stein ZL, Lott J, Amorosa V, Lo Re V, Kovarik C. J Am Acad Dermatol 2012; 67: 962–8.

Most patients in the United States with NAE are African American, and there does not appear to be a gender predilection. The vast majority of NAE has been observed in patients with HCV infection. However, several cases of seronegative NAE have been reported.

First-Line Treatments

• Zinc sulfate	C
• Treatment of underlying hepatitis C	C

Necrolytic acral erythema as a cutaneous marker of hepatitis C: report of two cases and review

Tabibian JH, Gerstenblith MR, Tedford RJ, Junkins-Hopkins JM, Abuav R. Dig Dis Sci 2010; 55: 2735–43.

Necrolytic acral erythema: a review of the literature

Geria AN, Holcomb KZ, Scheinfeld NS. Cutis 2009; 83: 309–14.

The cost, safety, and previous success of oral zinc supplementation in treating NAE make it first-line therapy. A response to oral zinc supplementation is usually observed within several weeks. The response to oral zinc seems to be dose dependent, with less improvement when a lower dose, such as 60 mg per day, is used. Although some patients successfully treated with oral zinc demonstrate low zinc levels, many are responsive to oral zinc supplementation despite normal zinc levels. Remission of lesions after a combination of oral zinc and intralesional injections of interferon alfa-2b has also been reported, suggesting that treatment with oral zinc may be enhanced by interferon.

Thus far, oral zinc supplementation with 220 mg oral zinc sulfate twice daily seems to be the most effective treatment for NAE with the fewest side effects. Many have reported improvement in and remission of NAE with long-term oral zinc supplementation. Successful treatment of NAE often leaves behind postinflammatory pigmentation with complete resolution of symptoms. The mechanism by which oral zinc treats NAE is not yet understood. It is possible that patients with HCV have metabolic derangements that lead to low zinc levels or that these patients have low cutaneous zinc levels even in the setting of normal plasma zinc. Zinc may also have an antiinflammatory, antiviral, and immune-stimulatory effect. Those patients being treated with long-term zinc supplementation should have serum copper levels monitored, as zinc therapy may alter copper bioavailability.

Second-Line Therapies

• Narrowband ultraviolet B (UVB) phototherapy	E
• Topical tacrolimus	E

Necrolytic acral erythema: successful treatment with topical tacrolimus ointment

Manzur A, Siddiqui AH. Int J Dermatol 2008; 47: 1073–5.

Patients have been reported to have modest improvement of NAE after narrowband UVB therapy, and one patient completely cleared

and maintained remission after a liver transplant. Improvement in NAE has also been reported after treatment of the underlying HCV with interferon alpha, with or without ribavirin. However, NAE may relapse after the interferon treatment is discontinued. There is one report of complete resolution of NAE after application of 0.1% topical tacrolimus ointment for 4 weeks. NAE generally does not respond to topical corticosteroids or intralesional triamcinolone injections.

Necrolytic migratory erythema

Benedict C. Wu, Sandra A. Kopp, and Analisa Vincent Halpern

Necrolytic migratory erythema (NME) is a characteristic paraneoplastic cutaneous reaction classically associated with an underlying gastroenteropancreatic neuroendocrine tumor (NET), most commonly a pancreatic islet α -cell neoplasm. NME has also been associated with the pseudoglucagonoma syndrome (hyperglucagonemia in the absence of a glucagon-secreting tumor),

metastatic NET, glucagon infusion–dependent states, hepatic disease, gluten-sensitive enteropathy, pancreatic insufficiency, glucagon cell adenomatosis, other malabsorption or malnutritional states, and cholangiocarcinoma. It may be associated with a polyfunctional endocrine tumor (MEN1).

NME is classically accompanied by weight loss, new-onset or worsening diabetes mellitus, normocytic anemia, and hyperglucagonemia.

The lesions begin as pruritic or painful erythematous patches with central bullae formation leading to the classic appearance of a centrally crusted, annular erosive plaque with a psoriasiform border.

NME can be widespread but has a predilection for areas subject to pressure and friction such as the buttocks, inferior abdomen, lower extremities, and intertriginous areas.

Parakeratosis and upper-level keratinocyte vacuolization are characteristic on histopathologic examination of early lesions. The pathogenesis of NME has not been fully elucidated, although several theories have emerged from observations of patient responses to various treatment strategies (e.g., tumor resection, parenteral nutrition with zinc, amino acids, essential fatty acids, etc.). One theory suggests that the catabolic effects of glucagon lead to a hypermetabolic state, resulting in the deficiency of zinc and essential fatty acids. Given the multitude of various diseases that have been associated with NME, a multifactorial model for the pathogenesis of the disease has been hypothesized: (1) hyperglucagonemia-induced hypoalbuminemia leads to deficiencies in zinc (Zn), essential fatty acids (EFA), and amino acids (AA) such as tryptophan (albumin binds and circulates Zn, AA, and EFA throughout the body); (2) Zn deficiency induces primary cutaneous inflammation, as Zn plays a major role in restoring prostaglandin-mediated inflammatory response in the epidermis; and (3) subsequent tryptophan deficiency causes keratinocyte degradation without concomitant new cell formation. Tryptophan is essential for niacin biosynthesis; without adequate niacin, keratinocytes cannot regulate proper cellular turnover, capillary tone, and appropriate maturation of epidermis and mucosal epithelia. Theoretically, this constellation of elevated serum glucagon, hypoalbuminemia, zinc, EFA and AA deficiency, and potentially hepatic dysfunction ultimately leads to the increase in epidermal inflammation, breakdown, and necrolysis observed in NME.

Necrolytic acral erythema (NAE), often associated with hepatitis C virus (HCV) infection, is considered by some to be an acral variant of NME. Despite the predominantly acral lesions of classical NAE, there have been reports of NAE over the nails, trunk, and proximal extremities as well, and one should consider the diagnosis of atypical NAE in the differential diagnosis of NME.

Management Strategy

Addressing the underlying cause of NME is paramount for treatment. In the setting of glucagonoma, *surgical resection* of the tumor is ideal; however, metastasis is commonly present at the time of diagnosis, obfuscating complete cure. Glucagonomas grow slowly and tend to be encapsulated so if caught early and fully excised adjunctive therapy is usually unnecessary. Most traditional chemotherapies are not effective in treating glucagonomas; however, some combination chemotherapy with hormonal regimens can reduce tumor burden, resulting in symptomatic improvement of NME. The *somatostatin agonists*, octreotide and lanreotide, are considered the first-line treatment of choice in NME with or without associated glucagonoma. These agents reduce conversion of proglucagon to the active form of glucagon. The use of *combination chemotherapy* targeting selective islet cells can be considered for moderately and well-differentiated tumors. Additionally, a streptozotocin (STZ)–based combination therapy may be considered for moderately and well-differentiated NETs, particularly when the tumor is pancreatic in origin, intermediate or high grade based on mitotic index or Ki-67, or exhibiting rapid clinical or radiologic progression. It has been reported that STZ and doxorubicin (DOX) combination chemotherapy in pancreatic NETs resulted in a 38% response rate and 32 months' median overall survival. For poorly differentiated NETs a platinum-based chemotherapeutic regimen, such as STZ, 5-FU, and cisplatin (FCiSt), should be considered. *Peptide receptor radioligand* therapy with radiolabeled somatostatin agonists has been tried with moderate success. *Sunitinib*, an inhibitor of multiple receptor tyrosine kinases such as vascular endothelial growth factor (VEGF) and platelet-derived growth factor (PDGF), has demonstrated improved progression-free survival in patients with advanced pancreatic NETs. Adjunctive *deep vein thrombosis (DVT) prophylaxis* should also be advised due to the risk of thromboembolism with glucagonoma. It is

clear that correcting any nutritional deficiencies in general (with correction of amino acids, essential fatty acids, or zinc specifically) should be undertaken immediately, as there is good evidence that supplementation has been associated with a marked improvement of the cutaneous lesions of NME.

A diagnosis of NME in the absence of glucagonoma should make one suspect possible underlying nutritional deficiencies or pseudoglucagonoma syndrome. These conditions can be encountered in hepatic disease and other causes of chronic malabsorption such as celiac disease, inflammatory bowel disease, chronic pancreatitis, or metastatic NET and cholangiocarcinoma. Glucagon cell adenomatosis, the diffuse enlargement of islets of Langerhans cells with resulting glucagon hypersecretion, should be expected when there is no evidence of a detectable pancreatic mass on imaging. If MEN1 or a polyfunctional endocrine tumor is suspected, one should consider investigating levels of fasting *insulin*, *prolactin*, *parathyroid hormone*, *calcium*, *vasoactive intestinal peptide (VIP)*, *gastrin*, and *adrenocorticotrophic hormone (ACTH)* in the workup.

Specific Investigations

• Serum glucagon, chromogranin	A
--------------------------------	---

- Serum zinc, amino acids (tryptophan), total protein, albumin, essential fatty acid, riboflavin, niacin, pyridoxine (vitamin B₆), cyanocobalamin (vitamin B₁₂), biotin, folic acid, pantothenic acid, methylmalonic acid, and propionic acid levels
- Hemoglobin/hematocrit
- Serum fasting glucose
- Serum liver function tests and hepatitis B and C profile
- Abdominal computed tomography (CT) scan, endoscopic ultrasound, celiac angiography, and/or somatostatin receptor scintigraphy
- Multiple endocrine neoplasia type 1 (MEN1) gene
- Serum fasting insulin, prolactin, calcium, VIP, gastrin, parathyroid hormone, ACTH
- Skin biopsy (H&E)

Glucagonoma and glucagonoma syndrome: a case report with review of recent advances in management

Al-Faouri A, Ajarma K, Alghazawi S, Al-Rawabdeh S, Zayadeen A. Case Rep Surg 2016; 2016: Article ID: 1484089, 3 pp.

This case report emphasizes the importance of recognizing the rash of NME in patients with an underlying glucagonoma/glucagonoma syndrome. New advances in the management of metastatic pancreatic NETs include liver resection, liver transplantation, long-acting somatostatin analogs, targeted radiotherapy, radioembolization with selective internal radiation microspheres, and biologic therapy.

Guidelines for the management of gastroenteropancreatic neuroendocrine (including carcinoid) tumors (NETs)

Ramage JK, Ahmed A, Ardill J, Bax N, Breen DJ, Caplin ME, et al. Gut 2012; 61: 6–32.

These guidelines have been revised by members of the UK and Ireland Neuroendocrine Tumor Society. The purpose of these guidelines is to identify and inform the key decisions to be made in the management of gastroenteropancreatic NETs. Chemotherapeutic agents included streptozotocin/doxorubicin and temozolomide/capecitabine. A streptozotocin-based combination should be considered for moderately and well-differentiated tumors, whereas a platinum-based regimen should be considered for poorly differentiated NETs.

Octreotide-responsive necrolytic migratory erythema in a patient with pseudoglucagonoma syndrome

Virani S, Prajapati V, Devani A, Mahmood M, Elliott J. J Am Acad Dermatol 2013; 68: e44–6.

A 56-year-old female with a history of ectopic Cushing syndrome with liver metastases was diagnosed with NME secondary to pseudoglucagonoma syndrome. The patient suffered from a 20-year history of recurrent painful cutaneous eruptions that failed to respond to a 2-week tapering course of prednisone. However, near resolution of lesions was observed after 4 weeks of subcutaneous administration of octreotide.

A rare but revealing sign: necrolytic migratory erythema

Compton N, Chien A. Am J Med 2013; 126: 387–9.

Patients with glucagonoma may present initially with NME. This

case report highlights the importance of maintaining high clinical suspicion of underlying malignancy, such as glucagonoma, once a diagnosis of NME is made. In this case the patient's rash was completely resolved 6 days after resection of a pancreatic tumor.

Necrolytic migratory erythema-like presentation for cystic fibrosis

Koch LH, Lewis D, Williams JV. J Am Acad Dermatol 2008; 58: S29–30.

This case report supports the chronic malabsorption syndrome (CMS) theory as a cause of NME. Patients with CMS secondary to cystic fibrosis can present with psoriasiform lesions similar to NME. In this single case report, the patient's NME-like lesions resolved after beginning nutritional therapy with zinc and hydrolyzed protein formula.

Necrolytic migratory erythema without glucagonoma in patients with liver disease

Marinkovich MP, Botella R, Datloff J, Sanguenza OP. J Am Acad Dermatol 1995; 32: 604–9.

In the absence of glucagonoma, hepatocellular dysfunction and hypoalbuminemia appear to be the most common factors associated with NME. NME may be a cutaneous marker for various liver diseases associated with malnutrition and low-protein states.

Glucagon cell adenomatosis: a new entity associated with necrolytic migratory erythema and glucagonoma syndrome

Otto AI, Marschalko M, Zalatnai A, Toth M, Kovacs J, Harsing J, et al. J Am Acad Dermatol 2001; 65: 458–9.

This report highlights a fatal case of NME in a newly recognized condition of the endocrine pancreas: glucagon cell adenomatosis.

First-Line Therapies

• Lanreotide	A
• Radiolabeled somatostatin analog	B
• Radioactive microspheres	B
• Tumor resection	B

Lanreotide in metastatic enteropancreatic neuroendocrine tumors

Caplin ME, Pavel M, Cwikla JB, Phan AT, Raderer M, Sedláčková E, et al. N Engl J Med 2014; 17: 224–33.

This randomized, double-blind, placebo-controlled, multinational study of the somatostatin analog lanreotide was shown to significantly prolong progression-free survival among patients with metastatic enteropancreatic NETs of grade 1 or 2.

Treatment with the radiolabeled somatostatin analog [177 Lu-DOTA 0,Tyr3] octreotate: toxicity, efficacy, and survival

Kwekkeboom DJ, de Herder WW, Kam BL, Van Eijck CH, Van Essen M, Kooji PP, et al. J Clin Oncol 2008; 26: 2124–30.

A total of 504 patients with gastropancreatic NETs were treated with a radiolabeled somatostatin analog with promising results for tumor-free survival, progression-free survival, and overall survival.

Radioembolization with selective internal radiation microspheres for neuroendocrine liver metastases

King J, Quinn R, Glenn DM, Janssen J, Tong D, Liaw W, et al. Cancer 2008; 1: 921–9.

This is a prospective study of 34 patients, all with nonresectable NETs with liver metastases treated with yttrium (⁹⁰Y) radioactive microspheres, who achieved long-term responses.

Surgical treatment of pancreatic neuroendocrine tumors: report of 112 cases

Gao C, Fu X, Pan Y, Li Q. Dig Surg 2010; 27: 197–204.

A retrospective review of 112 cases of pancreatic NETs. Pancreatic

NETs can be safely resected with aggressive radical surgery to improve long-term survival. Patients' 5-year survival rate was significantly correlated with vascular invasion and resection margin.

Second-Line Therapy

• Nutritional supplementation with amino acids, zinc, or essential fatty acids	D
--	----------

Glucagonoma syndrome: survival 21 years with concurrent liver metastases

Dourakis SP, Alexopoulou A, Georgousi KK, Delladetsima JK, Tolis G, Archimandritis AJ. *Am J Med Sci* 2007; 334: 225–7.

A report of unresectable glucagonoma treated symptomatically; the rash cleared with zinc supplementation.

Peripheral amino acid and fatty acid infusion for the treatment of necrolytic migratory erythema in the glucagonoma syndrome

Alexander EK, Robinson M, Staniec M, Dluhy RG. *Clin Endocrinol (Oxf)* 2002; 57: 827–31.

Long-term intermittent peripheral intravenous administration of amino acids and fatty acids led to significant improvement in NME symptoms.

Third-Line Therapies

• Streptozocin	B
• Doxorubicin	B
• Fluorouracil	B
• Everolimus	A
• Sunitinib	A
• Dacarbazine	D
• Liver transplantation	B

Fluorouracil, doxorubicin, and streptozocin in the treatment of patients with locally advanced and metastatic pancreatic endocrine carcinomas

Kouvaraki MA, Ajani JA, Hoff P, Wolff R, Evans DB, Lozano R, et al. J Clin Oncol 2004; 22: 4762–71.

This article is a retrospective look at 84 patients with locally or metastatic pancreatic endocrine carcinoma that had been treated with fluorouracil, doxorubicin, and streptozocin (FAS) to determine the role of systemic chemotherapy. The response rate to FAS was 39%, with a median response duration of 9.3 months. The 2-year progression-free survival rate was 41%, and the 2-year overall survival was 74%.

Therapeutic management of patients with gastroenteropancreatic neuroendocrine tumours

Khan MS, Caplin ME. Endocr Relat Cancer 2011; 18 Suppl 1: S53–74.

Review of therapies on the horizon for pancreatic NETs, such as peptide receptor radionuclide therapy, sunitinib, and everolimus.

Sunitinib malate for the treatment of pancreatic neuroendocrine tumors

Raymond E, Dahan L, Raoul J-L, Bang Y-J, Borbath I, Lombard-Bohas C, et al. *N Engl J Med* 2011; 364: 501–13.

A multinational, randomized, double-blind, placebo-controlled, phase III trial of sunitinib, a tyrosine kinase inhibitor, was done in patients with advanced, well-differentiated pancreatic NETs. Daily sunitinib improved progression-free survival, overall survival, and objective response rate compared with placebo.

Everolimus for advanced pancreatic neuroendocrine tumors

Yao JC, Shah MH, Ito T, Lombard-Bohas C, Wolin EW, Van Cutsem E, et al. *N Engl J Med* 2011; 364: 514–23.

In this multinational, randomized, double-blind trial, everolimus, an oral inhibitor of mammalian target of rapamycin (mTOR), was shown to significantly prolong progression-free survival among patients with progressive advanced pancreatic NETs.

Liver transplantation for the treatment of liver metastases from neuroendocrine tumors: an analysis of the UNOS database

Gedaly R, Daily MF, Davenport D, McHugh PP, Koch A, Angulo P, et al. *Arch Surg* 2011; 146: 953–8.

A retrospective analysis of 150 cases of treating liver metastases from neuroendocrine tumors with liver transplantation (LT). Longer wait times and disease stabilization before LT were associated with better outcome as well as longer progression-free survival.

Nephrogenic systemic fibrosis

Anjela Galan, and Shawn E. Cowper

Brawny induration with a woodlike texture on the lower extremity of a patient with NSF. Reprinted from Cowper SE, Robin HS, Steinberg SM, Su LD, Leboit PE. Scleromyxedema-like cutaneous disease in renal dialysis patients. *Lancet*, 356(9234) 1000 to 1, 2000, with permission from Elsevier.

Nephrogenic systemic fibrosis (NSF) affects patients with renal impairment who have been exposed to gadolinium-containing contrast agents (GCCAs) for magnetic resonance imaging (MRI) studies. Onset is marked by cutaneous erythema, edema, hyperpigmentation, and woody induration. The clinical course commonly results in joint contractures and sometimes fibrosis of

internal organs. Since the introduction of stricter use guidelines for GCCA in 2010, new cases of NSF have essentially vanished. Unfortunately, many patients exposed between 1997 and 2010 still suffer with its lingering effects. Because of the small number of affected patients and the absence of new cases, meaningful prospective human studies will likely never be possible. Animal models of NSF have been produced, however, and continue to serve as human surrogates in the development of newer and safer MRI contrast agents and in the search for future antifibrotic therapies.

Management Strategy

NSF is preventable but not curable. Three GCCAs (Magnevist, Omniscan, and Optimark) are contraindicated in patients with renal dysfunction (acute kidney injury or chronic kidney disease [estimated glomerular filtration rate (GFR) of <30 mL/min/1.73 m²]). Patients should be screened before the use of GCCAs to identify those at risk. Avoid GCCAs in patients with suspected or known impairment of drug elimination unless the need for the diagnostic information is essential and not available with alternative modalities. If exposure is unavoidable, optimal dosing and follow-up should involve the managing radiologist and nephrologist. Repeat administration of any GCCA during a single imaging session must be avoided, and sufficient time for its elimination must be allowed before reexposure. Although not proven to prevent NSF, immediate hemodialysis after exposure to a GCCA is recommended.

FDA Drug Safety Communication: new warnings for using gadolinium-based contrast agents in patients with kidney dysfunction

U.S. Food and Drug Administration;

<http://www.fda.gov/Drugs/DrugSafety/ucm223966.htm>.

Specific Investigations

- Deep skin biopsy (incisional or substantial deep punch) followed by histologic and CD34 immunohistologic evaluation by an experienced dermatopathologist
- Renal function parameters (e.g., blood urea nitrogen and

creatinine)

- Electrophoresis to exclude scleromyxedema-associated paraprotein
- Serologic autoantibody testing (e.g., ANA, Scl-70) to exclude systemic sclerosis and mixed connective tissue disease
- Hypercoagulability evaluation

There are no serologic tests for NSF. Diagnosis is based upon clinicopathologic correlation in a patient with renal disease. Gadolinium identification within skin samples is not sufficient to secure a diagnosis, and its absence does not exclude it. Consequently, testing for gadolinium is not fruitful.

Nephrogenic systemic fibrosis: clinicopathological definition and workup recommendations

Girardi M, Kay J, Elston DM, Leboit PE, Abu-Alfa A, Cowper SE. J Am Acad Dermatol 2011; 65: 1095–106.

First-Line Therapies

• Reestablishment of renal function	
• Transplantation	D
• Dialysis	D
• Physical therapy	E
• Pain management	E

Transplantation, particularly if performed soon after NSF onset, is often the best therapeutic recourse. Although the benefit is limited (approximately 50%), complete resolution may be achieved. Significant clinical improvement may slowly accrue months or years after resumption of renal function. Treatment with dialysis has mixed results. In one study half of patients on dialysis had clinical

improvement without complete resolution.

Rigorous physical therapy is mandatory to improve motion and maintain joint function.

Treatment of nephrogenic systemic fibrosis: limited options but hope for the future

Antifibrotic effect after low dose imatinib mesylate treatment in patients with nephrogenic systemic fibrosis: an open-label nonrandomized, uncontrolled clinical trial

Elmholdt TR, Buus NH, Ramsing M, Olesen AB. J Eur Acad Dermatol Venereol 2013; 27: 779–84.

Evaluation of imatinib mesylate as a possible treatment of nephrogenic systemic fibrosis in a rat model

Hope TA, LeBoit PE, High WA, Fu Y, Brasch R. Magn Res Imag 2013; 32: 139–44.

Anecdotal experience in two patients treated with 400 mg of imatinib daily showed significant improvement in symptoms at 15 weeks. Clinical effects on skin, but not on joint mobility, have been reported in three patients treated with low-dose imatinib mesylate. Additional rare case reports with similar findings are found in the literature. Two additional patients showed improvement in joint mobility and tethering that reversed upon discontinuation of therapy. The optimal period of treatment has not been determined. Administration of imatinib in rats treated with gadolinium resulted in decreased lesion severity.

Third-Line Therapies

• Sodium thiosulfate	E
• UVA1	E
• PUVA with retinoids	E
• Photodynamic therapy with methyl aminolevulinate	E
• Plasmapheresis	E
• Intravenous immunoglobulin (IVIG)	E
• Corticosteroids (topical, intralesional, and systemic)	E
• Methotrexate (systemic)	E
• Azathioprine	E
• Calcipotriene	E
• Alefacept	E
• Rapamycin	E

Nephrogenic systemic fibrosis: early recognition and treatment

Knopp EA, Cowper SE. Semin Dial 2008; 21: 123–8.

The treatments listed earlier are discussed in this review article. Most of these therapies lack large studies, reproducibility, or complete information upon which to evaluate efficacy.

The treatment of nephrogenic systemic fibrosis with therapeutic plasma exchange

Poisson JL, Low A, Park YA. J Clin Apher 2013; 28: 317–20.

Clinical symptom improvement, especially in pain levels, was reported in two patients with NSF after a series of therapeutic plasma exchange.

Neurofibromatosis, type 1

Elizabeth Ghazi, and Rhonda E. Schnur

Type 1 neurofibromatosis (NF1), or von Recklinghausen disease, is an autosomal dominant multisystem disorder with highly variable expression. NF1 is caused by mutations of the neurofibromin gene on chromosome 17. The neurofibromin protein is a GTPase-activating protein that, in its normal role, negatively regulates RAS protein signal transduction. NF1 mutations lead to overly active RAS (RAS-GTP) and, subsequently, overactivation of the mTOR (mammalian

target of rapamycin) cell-signaling pathway. Clinically, this results in excess cell growth and the potential for malignant transformation. The disorder has multisystem effects, including neurologic, cardiac, vascular, musculoskeletal, and endocrine manifestations, but cutaneous and ocular lesions (including Lisch nodules, optic gliomas, and orbital plexiform lesions) are the most characteristic. Cutaneous lesions include café au lait spots, neurofibromas, and plexiform neurofibromas. Neurofibromas may be small, benign, subcutaneous lesions or larger, plexiform tumors that follow nerves and/or extend into deeper bony and visceral structures. Malignant peripheral nerve sheath tumors (MPNSTs) may develop, particularly within larger plexiform lesions. Café au lait macules are typically the first lesions to appear in infancy and early childhood, and neurofibromas tend to proliferate during adolescence.

Management Strategy

The diagnosis of NF1 is established by well-defined clinical criteria. The sensitivity of mutation detection varies depending on the techniques used but has greatly improved. Mutation identification is useful in reproductive counseling, in confirming the diagnosis in uncertain cases, and in differentiating NF1 from other conditions with overlapping phenotypes such as the Legius and multiple lentigines syndromes. The nature of the mutation may also affect the prognosis; large deletions or null mutations are associated with more severe disease, including more severe intellectual disability and greater tumor burdens. Approximately 50% of NF1 cases represent de novo mutations.

There is currently no proven medical therapy to prevent or treat neurofibromas, but significant efforts are under way to develop targeted treatment approaches that exploit the molecular biology of the NF1 protein. Ketotifen has been used for pain, tenderness, and pruritus of neurofibromas, but there are no recent large studies using this drug. Otherwise, standard treatment for neurofibromas is currently limited to surgery. For benign neurofibromas, cosmetic concerns and discomfort are indications for removal. Most neurofibromas are small and can be removed by simple excision. Although there is little morbidity, surgery is not practical for large tumors.

A wire loop connected to a monopolar diathermy machine in the

cutting mode has been used to treat hundreds of small lesions. Hemostasis is readily obtained, healing is by secondary intention, and cosmetic outcome is good. CO₂ laser vaporization has been used for small tumors with healing by secondary intention or for larger tumors in conjunction with primary closure. Hundreds of tumors can be removed in one outpatient session under local anesthesia. Unfortunately, surgery is not curative, and lesions may continue to progress, requiring repeated procedures.

Treatment of plexiform neurofibromas is particularly challenging because these tumors are often highly vascular and invasive. Symptomatic lesions should be evaluated by magnetic resonance imaging (MRI) or positron emission tomography (PET) scans because of the risk for evolution into MPNSTs. Unexplained pain or rapid growth within a plexiform neurofibroma and areas displaying necrosis or an unusual appearance on imaging studies merit biopsy to exclude malignant transformation. cDNA gene expression profiling may be used in the future to help distinguish benign from premalignant and malignant lesions. Nonsurgical treatments for plexiform neurofibromas and MPNSTs are under active investigation. Sirolimus, an allosteric inhibitor of mTOR, has been shown to slow the progression of plexiform neurofibromas. A new generation of therapeutic agents includes angiogenesis inhibitors and antiinflammatory agents that inhibit cell growth and induce apoptosis. Drugs that target RAS signal transduction or limit RAS posttranslational processing, such as farnesyl transferase inhibitors (tipifarnib), are also promising. In addition, agents that affect the microenvironment of NF1 tumors via limiting the induction of other signaling pathways and through interactions with other cell lines are being targeted. For example, the tyrosine kinase inhibitor, imatinib mesylate, targets PDGFR α , c-KIT, and c-ABL and is being studied in phase II clinical trials. Combinations of these agents with mTOR inhibitors are also being studied.

RAS-induced transformation requires isoprenylation (i.e., farnesylation or geranyl-geranylation), which can be blocked by farnesyl transferase inhibitors as well as by 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors. HMG-CoA reductase is the rate-limiting enzyme in the mevalonate pathway that leads to the synthesis of cholesterol and isoprenyl groups. Therefore statins are also being explored in the treatment of MPNSTs and NF1-related bone dysplasia and cognitive difficulties because of

their known inhibition of p21Ras/mitogen-activated protein kinase (MAPK) activity. For tibial pseudoarthrosis, recombinant bone morphogenetic protein (an anabolic agent) and bisphosphonates (anticatabolic agents) have been used in combination to promote healing. Many of the aforementioned medications are undergoing phase II trials.

For mutations that alter gene splicing, antisense oligomers can restore splicing at the mRNA level in vitro. Tamoxifen, in vitro and in orthotopically xenografted mouse models, inhibits proliferation and survival of MPNST cells and may be a promising treatment modality.

Referral of a patient with aggressive MPNSTs to an oncologist for chemoradiotherapy may be warranted.

Information about ongoing clinical trials can be found at www.ctf.org/research/nf1 and www.ClinicalTrials.gov.

Specific Investigations

- Annual complete cutaneous examinations, particularly in those patients with large plexiform lesions
- Complete baseline ophthalmologic examination with slit lamp and dilated fundoscopy. Annual ocular examinations in children to screen for optic pathway gliomas should be continued through age 8 and every 2 years thereafter from ages 8 to 18
- Skin and eye examinations for first-degree relatives
- Regular developmental assessment in children: evaluation and management of learning disability and attention deficits, as needed
- Regular blood pressure checks to screen for renal artery stenosis or pheochromocytoma
- MRI of brain, optic nerves, and spinal cord, with and without contrast, should be performed if the patient is symptomatic and/or has focal neurologic signs
- MRI or PET scan, with and without contrast, to evaluate deep or changing plexiform neurofibromas
- Biopsy or excision of changing or suspicious lesions
- Radiographs if osseous involvement is suspected
- Genetic studies

Friedman JM. 1998 [Updated 2014]. In: Wallace SE, Amemiya A, Bean LJH. GeneReviews. Seattle: University of Washington.

<http://www.ncbi.nlm.nih.gov/books/NBK1109>.

A frequently updated, comprehensive review.

First-Line Therapies

• Surgical excision	C
• Laser therapy	B

The role of surgery in children with neurofibromatosis

Neville HL, Seymour-Dempsey K, Slopis J, Gill BS, Moore BD, Lally KP, et al. J Pediatr Surg 2001; 36: 25–9.

A large study of 249 pediatric patients with NF1 and NF2: 50 (48 with NF1) had surgery; 14 of the 50 had malignancies, and 8 underwent multiple resections. Surgical and postoperative management are reviewed.

The megasession technique for excision of multiple neurofibromas

Onesti MG, Carella S, Spinelli G, Scuderi N. Dermatol Surg 2010; 36: 1488–90.

In 15 patients, electrosurgery under general anesthesia or deep sedation was used to treat multiple neurofibromas (average 330) in a single-stage procedure. The authors proposed this method because it caused minimal discomfort and had excellent esthetic results, with a short recovery time and relatively low cost.

Treatment of neurofibromas with a carbon dioxide laser: a retrospective cross-sectional study of 106 patients

Méni C, Sbidian E, Moreno JC, Lafaye S, Buffard V, Goldzal S, et al. Dermatology 2015; 230: 263–8.

CO₂ laser treatment was well tolerated with satisfactory outcomes in over 106 patients with both symptomatic and asymptomatic neurofibromas.

Management and prognosis of malignant peripheral nerve sheath tumors: the experience of the French Sarcoma Group (GSF-GETO)

Valentin T, Le Cesne A, Ray-Coquard I, Italiano A, Decanter G, Bompas E, et al. Eur J Cancer 2016; 56: 77–84.

A total of 353 patients with MPNSTs, including 37% with NF1, were analyzed. Curative-intent surgery was undertaken in 294. Of these, 21% had neoadjuvant treatment (mainly chemotherapy), and 59% had adjuvant treatment (mainly radiotherapy). For operated patients, the median progression-free survival was 26.3 months. MPNST patients with NF1 who were treated with palliative chemotherapy showed worse survival than patients with sporadic forms of MPNSTs. This is the largest study of MPNST to date.

Second-Line Therapies

• Ketotifen	B
• Chemotherapy	D

Ketotifen suppression of NF1 neurofibroma growth over 30 years
Riccardi VM. Am J Med Genet A 2015; 167: 1570–7.

A single NF patient was observed to have arrested growth of neurofibromas.

Chemotherapy benefit for pediatric neurofibromatosis type I

Brower V. Lancet Oncol 2016; 17: e186.

Significantly better 5-year event-free survival (69%) was observed in 127 patients with NF1 and low-grade gliomas who were treated

with carboplatin and vincristine, compared with 137 patients without NF1 who were similarly treated (39%).

Third-Line Therapies

• Imatinib	E
• mTOR inhibitor (sirolimus, rapamycin)	B, E
• VEGF/c-KIT inhibitor (bevacizumab, cediranib)	D, E
• Multikinase inhibitor (sorafenib)	E
• Tamoxifen	E
• Statins (simvastatin, lovastatin)	A, B
• Pirfenidone	B
• Radiofrequency	D
• BRAF inhibitors (vemurafenib)	E
• Interferon alpha	D
• Antisense morpholino oligomers	E

Imatinib mesylate for plexiform neurofibromas in patients with neurofibromatosis type 1: a phase 2 trial

Robertson KA, Nalepa G, Yang FC, Bowers DC, Ho CY, Hutchins GD, et al. Lancet Oncol 2012; 13: 1218–24.

Patients were treated with oral imatinib mesylate at 220 mg/m² twice daily for children and 400 mg twice daily for adults for 6 months. Of the 23 patients who received imatinib for at least 6 months, 6 (26%) had a 20% or more decrease in volume of one or more plexiform tumors. Adverse effects included reversible neutropenia and hyperglycemia.

Sirolimus for nonprogressive NF1–associated plexiform neurofibromas: an NF clinical trials consortium phase II study

Weiss B, Widemann BC, Wolters P, Dombi E, Vinks AA, Cantor A,

et al. *Pediatr Blood Cancer* 2014; 61: 982–6.

This trial studied 13 patients with nonprogressive plexiform neurofibromas using a starting dose of sirolimus of 0.8 mg/m² body surface area by mouth, given twice daily for a 28-day course. None of the patients had severe toxicity. However, sirolimus did not induce shrinkage of nonprogressive peripheral neurofibromas; therefore the authors suggested that sirolimus should not be considered as a treatment option for nonprogressive tumors. However, an unexpected significant improvement in the mean scores of the emotional and school domains in a quality of life questionnaire was reported in six individuals.

Sirolimus for progressive neurofibromatosis type 1-associated plexiform neurofibromas: a neurofibromatosis Clinical Trials Consortium phase II study

Weiss B, Widemann B, Wolters P, Dombi E, Vinks AA, Cantor A, et al. *Neuro Oncol* 2015; 17: 596–603.

This study was focused on patients with inoperable, NF1-associated, progressive plexiform neurofibromas. Twenty-nine patients were treated with sirolimus and 49 with placebo. Two subjects were removed from the trial for severe sirolimus toxicity (grade 2 pneumonitis; both cases reversed with cessation of therapy). Sirolimus prolonged the time to progression of plexiform neurofibromas by almost 4 months in these NF1 patients.

Prolonged survival in adult neurofibromatosis type I patients with recurrent high-grade gliomas treated with bevacizumab

Theeler BJ, Ellezam B, Yust-Katz S, Slopis JM, Loghin ME, de Groot JF. *J Neurol* 2014; 261: 1559–64.

Five patients with recurrent high-grade gliomas were treated with a median of 20 cycles of bevacizumab (ranging from 10–72 months). All five experienced prolonged postrecurrence survival. The median overall survival from the time of glioma diagnosis was 72.6 months. Three out of five patients developed vascular complications leading to discontinuation of the drug.

Tamoxifen inhibits malignant peripheral nerve sheath tumor growth in an estrogen-receptor independent manner

Byer S, Eckert JM, Brossier NM, Clodfelder-Miller BJ, Turk AN, Carroll AJ, et al. *Neuro Oncol* 2011; 13: 28–41.

A tamoxifen metabolite, 4-hydroxy-tamoxifen, inhibited proliferation and survival of MPNST cells in vitro and in an orthotopic xenograft mouse model.

A randomized placebo-controlled lovastatin trial for neurobehavioral function in neurofibromatosis I

Bearden CE, Hellemann GS, Rosser T, Montojo C, Jonas R, Enrique N, et al. *Ann Clin Transl Neurol* 2016; 3: 266–79.

Forty-four NF1 patients were randomly assigned to 14 weeks of lovastatin (maximum dose of 80 mg/day for adult participants and 40 mg/day for children) or placebo. Differential improvement favoring lovastatin treatment was observed for one primary outcome measure (working memory) and two secondary measures (verbal memory and adult self-reported internalizing problems).

Phase II trial of pirfenidone in children and young adults with neurofibromatosis type 1 and progressive plexiform neurofibromas

Widemann BC, Babovic-Vuksanovic D, Dombi E, Wolters PL, Goldman S, Martin S, et al. *Pediatr Blood Cancer* 2014; 61: 1598–602.

Thirty-six NF1 patients with progressive plexiform neurofibromas were treated with pirfenidone. The median time to progression for pirfenidone-treated patients was 13.2 months compared with 10.6 months for the placebo control group. No objective responses were observed. Pirfenidone was well tolerated but did not demonstrate sufficient beneficial activity to warrant its use.

Radiofrequency in the treatment of craniofacial plexiform neurofibromatosis: a pilot study

Baujat B, Krastinova-Lolov D, Blumen M, Baglin AC, Coquille F, Chabolle F. *Plast Reconstruct Surg* 2006; 117: 1261–8.

This five-patient pilot study demonstrated partial diminution or stabilization of plexiform neurofibromas using radiofrequency treatment. Treatment was well tolerated, with the best effects observed in the early stages of the disease.

Interferon-[alpha] for unresectable progressive and symptomatic plexiform neurofibromas

Kebudi R, Cakir FB, Gorgun O. *J Pediatr Hematol Oncol* 2013; 35: e115–7.

IFN-alpha 2a at a dose of 3,000,000 U/m²/SC was given three times a week, every other day, to five patients. The dose was increased to 6,000,000 U/m² SC three times weekly and continued for 1 year. Four out of five patients had stable disease; one progressed to MPNST. Follow-up ranged from 2 to 10 years.

Chemotherapy for the treatment of malignant peripheral nerve sheath tumors in neurofibromatosis 1: a 10-year institutional review

Zehou O, Fabre E, Zelek L, Sbidian E, Ortonne N, Banu E, et al. Orphanet J Rare Dis 2013; 8: 127.

This retrospective review of 21 NF1 patients with MPNSTs who were treated with standard chemotherapy (anthracycline and/or ifosfamide) showed that conventional chemotherapy does not reduce mortality.

Nevoid basal cell carcinoma syndrome

Maral Kibarian Skelsey, and Gary L. Peck

Nevoid basal cell carcinoma (Gorlin) syndrome (NBCCS) is an autosomal dominant syndrome characterized by basal cell carcinomas (BCCs) and multiple systemic manifestations. These may include palmar or plantar pits, odontogenic keratocysts of the jaw, ectopic intracranial calcification (falx cerebri), fused or bifid ribs,

macrocephaly, cleft lip, coarse facies, hypertelorism, medulloblastomas, cardiac and ovarian fibromas, lymphomesenteric cysts, pectus deformity, and syndactyly of the digits.

For most patients NBCCS is caused by mutations in a tumor suppressor patched (PTCH)1 gene, mapped to the long arm of chromosome 9(q2231). The PTCH1 gene encodes a transmembrane protein that acts as a receptor to the hedgehog protein and affects the sonic hedgehog signaling pathway (SHH). The PTCH1 protein binds to the transmembrane protein, smoothened (SMO), and inhibits the SHH signal pathway. SMO promotes release of Gli proteins from suppressor of fused (SUFU), its inhibitor. Mutations in the PTCH1 gene result in an overexpression of the SHH pathway and formation of neoplasms and specific developmental anomalies. Patients without the PTCH gene mutation may have a mutation in SUFU, which results in overactivation of Gli transcription factors and cell proliferation. This subtype of NBCCS may exhibit medulloblastoma before age 5 and an absence of odontogenic keratocysts. Rarely, mutations in PTCH2 may also have an association with NBCCS.

Management Strategy

The management of NBCCS patients is focused on patient education, tumor prevention, and treatment of BCC while optimizing cosmesis and minimizing discomfort and cost.

Patient education should include information on *sunscreens, sun protective clothing and eyewear, UV films* for car windows, and the necessity of *avoiding radiation treatment*, as well as *genetic counseling*. Patients should be tested regularly for *vitamin D* deficiency, prescribed supplementation based on their laboratory values, and be examined for clinical features of deficiency. Full-body skin examinations should be performed on an annual basis and at more frequent intervals after the development of the first skin cancer. The dermatologist has a role as an advocate and resource for these patients, who may need referrals to other specialists for diagnosis and treatment of the extracutaneous implications of NBCCS. In particular, annual ophthalmologic and dental examinations should be performed. Pediatric patients should be followed up and undergo developmental, vision, speech, and hearing screenings. A baseline echocardiogram can rule out a potentially dangerous cardiac fibroma. Pelvic ultrasound should be considered in girls who have reached

puberty. As there is a need to limit radiation exposure, routine x-rays to establish syndrome criteria are unnecessary unless the diagnosis is uncertain. Digital imaging is preferable when possible. An annual magnetic resonance imaging (MRI) of the head is recommended until the age of 8 when medulloblastoma becomes rare.

Genetic testing can be limited to the following situations: (1) prenatal testing if the diagnosis is confirmed in a family member; (2) establishing the diagnosis in patients who do not meet sufficient criteria; and (3) screening an asymptomatic patient who is at risk because of an affected family member.

Patients with NBCSS need *emotional support* as they undergo multiple treatments that may result in scarring and deformity. They may benefit from regular screening for depression and referral to a support network where this is available (e.g., www.Gorlinsyndrome.org).

The size and numbers of tumors, especially in those with type I and II skin, the young age at presentation, and the distribution on the head and neck, pose challenges greater than those associated with sporadic BCC. Nonetheless, with the notable exception of radiotherapy, which should be avoided, treatment is based on the same modalities including *surgery; laser resurfacing; photodynamic therapy*; and topical, injectable, and systemic therapy, including *vismodegib*, an SHH pathway inhibitor that binds SMO, and *capecitabine*, a systemic fluorouracil prodrug.

The role of *chemoprevention* (prophylactic therapy to reduce the incidence of new BCCs) is still unclear. Evidence for efficacy in NBCCS is inconclusive, except for vismodegib, which is not well tolerated but may find a role here.

This chapter is focused largely on the literature specific to NBCCS, and the reader is referred to the chapter on BCC for a broader review of the management of this tumor.

Specific Investigations

- Radiologic studies
- Dermatoscopy
- Vitamin D level
- Genetic studies (in selected cases)

Consensus statement from the first international colloquium on basal cell nevus syndrome (BCNS)

Bree AF, Shah MR. Am J Med Genet A 2011; 155: 2091–7.

This is a multidisciplinary consensus group's statement on the diagnostic criteria for NBCCS and protocols for evaluation and surveillance of pediatric and adult patients.

High prevalence of vitamin D deficiency in patients with basal cell nevus syndrome

Tang J, Wu A, Linos E, Parimi N, Lee W, Aszterbaum M, et al. Arch Dermatol 2010; 146: 1105–10.

Levels of 25-hydroxyvitamin D (25[OH]D) were measured in 41 ambulatory patients with NBCCS who were participating in a 2-year chemoprevention clinical trial. Population-based controls were selected and matched by age, sex, Fitzpatrick skin type, and season/geography. NBCCS patients were three times more likely to be vitamin D deficient (56% vs. 18%; $p < 0.001$).

First-Line Therapies

• Surgical management	B
• Mohs micrographic surgery	B
• Avoidance of ultraviolet light and radiotherapy	B

Consensus for nonmelanoma skin cancer treatment: basal cell carcinoma, including a cost analysis of treatment methods

Kauvar AN, Cronin T, Roenigk R, Hruza G, Bennett R. Dermatol Surg 2015; 41: 550–71.

Tumor factors associated with increased recurrence rates of BCC include location on the “mask” area of the midface, hands, feet, and genitalia; size over 20 cm on the torso or extremities and 10 mm or larger in the nonmask areas of the face; micronodular, infiltrative, sclerosing, morpheaform, or desmoplastic histologic subtypes; ill-defined margins; prior recurrence; and perineural invasion. Host factors linked to high-risk BCC include occurrence in a site of prior

radiation or scar, immunosuppression, genetic syndrome, and age younger than 40.

The nevoid basal cell carcinoma syndrome: sensitivity to the ultraviolet and x-ray irradiation

Frentz G, MunchPetersen B, Wulf HC, Niebuhr E, da Cunha Bang F. J Am Acad Dermatol 1987; 17: 637–43.

Radiation therapy should be avoided in patients with NBCCS because these patients develop BCC as a consequence of radiotherapy within 6 months to 3 years, in contrast to the usual 20- to 30-year lag period for radiation-induced tumors seen in patients with sporadic BCC.

Sun exposure and basal cell carcinomas in the nevoid basal cell carcinoma syndrome

Goldstein AM, Bale SJ, Peck GL, DiGiovanna JJ. J Am Acad Dermatol 1993; 29: 34–41.

The distribution of tumors in NBCCS, favoring sun-exposed sites, would indicate that solar irradiation may be an exacerbating factor.

Second-Line Therapy

- | | |
|------------------------------------|----------|

|------------------------------------|----------|

Basal cell and squamous cell skin cancers: clinical practice guidelines in oncology

Miller SJ, Alam M, Anderson J, Berg D, Bichakjian CK, Bowen G, et al. JNCCN 2010; 8: 836–64.

Surgery results in the highest cure rate and lowest recurrence for BCC. Electrodesiccation and curettage is effective for low-risk tumors in non-hair-bearing areas if fat is not reached. Pathology should be obtained to exclude high-risk tumor. Excisions with 4-mm clinical margins are usually adequate. High-risk tumors should be treated with Mohs surgery or excision with complete circumferential peripheral and deep margin assessment with frozen or permanent section.

Third-Line Therapies

• Photodynamic therapy (PDT)	A
• Imiquimod	A
• Cryosurgery	B
• 5-Fluorouracil (5FU)	B
• CO ₂ laser	B
• Pulsed dye laser (PDL)	C
• Alexandrite laser	E
• Interferon	B
• Bleomycin	B
• Electrochemotherapy	E
• Retinoids	C
• Interleukin-2 (IL-2)	C
• Paclitaxel	E
• Capecitabine	E
• Chemical peel	E
• Dermabrasion	E
• Vismodegib (in locally advanced or metastatic BCC)	A
• Sonidegib	B
• Ingenol mebutate	D

Treatment of Gorlin syndrome (nevroid basal cell carcinoma syndrome) with methylaminolevulinate photodynamic therapy in seven patients, including two children: interest of tumescent anesthesia for pain control in children

Girard C, Debu A, Bessis D, Blatière V, Dereure O, Guillot B. J Eur

Acad Dermatol Venereol 2013; 27: e171–5.

Seven patients with 41 BCCs had prior superficial curettage for sBCCs or debulking for nBCCs, then had methyl aminolevulinic (MAL) acid applied topically to lesions 3 hours before illumination with 635 nm red light for 10 minutes. Overall clearance in patients was 60% after one session and 78% after three sessions. There were excellent cosmetic outcomes in all patients. Treatments were well tolerated in adults with moderate pain sensation during illumination, and a ropivacaine–lidocaine tumescent anesthesia was used on the youngest patient to ensure excellent pain tolerance.

Efficacy of photodynamic therapy as a treatment for Gorlin syndrome-related basal cell carcinomas

Loncaster J, Swindell R, Slevin F, Sheridan L, Allan D, Allan E. Clin Oncol 2009; 21: 502–8.

Thirty-three NBCCS patients (138 lesions) were treated with PDT, and lesion thicknesses were assessed using ultrasound, both before treatment and during follow-up. Topical PDT was used to treat superficial lesions (<2 mm thick) and a systemic photosensitizer + light delivered by interstitially placed optical fibers, which extended the remit of PDT, allowed for thicker lesions (>2 mm) to be treated. Local control rates of 56.3% at 12 months were achieved overall.

Consensus recommendations for the treatment of basal cell carcinomas in Gorlin syndrome with topical methylaminolevulinate-photodynamic therapy

Basset-Seguin N, Bissonnette R, Girard C, Haedersdal M, Lear JT, Paul C, et al. J Eur Acad Dermatol Venereol 2014; 28: 626–32.

Seven dermatologists developed consensus recommendations for the treatment of BCC with MAL-PDT in BCNS patients based on their extensive experience and review of the literature. They conclude that all superficial BCC (sBCC) and nodular BCC (nBCC) <2 mm in depth may be treated and that periorificial sBCC and nBCC may be considered for treatment. Multiple tumors may be treated simultaneously if pain management is adequate. Although MAL-PDT is not approved for pediatric use, the panel agreed, based on case studies and the experts' pediatric experience, that treatment of children may be considered.

Photodynamic therapy for patients with basal cell nevus

syndrome

Gilchrest BA, Brightman LA, Thiele JJ, Wasserman DI. *Dermatol Surg* 2009; 35: 1576–81.

Seven cases were treated with aminolevulinic acid (ALA)-PDT intermittently at 15-month intervals over broad areas of the face and parts of the torso and extremities. A 20% ALA solution was applied for a 1-hour incubation and the area was exposed to blue light (417 nm) for 16 minutes, 40 seconds. Patients were followed for 7 years and experienced resolution of the majority of BCC and reduction in the number of new BCC, as well as improvement in their cosmetic appearance.

Photodynamic therapy versus topical imiquimod versus topical fluorouracil for treatment of superficial basal cell carcinoma: a single-blind, non-inferiority, randomized clinical trial

Arits AH, Mosterd K, Essers BA, Spoorenberg E, Sommer A, De Rooij MJ, et al. *Lancet Oncol* 2013; 14: 647–54.

In this trial, 601 patients with sBCC were randomized to receive two sessions of MAL-PDT (1-week interval), imiquimod cream once daily five times a week for 6 weeks, or fluorouracil 5% cream twice daily for 4 weeks. The percentage of tumor-free patients at both 3- and 12-month follow-up was 72.8% (95% confidence interval [CI], 66.8–79.4) for PDT, 83.4% (78.2–88.9) for imiquimod, and 80.1% (74.7–85.9) for fluorouracil.

Cryosurgery for cutaneous malignancy: an update

Kuflik EG. *Dermatol Surg* 1997; 23: 1081–7.

Cryosurgery is best suited for superficial noninfiltrating tumors with well-defined borders. Cryosurgery is not effective for morpheaform or infiltrating histologic subtypes, recurrent lesions, or deeply penetrating or very aggressive tumors.

Gorlin syndrome: the role of the carbon dioxide laser in patient management

Grobbelaar AO, Horlock N, Gault DT. *Ann Plast Surg* 1997; 39: 366–73.

Ultrapulse CO₂ used for the successful treatment of basal cell carcinomas found in patients with basal cell nevus syndrome

Nouri K, Chang A, Trent JT, Jiménez GP. *Dermatol Surg* 2002; 28: 287–90.

Three patients with multiple small BCCs were effectively treated with ultrapulse CO₂ laser, with complete histologic clearance and minimal scarring noted at follow-up.

Although sBCCs can be ablated to the mid-dermis or deeper with 100% clearance, large nBCCs with diameters greater than 10 mm cannot reliably be removed with this method.

Single treatment of nonmelanoma skin cancers using a pulsed-dye laser with stacked pulses

Tran HT, Lee RA, Oganessian G, Jiang SB. *Lasers Surg Med* 2012; 44: 459–67.

Twenty patients with 23 biopsy-proven BCCs and squamous cell carcinoma (SCC) in situ were randomized to receive either no treatment or 595 nm PDL, either without or with double (stacked) pulses. The nonstacked treatment group had a clearance rate of 25% (similar to the nontreated group), whereas the double-stacked group had a clearance rate of 71%. The lesions with residual tumors were noted to be beyond the central treatment zone by histopathology and, if excluded, resulted in a clearance rate of 100%.

755 nm alexandrite laser for the reduction of tumor burden in basal cell nevus syndrome

Ibrahimi OA, Sakamoto FH, Tannous Z, Anderson RR. *Lasers Surg Med* 2011; 43: 68–71.

Targeting the vasculature has been recognized as a means of eradicating tumors; however, vascular lasers such as the PDL have limited efficacy in the treatment of BCC. The long-pulsed alexandrite can penetrate twice the depth of the PDL and can reach the vasculature of the dermis. A BCNS patient with a history of radiation therapy was treated on the upper extremities and anterior trunk with the 755 nm alexandrite laser with two passes at an energy of 100 J/cm², pulse length of 3 milliseconds, no dynamic cooling mode, and 8-mm spot size with 10% overlapping between pulses. Fifteen of 18 treated lesions showed complete clinical response and appeared at 7 months as a hypopigmented scar. Biopsy of a single lesion at 7 months showed no residual BCC.

Intralesional agents in the management of cutaneous

malignancy: a review

Good LM, Miller MD, High WA. J Am Acad Derm 2011; 64: 413–22.

Intralesional treatment of skin cancer is a consideration when surgical intervention is not a viable option and for cases where cosmetic outcome may be compromised with surgery. Interferons alpha-2b (1.5 M IU, 3 times weekly for 3 weeks) and also beta-1a are used for BCC. There is little experience of this modality in NBCCS.

Successful treatment of multiple basaliomas with bleomycin-based electrochemotherapy: a case series of three patients with Gorlin-Goltz syndrome

Kis E, Baltas E, Kinyo A, Varga E, Nagy N, Gyulai R, et al. Acta Derm Venereol 2012; 92: 648–51.

In electrochemotherapy (ECT) tumors are destroyed when electric pulses are delivered at the same time as a chemotherapeutic agent is administered; this is thought to increase the local cytotoxicity of the anticancer drug. Three patients with BCNS and a total of 99 BCCs on the face, scalp, trunk, and extremities received intravenous bleomycin-based ECT at a dose of 15 mg/m² while under general sedation. Tumors ranged in size from 0.32 to 0.2 cm³. Electrical pulses were delivered during the pharmacokinetic peak, 828 minutes after the intravenous administration of bleomycin. The types of electrodes used varied depending on the size and type of tumor. One patient underwent four treatment sessions spaced at 2-month intervals; the remainder were treated only once. Complete response (CR) of tumors occurred in 87%, with partial response in 12%. No recurrence was observed during a 10–28 month follow-up. Histology of two tumors confirmed CR. Side effects were limited to erythema and edema around treated lesions, necrosis of treated lesions for 2–3 weeks, and sore muscles at time of pulse delivery.

Electrochemotherapy: a valid treatment for Gorlin-Goltz syndrome

Curatolo P, Miraglia E, Rotunno R, Calvieri S, Giustini S. Acta Dermatovenereol Croat 2013; 21: 132–4.

A BCNS patient with a 5 × 10 cm BCC on the scalp was treated with bleomycin-based ECT at a dose of 15 mg/m². An initial necrotic eschar on the nodule reepithelialized at 4 weeks, at which time a second ECT was performed. After 4 weeks there was complete response of the tumor with no recurrence after 4 years.

Effect of perilesional injections of PEG-interleukin-2 on basal cell carcinoma

Kaplan B, Moy RL. *Dermatol Surg* 2001; 26:1037–40.

Twelve BCCs in eight patients were treated with intralesional pegylated IL2, with a 66% (8/12) clinical and histologic cure rate. Erythema, swelling, and pain occurred in 10/12 injection sites but resolved in a week's time, and only one patient experienced systemic flulike symptoms.

Successful treatment of an intractable case of hereditary basal cell carcinoma syndrome with paclitaxel

El Sobky RA, Kallab AM, Dainer PM, Jillella AP, Leshner JL Jr. *Arch Dermatol* 2001; 137: 827–8.

Novel approach to Gorlin syndrome: a patient treated with oral capecitabine

Beach DF, Somer R. *J Clin Oncol* 2011; 29: e397–401.

Capecitabine, a systemic prodrug of fluorouracil (FU), is metabolized in the liver and then converted to the active form of FU by cytidine deaminase, an enzyme found in tumor cells. A patient with NBCCS with only limited response to topical FU was treated with oral capecitabine 1500 mg orally every 12 hours for 14 days, every 3 weeks. After 6 months he had near-complete resolution of a 2 × 2.5 cm BCC on the scalp and near-complete resolution of a 2.5 × 1.5 cm BCC on the scapula. Multiple lesions completely cleared, and no new lesions developed during the 2 years the patient has been on the medication.

Efficacy and safety of vismodegib in advanced basal cell carcinoma

Sekulic A, Migden MR, Oro AE, Dirix L, Lewis KD, Hainsworth JD, et al. *N Engl J Med* 2012; 366: 217–9.

In a phase II pivotal study (ERIVANCE BCC), 104 patients with advanced BCC (71 locally advanced, 33 metastatic) received 150 mg of oral vismodegib (G DC0449) daily.

The response rate was 30% in patients with metastatic BCC and 43% in patients with locally advanced BCC, with complete responses in 21% of these patients. Adverse events occurring in more than 30% of patients were muscle spasms, alopecia, dysgeusia, weight loss, and fatigue. Serious adverse events were attributed to treatment with

vismodegib in 4% of patients.

Surgical excision after neoadjuvant therapy with vismodegib for a locally advanced basal cell carcinoma and resistant basal cell carcinomas in Gorlin syndrome

Chang ALS, Atwood SX, Tartar DM, Oro AE. JAMA Dermatol 2013; 149: 639–41.

Treatment of an NBCCS patient with vismodegib 150 mg/day for 51 weeks resulted in regression of his advanced BCC, facilitating tumor extirpation. While on vismodegib, however, the patient acquired secondary resistance and developed new tumors.

Patient with Gorlin syndrome and metastatic basal cell carcinoma refractory to smoothened inhibitors

Zhu GA, Li AS, Chang AL. J Am Acad Dermatol 2014; 150: 877–9.

A patient with NBCCS and BCC metastatic to the lung was initially treated with a new SMO inhibitor saridegib at 130 mg/d. Because the tumor was unresponsive after 16 months, he was started on vismodegib and continued to experience growth of both preexisting and new nodules.

The use of vismodegib to shrink keratocystic odontogenic tumors in patients with basal cell nevus syndrome

Ally MS, Tang JU, Joseph T, Thompson B, Lindgren J, Raphael MA, et al. JAMA Dermatol 2014; 150: 542–5.

Vismodegib may be a nonsurgical treatment option for keratocystic odontogenic tumors (KCOTs) in NBCCS patients. In six patients with both BCNS and KCOT, tumor size was reduced by 50% after vismodegib 150 mg/d for a mean of 18 months. There was no new KCOT development during therapy. Long-term efficacy is unknown, and it is not clear why some patients did not respond.

An investigator-initiated open-label clinical trial of vismodegib as a neoadjuvant to surgery for high-risk basal cell carcinoma

Ally MS, Aasi S, Wysong A, Teng C, Anderson E, Bailey-Healy I, et al. J Am Acad Dermatol 2014; 71: 904–11.

Eleven patients with advanced BCC were treated with vismodegib 150 mg/day for a mean of 4 months, which reduced the surgical defect area by 27% (95% CI, 45.7%–7.9%; $p = 0.006$). Treatment was limited by severe side effects, and 29% of patients could not complete more

than 3 months because of adverse events. No effect was seen with treatment less than 3 months.

Vismodegib exerts targeted efficacy against recurrent sonic hedgehog subgroup medulloblastoma: results from phase II pediatric brain tumor consortium studies PBTC025b and PBTC032

Robinson GW, Orr BA, Wu G, Gururangan S, Lin T, Qaddoumi I, et al. *J Clin Oncol* 2015; 33: 2646–54.

Phase II study of vismodegib in 31 pediatric and adult recurrent medulloblastoma (MB) patients showed that vismodegib retains activity against adult recurrent SHH-MB but not against non-SHH-MB. Data on pediatric patients were insufficient.

Topical treatment of basal cell carcinomas in nevoid basal cell carcinoma syndrome with a smoothened inhibitor

Skavara H, Kalthoff F, Meingassner JG, Wolff-Winiski B, Aschauer H, Kelleher JF, et al. *J Invest Dermatol* 2011; 131: 1735–44.

LDE225 (sonidegib) cream, a selective inhibitor of SMO, has shown inhibition of murine basaloid cells in organ cultures of PTCH1 heterozygotes. Eight BCNS patients participated in a double-blind, randomized, placebo-controlled study of 75% LDE225 cream or vehicle. After 4 weeks complete response was observed in 3 of 13 LDE225-treated BCC; 9 showed partial response. One had no clinical response. Treatment was well tolerated.

PEP005 (ingenol mebutate) gel for the topical treatment of superficial basal cell carcinoma: results of a randomized phase IIa trial

Siller G, Rosen R, Freeman M, Welburn P, Katsamas J, Ogbourne SM. *Australas J Dermatol* 2010; 51: 99–105.

Although developed for treatment of actinic keratoses, topical ingenol mebutate gel 0.05% showed histologic clearance of sBCC in 63% of patients ($n = 8$). Side effects included local skin reactions, application-site pain, and headache.

Chemoprevention

• Retinoids	D
• Nonsteroidal antiinflammatory drugs (NSAIDs)	C
• Vismodegib	A

Chemoprevention of basal cell carcinoma with isotretinoin

Peck GL, Gross EG, Butkus D, DiGiovanna JJ. J Am Acad Dermatol 1982; 6(Suppl 2): 815–23.

Treatment and prevention of basal cell carcinoma with oral isotretinoin

Peck GL, DiGiovanna JJ, Sarnoff DS, Gross EG, Butkus D, Olsen TG, et al. J Am Acad Dermatol 1988; 19: 176–85.

Eight percent of 270 tumors due to NBCCS, arsenic exposure, or sunlight exposure in 12 patients treated with a mean dose of 3.1 mg/kg/day for 8 months underwent complete clinical and histologic regression. Lower doses given to 3 patients for 3 to 8 years were effective for chemoprevention of new BCCs.

Effectiveness of isotretinoin in preventing the appearance of basal cell carcinomas in basal cell nevus syndrome

Goldberg LH, Hsu SH, Alcalay J. J Am Acad Dermatol 1989; 21: 144–5.

Etretinate treatment of the nevoid basal cell carcinoma syndrome. Therapeutic and chemopreventive effect

Hodak E, Ginzburg A, David M, Sandbank M. Int J Dermatol 1987; 26: 606–9.

Efficacy of retinoids in preventing development of BCCs has been reported only in a few cases of NBCCS, and the sparsity of these reports renders them somewhat unconvincing.

Basal cell carcinoma chemoprevention with nonsteroidal anti-inflammatory drugs in genetically predisposed PTCH1^{+/-} humans and mice

Tang JY, Aszterbaum M, Athar M, Barsanti F, Cappola C, Estevez N, et al. Cancer Prev Res 2010; 3: 253–4.

A 3-year, double-blind, randomized clinical trial in 60 PTCH1[±] patients with NBCCS assessed the effects of oral celecoxib on the development of BCCs. A trend for reducing BCC burden was detected ($p = 0.069$), and the effect appeared most pronounced in patients with less severe disease. The study was discontinued because of concern over enhanced cardiovascular risks.

Inhibiting the hedgehog pathway in patients with the basal cell nevus syndrome

Tang JY, Mackay-Wiggan JM, Aszterbaum M, Yauch RL, Lindgren J, Chang K, et al. N Engl J Med 2012; 366: 2180–8.

In a randomized, double-blind, placebo-controlled, 18-month study, vismodegib reduced the incidence of new, clinically significant BCC (2 vs. 29 cases per group per year, $p < 0.001$). Percent change in baseline size of BCC was found to be 65% versus –11%, $p = 0.003$. No tumors progressed while on vismodegib. Because of adverse events, 54% of patients discontinued vismodegib before the planned conclusion of the study.

Intermittent vismodegib therapy in basal cell nevus syndrome

Yang X, Dinehart SM. JAMA Dermatol 2016; 152: 223–4.

Two patients with NBCCS underwent intermittent therapy with vismodegib: one treated daily for 1 month with 2 months off and the other 2 months on and 2 months off. Side effects resolved within 1 month of the drug holiday, allowing the regimen to be well tolerated. Efficacy was comparable to other trials, with a mean of 1.4 new BCC per year, per patient.

Tazarotene: randomized, double-blind, vehicle-controlled, and open-label concurrent trials for basal cell carcinoma prevention and therapy in patients with basal cell nevus syndrome

Tang JY, Chiou AS, Mackay-Wiggan JM, Aszterbaum M, Chanana AM, Lee W, et al. Cancer Prev Res 2014; 7: 292–9.

In studies on 36 and 34 patients, respectively, topical tazarotene did not appear effective in curing or preventing BCCs in NBCCS.

Nevus sebaceus

Stuart R. Lessin, and Clifford S. Perlis

Nevus sebaceus, first described by Jadassohn in 1895, is a term for a congenital hamartoma of the epidermis and adnexal structures typically involving the scalp and face. It results from the mosaic expression of HRAS and KRAS gene mutations. It presents at birth or appears in early childhood as a pink, orange, or yellow waxy plaque with a granular pitted surface that is often hairless. The size and configuration can be variable. During puberty the lesion thickens and becomes verrucous as glands enlarge within the dermis. Development of cutaneous and adenexal neoplasms has been reported in 10% to 20% of lesions after puberty and in adulthood. These neoplasms are most commonly benign. Surgical treatment addresses cosmetic issues, as well as prophylaxis or treatment of neoplasms.

Management Strategy

For most lesions, clinical examination is sufficient to establish the diagnosis. A skin biopsy can confirm the clinical impression when indicated. Most neoplastic growths that arise in a nevus sebaceus do not develop until after the age of 16 years; the overwhelming majority is benign. These include syringocystadenoma papilliferum, trichoblastoma, tricholemmoma, sebaceoma, nevocellular nevus, and seborrheic keratosis. The most common malignancy that develops within a nevus sebaceus is a basal cell carcinoma, but the absolute incidence is very rare. Isolated case reports describe rare patients who have developed sebaceous carcinoma, squamous cell carcinoma, tricholemmal carcinoma, or microcystic adnexal carcinoma within nevus sebaceus.

In 2000 case series established that trichoblastoma was the most common neoplasm arising in nevus sebaceus. With this evidence of minimal risk of malignant neoplastic transformation, prophylactic surgery is not justified. Conservative management with clinical observation and biopsy of any lesions suspicious for malignancy appear to be most prudent.

Tumors arising in nevus sebaceus: a study of 596 cases

Cribier B, Scrivener Y, Grosshans E. J Am Acad Dermatol 2000; 42: 263–8.

Retrospective case series of 596 cases demonstrating a 1.7% occurrence of benign tumors in childhood. Most tumors arising in nevus sebaceus occurred in adults over 40; in these adults, 2.1% of the neoplasms were basal cell carcinomas. The authors conclude that prophylactic surgery in children is of uncertain benefit.

Trichoblastoma is the most common neoplasm developed in nevus sebaceus of Jadassohn: a clinicopathologic study of a series of 155 cases

Jaqueti G, Requena L, Sánchez Yus E. Am J Dermatopathol 2000; 22: 108–18.

Retrospective case series of 155 cases failed to reveal any cases of basal cell carcinoma. Trichoblastoma was the most common (7.7%) basaloid tumor. It appears that histologic misinterpretation of trichoblastomas as basal cell carcinomas has been responsible for the erroneous reporting of an increased risk of basal cell carcinoma

development within nevus sebaceus. The authors concluded that early prophylactic surgery seems inappropriate.

Secondary neoplasms associated with nevus sebaceus of Jadassohn: a study of 707 cases

Idriss MH, Elston DM. J Am Acad Dermatol 2014; 70: 332–7.

Retrospective case series of 706 cases demonstrating that most secondary neoplasms arising in association with nevus sebaceus are benign. Trichoblastoma and syringocystadenoma papilliferum were the most frequent benign tumors, occurring in 7.4% and 5.2% of cases, respectively. Malignant tumors were present in 2.5% of the cases, with basal cell carcinoma being most common, and almost all were seen in adults. The authors conclude that it is reasonable to delay surgical management until adolescence.

Specific Intervention

- Skin biopsy

A skin biopsy may be performed to confirm a clinical diagnosis. Clinical changes suggestive of neoplastic transformation may be investigated by skin biopsy.

First-Line Therapies

• Observation	D
• Surgical excision	E

Based on recent case series and histologic analyses that demonstrate the incidence of basal carcinoma is rare, particularly in children, clinical observation should be considered as the first option for any intervention. Prophylactic surgical excision is not warranted based on current data. Elective surgical excision may be considered if

lesions become symptomatic or affect appearance. In instances of biopsy-confirmed neoplastic transformation, management should be dictated by the histology of the specific tumor.

Nevus sebaceous revisited

Moody MN, Landau JM, Goldberg LH. *Pediatr Dermatol* 2012; 29: 15–23.

A comprehensive review of reported nevus sebaceus outcomes and recommendations for prophylactic excision are provided. It is recommended that all cases of nevus sebaceus be evaluated individually with a thorough medical history, physical examination, and review of therapeutic options in order to determine if prophylactic excision is warranted. Nevus sebaceus in cosmetically apparent regions in healthy children is recognized as a reasonable indication for consideration of prophylactic excision.

Second-Line Therapies

• Curettage and cautery	E
• Cryotherapy	E
• Laser resurfacing	E
• Photodynamic therapy	E

A variety of destructive methods have been described for treatment of nevus sebaceus and provide an alternative to surgical excision; however, they may not be as effective in removal of deeper structures.

Linear nevus sebaceus of Jadassohn treated with the carbon dioxide laser

Ashinoff R. *Pediatr Dermatol* 1993; 10: 189–91.

A case report of the use of a carbon dioxide laser to electively treat a nevus sebaceus of the nose in a 10-year-old boy. Carbon dioxide laser vaporization provided partial and superficial destruction with good palliative appearance-enhancing result. The treatment did not eliminate the need for continued clinical surveillance.

Topical photodynamic therapy for nevus sebaceous on the face

In S-I, Lee JY, Kim YC. Eur J Dermatol 2010; 20: 590–2.

A total of 12 patients were treated with topical 20% aminolevulinic acid (ALA) or methyl aminolevulinate (MAL) after CO₂ laser ablation. Lesions were irradiated with a light-emitting diode (LED) device. Treatment was repeated at 1- to 4-week intervals to each patient. All 12 patients responded with 3/12 (25%) mild (25%–50% improvement), 7/12 (58%) moderate (51%–75% improvement), and 2/12 (17%) marked (>75%) improvement. Two patients showed partial recurrences after completion of treatments. There were no significant side effects.

Notalgia paresthetica

Joanna Wallengren

Notalgia paresthetica is a unilateral sensory neuropathy characterized by pruritus or burning pain at the medial inferior tip of the scapula. Accompanying pigmentation or mild lichenification is secondary to scratching. Occasionally the distribution may be bilateral, and a few hereditary cases have been described. Pruritus is believed to result from nerve impingement or chronic nerve trauma.

Management Strategy

Treatment aims to reduce the itch by altering peripheral or central

nerve transmission. Topical corticosteroids are generally ineffective unless secondary inflammation is present.

Topical *capsaicin* 0.025% three times daily for 5 weeks depletes sensory nerve transmitters in the skin. In case of relapse, the treatment may be repeated for a few days or weeks until pruritus subsides. Capsaicin may be applied in higher concentrations such as 0.075% or 0.1%; with increasing concentrations there is more burning but the desensitization of the skin occurs sooner. High-dose (8%) capsaicin patch for 1 hour is associated with severe burning. It has shown considerable variability in efficacy, reducing notalgia paresthetica for 2 days to 3 months.

Local anesthesia with 5% lidocaine patch twice daily blocks peripheral nerve transmission, but there is a risk for contact allergy to the anesthetic.

Daily electrical stimulation using *cutaneous field stimulation (CFS)* or *transcutaneous electrical nerve stimulation (TENS)* for 2 to 5 weeks has been tried with good results, with the pruritus relapsing gradually.

Deep intramuscular *acupuncture* to the paravertebral muscles in the T2 to T6 dermatome once a week until the pruritus subsides, as well as spinal physiotherapy, has been reported in a few cases. Also, single treatments with *botulinum toxin* or an *anesthetic block* have been described in anecdotal case reports. The reduction of itch due to these treatments may last for months or years.

Oral therapy may be preferred in patients in whom repeated topical treatments may be difficult to perform. Anticonvulsants such as *gabapentin* or *oxcarbazepine* alter central nerve transmission. Gabapentin in doses of 900 mg a day is often required.

Most of these treatments offer only transient relief, and there is a considerable risk of relapse upon discontinuation of treatment.

Specific Investigations

- Skin biopsy
- Radiography of the thoracic spine
- Magnetic resonance imaging (MRI) of the thoracic spine

Notalgia paresthetica. Case reports and histologic appraisal

Weber PJ, Poulos EG. J Am Acad Dermatol 1988; 18: 25–30.

Skin biopsies from 14 patients revealed necrotic keratinocytes.

Melanin and melanophages in the upper and mid-dermis were found in biopsies of patients with pigmented lesions.

Investigation of spinal pathology in notalgia paresthetica

Savk O, Savk E. J Am Acad Dermatol 2005; 52: 1085–7.

Forty-three patients with notalgia paresthetica underwent radiography of the spine. Thirty-seven skin lesions were accompanied by relevant spinal changes (60.7%).

Notalgia paresthetica associated with nerve root impingement

Eisenberg E, Barmeir E, Bergman R. J Am Acad Dermatol 1997; 37: 998–1000.

An impingement of the nerve root was confirmed by MRI in one patient.

Notalgia paresthetica is a clinical diagnosis, and none of the previously mentioned investigations are required in the clinical situation.

First-Line Therapies

• Capsaicin 0.025%	A
• Lidocaine 5% patch	E

Successful treatment of notalgia paresthetica with topical capsaicin: vehicle-controlled, double-blind, crossover study

Wallengren J, Klinker M. J Am Acad Dermatol 1995; 32: 287–9.

This double-blind crossover comparison between capsaicin 0.025% and vehicle cream was performed in 20 patients for 10 weeks, with the 4-week treatments being followed by 2 weeks of washout. The group treated with capsaicin first had a reduction of VAS (Visual Analog Scale) from 61% to 35% during the first period, whereas in the other group VAS was reduced from 52% to 27%. Most patients relapsed within a month.

Notalgia paraesthetica—report of three cases and their treatment

Layton AM, Cotterill JA. Clin Exp Dermatol 1991; 16: 197–8.

All three patients improved upon treatment with 2.5% lidocaine and 2.5% prilocaine; two patients relapsed, but pruritus was reduced.

Second-Line Therapies

• Cutaneous field stimulation	D
• TENS	D
• Gabapentin	E
• Oxcarbazepine	E

Cutaneous field stimulation (CFS) in treatment of severe localized itch

Wallengren J, Sundler F. Arch Dermatol 2001; 137: 1323–5.

Seventeen patients with different disorders of neuropathic pruritus completed the study. Four of five patients with notalgia paresthetica improved after daily use of CFS for 5 weeks, with VAS reduced from 65% to 40%. Itch gradually relapsed after the discontinuation of CFS.

Transcutaneous electrical nerve stimulation offers partial relief in notalgia paresthetica patients with a relevant spinal pathology

Savk E, Savk O, Sendur F. J Dermatol 2007; 34: 315–9.

Nine of 15 patients treated with TENS for 2 weeks improved substantially, with mean VAS being reduced from 100% to 45%.

Efficacy of gabapentin in the improvement of pruritus and quality of life of patients with notalgia paresthetica

Maciel AA, Cunha PR, Laraia IO, Trevisan F. An Bras Dermatol 2014; 89: 570–5.

A nonrandomized study of 20 patients, where 10 patients were

treated with gabapentin 300 mg/day for 4 weeks. At the end of treatment, mean VAS for pruritus was decreased from 95% to 50%.

Open pilot study on oxcarbazepine for the treatment of notalgia paresthetica

Savk E, Bolukbasi O, Akyol A, Karaman G. J Am Acad Dermatol 2001; 45: 630–2.

Four patients were treated with oxcarbazepine for 6 months: two improved, with VAS reduced from 80% to 50% and from 90% to 40%, respectively.

Third-Line Therapies

• Spinal physiotherapy with ultrasound and manipulation	D
• Botulinum toxin A	D
• Acupuncture (deep intramuscular stimulation) of the paravertebral muscles at T2–T6 once a week until pruritus subsides	E
• Anesthetic paravertebral block at dermatome T3–T6 with bupivacaine 0.75% and methylprednisolone on one occasion	E

Notalgia paresthetica: clinical, physiopathological and therapeutic aspects. A study of 12 cases

Raison-Peyron N, Meunier L, Acevedo M, Meynadier J. J Eur Acad Dermatol Venereol 1999; 12: 215–21.

Pruritus was reduced in four of six patients treated by spinal physiotherapy using ultrasound or manipulation. The improvement was sustained for 1 to 9 years.

Botulinum toxin type A for neuropathic itch

Wallengren J, Bartosik J. Br J Dermatol 2010; 163: 424–6.

Four patients with notalgia paresthetica received a total of 18 to 100 U of BTX-A (Botulinum toxin A) intradermally to the affected area. Mean VAS was reduced by 40% at 6-week follow-up. At follow-up after 18 months, pruritus relapsed.

Treatment of notalgia paresthetica with botulinum toxin A: a double-blind randomized controlled trial

Maari C, Marchessault P, Bissonnette R. J Am Acad Dermatol. 2014;70(6):1139–41.

In this double-blind, randomized, placebo-controlled study on 20

patients with notalgia paresthetica, a total dose of up to 200 U BTX-A or saline was administered intradermally. After an observation of 12 weeks after the treatment, the placebo group received BTX-A, and both groups were evaluated at week 24. There was no statistically significant difference between the patients treated with BTX-A and placebo.

Neurogenic pruritus: an unrecognised problem? A retrospective case series of treatment by acupuncture

Stellon A. *Acupunct Med* 2002; 20: 186–90.

Sixteen patients with different disorders of neuropathic pruritus completed the study. Four patients with notalgia paresthetica improved, with mean VAS reduced from 73% to 0%.

Successful treatment of notalgia paresthetica with a paravertebral local anesthetic block

Goulden V, Toomey PJ, Highet AS. *J Am Acad Dermatol* 1998; 8: 114–6.

Paravertebral block at dermatome T3 to T6 in one patient resulted in clearing of pruritus within a few days, lasting for 1 year of follow-up.

Onchocerciasis

Michele E. Murdoch

Onchocerciasis is a major tropical parasitic infection caused by the filarial worm *Onchocerca volvulus* and is transmitted by blood-sucking *Simulium* spp. blackflies, which breed near fast-flowing rivers. Global estimates suggest that 37 million people carry *O. volvulus*, most of whom live in Africa, and a total of 120 million people are considered at risk of infection because of where they live. The disease is endemic in 30 countries in sub-Saharan Africa, and small foci also exist in Yemen and Central and Southern America. Mass ivermectin treatment has now eliminated or interrupted transmission in 11 of the

13 foci in the Americas, and the World Health Organization has verified elimination of onchocerciasis in Colombia, Ecuador, Mexico and Guatemala. The first manifestation of infection is usually intense pruritus, and subsequently a wide variety of acute and chronic skin and eye changes develop. The socioeconomic consequences of onchocerciasis are most marked in hyperendemic areas in sub-Saharan Africa. Globally, approximately 270,000 people are blind and 500,000 have significant visual loss as a direct consequence of onchocerciasis. A multicountry study in Africa revealed that 42% of the adult population in endemic villages suffered from pruritus, and 28% of the population had onchocercal skin lesions.

Management Strategy

The mainstay of treatment is *ivermectin*. Ivermectin is a safe, effective microfilaricide (i.e., it kills the immature larval stages of filarial worms), but it does not kill the adult worms. After a few months of dosing, the numbers of microfilariae in the skin gradually increase back toward pretreatment levels, and treatment has to be repeated throughout the lifespan of the adult worm (10–14 years).

Wolbachia spp. symbiotic endobacteria have been identified as essential for the filarial worms' fertility and offer novel targets for treatment. Additional treatment with *doxycycline* to sterilize the worms significantly enhances ivermectin-induced suppression of microfilaridermia.

The approach to treatment of onchocerciasis varies for (1) treatment of individuals outside of endemic areas, (2) treatment of individuals within endemic areas, and (3) mass treatment programs.

Treatment of Individuals Outside of Endemic Areas

Treatment of individuals living outside of areas with ongoing transmission consists of a single dose of ivermectin (150 µg/kg), followed 1 week later by doxycycline (200 mg daily for 6 weeks). Alternative doxycycline regimens are doxycycline 200 mg daily for 4 weeks or 100 mg daily for 6 weeks.

If the patient is pregnant or less than 9 years of age, doxycycline is contraindicated.

Treatment of Individuals Within Endemic Areas

Treatment of individuals within areas of ongoing transmission consists of a single dose of ivermectin 150 µg/kg repeated every 3 to 6 months until the patient is asymptomatic. Treatment should be repeated if there is recurrence of pruritus, itchy papular rash, or eosinophilia. Treatment with ivermectin may be required for 10 years or more.

Mass Treatment Programs

Three regional programs have been established to coordinate global control. The Onchocerciasis Control Program (OCP, 1974–2002) successfully used *aerial larviciding* of rivers in West Africa to control the vector blackfly, and more recently it has distributed *ivermectin* to control any recrudescence. The Onchocerciasis Elimination Program in the Americas (OEPA), which started in 1991, uses 6-monthly mass ivermectin therapy and aims to eliminate onchocerciasis from the region. The largest program, the African Program for Onchocerciasis Control (APOC), commenced in 1995 and aims to eliminate onchocerciasis by 2025. It consists of large-scale, annual, community-directed treatment of ivermectin in 15 non-OCP countries and 4 ex-OCP countries. Its original aim was to reduce onchocerciasis until it was no longer a public health problem, but this was revised in 2010 to aim for elimination.

In forested areas of central Africa and Sudan, which are coendemic with loiasis, ivermectin cannot be used because it causes serious neurologic adverse reactions, including encephalopathy. Whereas lengthy doxycycline regimens are deemed impractical for main large-scale treatment of onchocerciasis, in areas coendemic with loiasis, doxycycline is a safe alternative as it is inactive against *Loa loa* because of the absence of *Wolbachia*.

Specific Investigations

- Skin snips
- Other parasitologic forms of diagnosis:
 - Detection of intraocular microfilariae using a slit lamp
 - Demonstration of adult worms by collagenase digestion of

excised nodules

- Full blood count (for eosinophilia)
- Mazzotti test (only do if skin snips negative and hence patient likely to be lightly infected)
- Future investigative tools:
 - Diethylcarbamazine patch test
 - Serodiagnosis
 - Polymerase chain reaction
 - Antigen detection dipstick assay on urine

First-Line Therapies

• Ivermectin	A
• Ivermectin combined with doxycycline	A

The effects of ivermectin on onchocercal skin disease and severe itching: results of a multicentre trial

Brieger WR, Awedoba AK, Eneanya CI, Hagan M, Ogbuagu KF, Okello DO et al. Trop Med Int Health 1998; 3: 951–61.

The effects of ivermectin were assessed in 3-monthly, 6-monthly, and annual doses in 4072 villagers in forest zones of Ghana, Nigeria, and Uganda who underwent interviews and clinical examinations at baseline and at five follow-up visits. Reactive skin lesions were categorized as acute papular onchodermatitis, chronic papular onchodermatitis, and lichenified onchodermatitis. From 6 months onwards there was a 40% to 50% reduction in the prevalence of severe itching after ivermectin treatment compared with the placebo group. Also, a greater reduction in prevalence and severity of reactive skin lesions over time was seen in those receiving ivermectin. The differences between the various ivermectin treatment regimens were not significant.

The African Programme for Onchocerciasis Control: impact on onchocercal skin disease

Ozoh GA, Murdoch ME, Bissek A-C, Hagan M, Ogbuagu K, Shamad

M et al. *Trop Med Int Health* 2011; 16: 875–83.

Seven study sites in Cameroon, Sudan, Nigeria, and Uganda participated in two cross-sectional surveys of 5193 individuals at baseline and 5180 people after 5 or 6 years of annual ivermectin therapy. At follow-up, significant ($p < 0.001$) reductions were found in the risk of itching (odds ratio [OR] 0.32) and acute papular onchodermatitis (OR 0.28), chronic papular onchodermatitis (OR 0.34), depigmentation (OR 0.31), and nodules (OR 0.37). Reduction in the odds ratio of lichenified onchodermatitis was also significant (OR 0.54, $p < 0.03$).

A trial of a three-dose regimen of ivermectin for the treatment of patients with onchocerciasis in the UK

Churchill DR, Godfrey-Faussett P, Birley HDL, Malin A, Davidson RN, Bryceson ADM. *Trans R Soc Trop Med Hyg* 1994; 88: 242.

As ivermectin is also thought to suppress embryogenesis in adult worms, the efficacy of three doses of ivermectin given at monthly intervals was studied to determine whether such a regimen could lead to a greater suppression of microfilaridermia. Thirty-three patients (of whom 27 were European) with onchocerciasis were treated with a single dose of 150 to 200 µg/kg ivermectin and observed in hospital for 72 hours. Second and third doses were given as outpatient treatment, respectively, 1 and 2 months later. Patients were followed up at 3-, 6-, and 12-monthly intervals after the last dose of ivermectin. The patients with positive skin snips before treatment were compared with patients given a single dose of ivermectin in a previous study (Godfrey-Faussett P et al., 1991, see later). Relapses occurred slightly less frequently after three doses. In contrast to studies in West Africa, where reactions to ivermectin are rare, 17 patients (52%) had reactions. The authors therefore recommend that the first dose of ivermectin for lightly infected expatriates be given in hospital.

Ivermectin in the treatment of onchocerciasis in Britain

Godfrey-Faussett P, Dow C, Black ME, Bryceson ADM. *Trop Med Parasitol* 1991; 42: 82–84.

Thirty-one patients with early, light infection were treated with a single dose of 150 to 200 µg/kg ivermectin. Those who relapsed were retreated after an interval of not less than 5 months. Approximately two thirds relapsed within 1 year. A similar pattern was seen after the

second dose. A single dose of ivermectin, repeated every 3 to 6 months as necessary, was considered to be the treatment of choice for patients in nonendemic areas lightly infected with *O. volvulus*. One third of such patients may be cured with each treatment.

Effects of standard and high doses of ivermectin on adult worms of *Onchocerca volvulus*: a randomised controlled trial

Gardon J, Boussinesq M, Kamgno J, Gardon-Wendel N, Demanga-Ngangue, Duke BOL. Lancet 2002; 360: 203–10.

Ivermectin 150 µg/kg given at intervals of 0.5 to 3.0 months is known to cause slight but significant increased mortality of adult worms. In this randomized study of 657 Cameroonian patients with onchocerciasis, 3-monthly treatment with ivermectin killed more female adult worms than did annual treatment. There was no difference between standard (150 µg/kg) and high-dose schedules (800 µg/kg).

The feasibility of large-scale 3-monthly ivermectin treatment in endemic areas and its likely greater effect in reducing transmission have still to be determined.

An investigation of persistent microfilaridermias despite multiple treatments with ivermectin, in two onchocerciasis-endemic foci in Ghana

Awadzi K, Boakye DA, Edwards G, Opoku NO, Attah SK, Osei-Atweneboana MY et al. Ann Trop Med Parasitol 2004; 98: 231–49.

Some individuals in endemic areas have persistent microfilaridermia despite nine treatments with ivermectin. In this open, case-control study of 21 “suboptimal” responders, 7 amicrofilaridermic responders and 14 ivermectin-naïve subjects, the results revealed that the persistent microfilaridermias are mainly due to nonresponsiveness of the adult female worms, raising the possibility that the worms have developed resistance to ivermectin.

Endosymbiotic bacteria in worms as targets for a novel chemotherapy in filariasis

Hoerauf A, Volkmann L, Hamelmann C, Adjei O, Autenrieth IB, Fleischer B et al. Lancet 2000; 355: 1242–43.

The activity of doxycycline against *Wolbachia* spp. and the fertility of adult female worms were assessed by examination of excised subcutaneous onchocercal nodules in 22 Ghanaian individuals treated

with doxycycline 100 mg daily for 6 weeks and 14 untreated controls. Immunohistology with an antibody to bacterial heat shock protein-60 was used to assess the presence or absence of *Wolbachia* spp., and the morphology of female worms was examined. In addition, PCR reactions using, first, endobacterial primers, and, second, nematode primers, were performed. None of the treated worms had usual bacterial loads, and there was total suppression of normal embryonic worm development during early oocyte/morula stages, whereas nodules from untreated controls showed normal embryogenesis.

Depletion of *Wolbachia* endobacteria in *Onchocerca volvulus* by doxycycline and microfilaridermia after ivermectin treatment

Hoerauf A, Mand S, Adjei O, Fleischer B, Büttner DW. Lancet 2001; 357: 1415–16.

The Ghanaian participants in this study were not randomized because this was not acceptable to the village elders. Instead, the first 55 patients were allocated to ivermectin and doxycycline and the next 33 to ivermectin alone. Doxycycline 100 mg daily was given from the start of the study for 6 weeks. Subgroup A (31 doxycycline-treated and 24 controls) was given ivermectin 2.5 months after the start of the study, and subgroup B (24 doxycycline-treated and 9 controls) 6 months after the onset of the study. The results suggested a complete block in worm embryogenesis for at least 18 months after treatment with ivermectin and doxycycline.

The principle of targeting Wolbachia spp. with ivermectin in combination treatment offers the potential of interrupting transmission. Shorter anti-Wolbachia spp. regimens (either with other antibiotics or in combinations) are needed for mass treatment of endemic areas.

***Wolbachia* endobacteria depletion by doxycycline as antifilarial therapy has macrofilaricidal activity in onchocerciasis: a randomized placebo-controlled study**

Hoerauf A, Specht S, Büttner M, Pfarr K, Mand S, Fimmers R et al. Med Microbiol Immunol 2008; 197: 295–311.

In a randomized, placebo-controlled trial in Ghana, 67 onchocerciasis patients received 200 mg/day doxycycline for 4 or 6 weeks, followed by ivermectin after 6 months. After 6, 20, and 27 months, efficacy was evaluated by onchocercoma histology, PCR, and microfilariae determination. Administration of doxycycline resulted in endobacteria depletion and female worm sterilization. The 6-week

treatment was macrofilaricidal, with >60% of the female worms found dead.

Macrofilaricidal activity after doxycycline only treatment of *Onchocerca volvulus* in an area of *Loa loa* co-endemicity: a randomized controlled trial

Turner JD, Tendongfor N, Esum M, Johnston KL, Langley RS, Ford L et al. PLoS Negl Trop Dis 2010; 4: e660.

Within a larger, double-blind, randomized trial, a group of 22 Cameroonian individuals coinfectd with *O. volvulus* and low to moderate intensities of *L. loa* infection were treated with a course of 6 weeks of doxycycline 200 mg/day followed by ivermectin at 4 months. Doxycycline was well tolerated in patients coinfectd with moderate intensities of *L. loa* microfilariae. A 6-week course of doxycycline yielded macrofilaricidal and worm-sterilizing effects, which were not dependent on coadministration of ivermectin.

Long term impact of large scale community-directed delivery of doxycycline for the treatment of onchocerciasis

Tamarozzi F, Tendongfor N, Enyong PA, Esum M, Faragher B, Wanji S et al. Parasites Vectors 2012; 5: 53.

In an area coendemic for *O. volvulus* and *L. loa*, 375 Cameroonian individuals who had been treated 4 years previously with doxycycline 100 mg daily for 6 weeks followed by one or two rounds of annual ivermectin mass drug treatment, plus 132 persons who had had one or two rounds of annual ivermectin alone, were evaluated. A statistically significant lower microfilarial prevalence and load were found in those who had received doxycycline followed by ivermectin compared with those who received ivermectin alone.

Second-Line Therapies

• Albendazole

A

Albendazole in the treatment of onchocerciasis: double-blind clinical trial in Venezuela

Cline BL, Hernandez JL, Mather FJ, Bartholomew R, De Maza SN, Rodulfo S et al. Am J Trop Med Hyg 1992; 47: 512–20.

Forty-nine individuals with onchocerciasis (26 treated and 23 controls) were treated with a 10-day course of albendazole (400 mg daily) or placebo. Patients in the albendazole-treated group with baseline microfilarial densities over 5 mf/mg skin showed a significant reduction in microfilarial densities at 12 months. Albendazole was well tolerated and is believed to interfere with embryogenesis in adult *O. volvulus* worms.

The co-administration of ivermectin and albendazole – safety, pharmacokinetics and efficacy against *Onchocerca volvulus*

Awadzi K, Edwards G, Duke BOL, Opoku NO, Attah SK, Addy ET et al. Ann Trop Med Parasitol 2003; 97: 165–78.

In a randomized, double-blind, placebo-controlled trial in 44 male patients with onchocerciasis in Ghana, the coadministration of ivermectin (200 µg/kg) with albendazole (400 mg) did not offer any advantage over ivermectin alone.

N.B. Onchocerciasis and lymphatic filariasis commonly coexist, and current integrated control programs use repeated annual mass treatment of endemic communities with ivermectin and albendazole.

Other therapies

• Suramin	D
• Future therapies • Moxidectin • New macrofilaricides	A

Thirty-month follow-up of sub-optimal responders to multiple treatments with ivermectin, in two onchocerciasis-endemic foci in Ghana

Awadzi K, Attah SK, Addy ET, Opoku NO, Quartey BT, Lazdins-Helds JK et al. Ann Trop Med Parasitol 2004; 98: 359–70.

Suramin is both a macrofilaricide and a microfilaricide, but unfortunately a course of suramin requires weekly intravenous

infusions and may have serious adverse effects, including nephrotoxicity.

In this paper, Awadzi et al. propose the use of suramin under hospital supervision in selected individuals with onchocerciasis who are resistant to multiple doses of ivermectin. The treatment regimen proposed was a total adult dose of 5.0 g (72.5–84.7 mg/kg) over 6 weeks.

Report of the 36th session of the Technical Consultative Committee (TCC), Ouagadougou, 11–15 March, 2013

World Health Organization/African Programme for Onchocerciasis Control (APOC).

http://www.who.int/apoc/about/structure/tcc/TCC36_Final_Report_17 (accessed 23/3/16).

Moxidectin is a microfilaricidal drug that shows a higher potency than ivermectin in animal models. A phase III trial in humans in 1472 people aged 12 years and above in four study sites in Ghana, Liberia, and the Democratic Republic of Congo compared a single dose of 8 mg moxidectin with ivermectin (150 µg/kg). A reported 96.6% of moxidectin-treated and 97.2% of ivermectin-treated individuals completed 12 months follow-up. Preliminary results revealed that the average percent reduction in skin mf levels during 1-year posttreatment was significantly higher after moxidectin (95.0 ± 1.9) than ivermectin (84.4 ± 15.4). Moxidectin had a higher and more prolonged efficacy compared with ivermectin. Because moxidectin has the same mode of action as ivermectin, whether it could replace ivermectin in the event of resistance is unknown.

After an investment from the Global Health Investment Fund (GHIF) in 2015, Medicines Development for Global Health has commenced the registration process for moxidectin for human use.

In addition to being one of the sponsors for GHIF, the Bill & Melinda Gates Foundation is also supporting research to optimize other treatment regimens (Death of Onchocerciasis and Lymphatic Filariasis, DOLF; www.dolf.wustl.edu). Studies include attempts to reformulate flubendazole, a known effective macrofilaricide, in order to improve its bioavailability.

Oral lichen planus

Drore Eisen

Oral lichen planus (OLP) is a common chronic inflammatory disorder affecting all areas of the oral mucosa that rarely undergoes complete remission, even with treatment.

Management Strategy

All treatment should be aimed at eliminating erythematous and ulcerative lesions, alleviating symptoms, and potentially reducing the risk of malignant transformation. Given the uncertainty of the premalignant nature of OLP, it is important to monitor all patients carefully and long term.

Although the etiology of OLP is unknown, the possibility of a hypersensitivity reaction (oral lichenoid reaction) should be considered when lesions are confined to mucosa in close proximity to a dental restoration. In such cases, identifying allergies to dental materials by patch testing and then removing the fillings with positive reactions or empirically removing the filling often results in resolution. Another uncommon cause of lichenoid reaction is drugs. A thorough medication history, with emphasis on nonsteroidal antiinflammatory drugs (NSAIDs) and angiotensin-converting enzyme (ACE) inhibitors is warranted, as drug-induced reactions are reversible when the implicated drug is withdrawn.

Exacerbating factors, including sharp dental restorations and poorly fitting dental appliances, should be eliminated. An optimal oral hygiene program that minimizes dental plaque and calculus can significantly improve gingival OLP.

All agents employed for the treatment of OLP are for off-label indications and lack adequate efficacy studies; thus optimal dose, duration of treatment, safety, and their true efficacy remain unknown.

The most useful agents for the treatment of OLP are *potent topical corticosteroids*. Asymptomatic reticular lesions do not require therapy. For intractable erosive lesions, *intralesional corticosteroids* repeated every 2 to 4 weeks are highly effective.

Unresponsive OLP may benefit from *topical immunomodulators* (i.e., tacrolimus, pimecrolimus, and ciclosporin), which may be used as alternatives to, or in conjunction with, topical corticosteroids. Relapses after cessation of therapy are to be expected. Their long-term safety for this chronic disease is unknown.

A number of *herbal preparations* have been reported to benefit OLP, including curcuminoids (6000 mg/d), lycopene (8 mg/day), and

topical aloe vera (70% concentration).

A variety of *lasers, UV phototherapy, and photodynamic therapy* have also been shown to be beneficial in alleviating OLP symptoms.

For patients with severe oral disease or with extraoral manifestations, the addition of *systemic immunosuppressives* is indicated. The author has found that methotrexate (12.5–20 mg/week), azathioprine (100–150 mg/day), mycophenolate mofetil (1–2 g/day), acitretin (25–50 mg/day), and hydroxychloroquine (400 mg/day) are the most useful systemic agents. Cyclosporin, thalidomide, and Tumor necrosis factor-alpha (TNF- α) inhibitors may be used for refractory cases, but data are limited.

Systemic corticosteroids (30–80 mg of prednisone) should be reserved for acute flares and not as maintenance therapy. Secondary candidiasis frequently complicates all therapies and requires treatment with topical or systemic agents. All treatments for OLP are palliative and not curative, and patients should expect a chronic course with intermittent acute exacerbations.

Specific Investigations

- Biopsy for confirmation; direct immunofluorescence when indicated to exclude vesiculoerosive diseases
- Monitoring for malignant transformation
- Hepatitis serologies when risk factors are present
- Thyroid disease may constitute a comorbidity of OLP
- Consider contact and drug lichenoid reactions

Direct immunofluorescence in oral lichen planus

Buajeeb W, Okuma N, Thanakun S, Laothumthut T. JCDR 2015; 9: ZC34–7.

Biopsies of gingival OLP are often nondiagnostic. Immunofluorescence shows characteristic shaggy fibrinogen deposition at the basement membrane zone.

The malignant transformation of oral lichen planus and oral lichenoid lesions: a systematic review

Fitzpatrick SG, Hirsch SA, Gordon SC. J Am Dent Assoc 2014; 145: 45–56.

Although the malignant potential of OLP remains controversial, the

overall rate of transformation approximates 1%, requiring continued regular observation of patients.

Course of oral lichen planus: a retrospective study of 808 northern Italian patients

Carbone M, Arduino PG, Carrozzo M, Gandolfo S, Argiolas MR, Bertolusso G, et al. Oral Dis 2009; 15: 235–43.

Routine hepatitis screening in northern European and American OLP patients without risk factors may not be warranted, but OLP is significantly associated with hepatitis C infections in southern Europe and Japan.

Association between oral lichenoid reactions and amalgam restorations

Pezelj-Ribaric S, Prpic J, Miletic I, Brumini G, Soskic MS, Anic I. J Eur Acad Dermatol Venereol 2008; 22: 1163–7.

When patch test reactions to mercury compounds were positive, partial or complete replacement of amalgam fillings led to a significant improvement in nearly all patients.

Thyroid disease and oral lichen planus as comorbidity: a prospective case-control study

Garcia-Pola MJ, Llorente-Pendas S, Seoane-Romero JM, Berasaluce MJ, Garcia-Martin JM. Dermatology 2016 [Epub ahead of print].

Diagnosis of thyroid disease was present in 15.3% of 215 OLP patients.

First-Line Therapies

• Topical corticosteroids	B
• Intralesional corticosteroids	B

Systemic and topical corticosteroid treatment of oral lichen planus: a comparative study with long-term follow-up

Carbone M, Goss E, Carrozzo M, Castellano S, Conrotto D, Broccoletti

R, et al. J Oral Pathol Med 2003; 32: 323–9.

Patients treated with either topical clobetasol or prednisone and then clobetasol responded similarly, suggesting that prednisone should be reserved only for acute exacerbations.

High-potency preparations are more effective than midpotency ones. Once the disease becomes controlled, topical steroids may be used several times weekly to prevent flare-ups.

Efficacy of intralesional betamethasone for erosive oral lichen planus and evaluation of recurrence: a randomized, controlled trial

Liu C, Xie B, Yang Y, Lin D, Wang C, Lin M, et al. Oral Surg Oral Med Oral Pathol Oral Radiol 2013; 116: 584–90.

Intralesional triamcinolone and betamethasone are highly efficacious for erosive lesions.

Second-Line Therapies

Topical immunosuppressants

• Tacrolimus	A
• Pimecrolimus	A
• Ciclosporin	A

Systemic immunosuppressants

• Methotrexate	E
• Mycophenolate mofetil	E
• Azathioprine	E
• Hydroxychloroquine sulfate	C
• TNF-alpha inhibitors (adalimumab, etanercept)	E
• Levamisole	C

A comparative treatment study of topical tacrolimus and clobetasol in oral lichen planus

Radfar L, Wild RC, Suresh L. Oral Surg Oral Med Oral Pathol Oral Radiol Endod 2008; 105: 187–93.

In this 6-week, 30-patient study, tacrolimus was shown to be as useful as clobetasol.

Long-term efficacy and safety of topical tacrolimus in the management of ulcerative/erosive oral lichen planus

Hodgson TA, Sahni N, Kaliakatsou F, Buchanan JA, Porter SR. Eur J Dermatol 2003; 13: 466–70.

Of 50 patients who used tacrolimus for 2 to 39 months, 14% had complete resolution of ulcers, 80% had partial resolution, and 6% reported no benefit.

Randomized trial of pimecrolimus cream versus triamcinolone acetonide paste in the treatment of oral lichen planus

Gorouhi, F, Solhpour A, Beitollahi JM, Afshar S, Davari P, Hashemi P, et al. J Am Acad Dermatol 2007; 57: 806–13.

In a 20-patient, 2-month study, pimecrolimus was as effective as triamcinolone 0.1%.

Pimecrolimus 1% cream for oral erosive lichen planus: a 6-week randomized, double-blind, vehicle-controlled study with a 6-week open-label extension to assess efficacy and safety

McCaughey C, Machan M, Bennett R, Zone JJ, Hull CM. J Eur Acad Dermatol Venereol 2011; 25: 1061–7.

Highly effective when used twice daily for 6 weeks, but blood concentrations were detected in most patients. Relapses occurred in all patients after discontinuing therapy.

Clinical and serologic efficacy of topical calcineurin inhibitors in oral lichen planus: a prospective randomized controlled trial

Vohra S, Singal A, Sharma SB. Int J Dermatol 2016; 55: 101–5.

In an 8-week study involving 40 patients, pimecrolimus and tacrolimus were equally effective.

Tacrolimus and pimecrolimus are not always effective and, when discontinued, do not result in long-term benefits. Given the potential for systemic absorption, their safety for long-term use in the oral cavity remains unknown.

Ciclosporin vs. clobetasol in the topical management of atrophic and erosive oral lichen planus: a double-blind, randomized controlled trial

Conrotto D, Carbone M, Carrozzo M, Arduino P, Broccoletti R, Pentenero M, et al. Br J Dermatol 2006; 154: 139–45.

In this 2-month study, 40 patients (65%) improved with ciclosporin versus 95% with clobetasol. Two months after discontinuing treatment, one third of the clobetasol group remained clear, versus three quarters of the ciclosporin group.

Ciclosporin benefits are inconsistent. The high cost of swishing ciclosporin (500 mg/5 mL TID) limits its use, but swishing a smaller quantity or applying a finger rub dose (50 mg/day) has been shown to be beneficial and lowers the cost.

Oral lichen planus: a case series with emphasis on therapy

Torti DC, Jorizzo JL, McCarty MA. Arch Dermatol 2007; 143: 511–5.

About 50% treated with low doses of methotrexate (2.5–12.5 mg/week) responded to therapy.

Successful treatment of oral erosive lichen planus with mycophenolate mofetil

Dalmau J, Puig L, Roe E, Peramiquel L, Campos M, Alomar A. J Eur Acad Dermatol Venereol 2007; 21: 259–60.

A prospective study of findings and management in 214 patients with oral lichen planus

Silverman S Jr, Gorsky M, Lozada-Nur F, Giannotti K. Oral Surg Oral Med Oral Pathol Oral Radiol Endod 1991; 72: 665–70.

Azathioprine (50–150 mg/day) is effective but requires 3 to 6 months before maximal benefit is achieved.

Hydroxychloroquine sulfate (Plaquenil) improves oral lichen planus: an open trial

Eisen D. J Am Acad Dermatol 1993; 28: 609–12.

Nine out of 10 patients had an excellent response to hydroxychloroquine 200 to 400 mg/d for 6 months.

Adalimumab in the management of cutaneous and oral lichen planus

Chao TJ. Cutis 2009; 84: 325–8.

A single case report of “thick plaques” of lichen planus arising on the tongue and buccal mucosa responding to adalimumab.

Etanercept for the management of oral lichen planus

Yarom N. Am J Clin Dermatol 2007; 8: 121.

Levamisole monotherapy for oral lichen planus

Won TH, Park SY, Kim BS, Seo PS, Park SD. Ann Dermatol 2009; 21: 250–4.

In 11 patients taking levamisole 50 mg three times daily for three consecutive days per week, after 3 months, 5 patients reported complete improvement.

Although systemic agents offer significantly better results than topicals, none produces long-term remission when discontinued. Clinical benefits are achieved and maintained with long-term administration, and topicals should be administered concomitantly.

Third-Line Therapies

• Topical and systemic retinoids	B
• Systemic ciclosporin	D
• Thalidomide	E
• Curcuminoids	C
• Lycopene	C
• Aloe vera gel	B
• Lasers, UV phototherapy, photodynamic therapy	B

Topical tretinoin therapy and oral lichen planus

Sloberg K, Hersle K, Mobacken H, Thilander H. Arch Dermatol 1979; 115: 716–8.

More than 70% of the 23 patients treated with 0.1% tretinoin improved.

Topical retinoids in oral lichen planus treatment: an overview

Petruzzi M, Lucchese A, Lajolo C, Campus G, Lauritano D, Serpico R. Dermatology 2013; 226: 61–7.

As a monotherapy, topical retinoids have limited value and should be used in combination with topical corticosteroids.

Treatment of lichen planus with acitretin: a double-blind, placebo-controlled study in 65 patients

Laurberg G, Geiger JM, Hjorth N, Holm P, Hou-Jensen K, Jacobsen KU, et al. J Am Acad Dermatol 1991; 24: 434–7.

In this 2-month study with 65 patients, some with OLP, acitretin (30 mg/day) resulted in remission or marked improvement in most cases. The majority of patients experienced adverse effects.

Efficacy and safety of oral alitretinoin in severe oral lichen planus – results of a prospective pilot study

Kunz M, Urosevic-Maiwald M, Goldinger SM, Frauchiger AL, Dreier J, Belloni B, et al. JEADV 2016; 30: 293–8.

In this study 30 mg oral alitretinoin for 24 weeks in 10 refractory patients resulted in improvement in 40% of patients.

Severe lichen planus clears with very low-dose cyclosporine

Levell NJ, Munro CS, Marks JM. Br J Dermatol 1992; 127: 66–7.

In this study ciclosporin 1 to 2.5 mg/kg/day was used in four patients with extensive disease until skin and oral disease clearance. Relapses could be then controlled with topical therapies on oral ciclosporin discontinuation.

Effective treatment of oral erosive lichen planus with thalidomide

Camisa C, Popovsky JL. Arch Dermatol 2000; 136: 1442–3.

A single report resolving with thalidomide (50–100 mg/d).

High-dose curcuminoids are efficacious in the reduction in symptoms and signs of oral lichen planus

Chainani-Wu N, Madden E, Lozada-Nur F, Silverman S, Jr. J Am Acad Dermatol 2012; 66: 752–60.

In 20 patients in this double-blind placebo study, curcuminoids (6000 mg/d) produced modest benefits.

Lycopene in the management of oral lichen planus: a placebo-controlled study

Saawarn N, Shashikanth MC, Saawarn S, Jirge V, Chaitanya NC, Pinakapani R. Indian J Dent Res 2011; 22: 639–43.

In 15 patients taking lycopene (8 mg/day) for 6 weeks 73% showed 70% to 100% benefit.

Efficacy of topical aloe vera in patients with oral lichen planus: a randomized double-blind study

Salazar-Sanchez N, Lopez-Jornet P, Camacho-Alonso F, Sanchez-Siles M. J Oral Pathol Med 2010; 39: 735–40.

In 32 patients taking a 70% concentration of aloe vera three times a day for 12 weeks most improved modestly.

A comparative pilot study of low intensity laser versus topical corticosteroids in the treatment of erosive-atrophic oral lichen planus

Jajarm HH, Falaki F, Mahdavi O. Photomed Laser Surg 2011; 29: 421–5.

A 630-nm diode laser versus dexamethasone wash was studied in 30 patients; both therapies were effective with equal response rates.

Phototherapy approaches in treatment of oral lichen planus

Pavlic V, Vujic-Aleksic V. Photodermatol Photoimmunol Photomed 2014; 30: 15–24.

This review showed no solid evidence for the effectiveness of UV phototherapy, lasers, or photodynamic therapy for OLP.

Orf

Jane C. Sterling

Orf (ecthyma contagiosum) is due to a parapoxvirus infection and is seen as an inflammatory papule that rapidly evolves to a necrotic blister. Orf usually presents as a single lesion, most commonly on the hands or occasionally the face, but lesions can be multiple or very large in immunosuppressed individuals. The infection is predominantly an occupational disease affecting livestock owners and veterinary workers because the orf virus is carried by sheep and occasionally goats or deer. It has also been reported as a result of animal contact with home husbandry or in association with religious

observances, and there are rare cases of human-to-human transmission.

Management Strategy

Orf is a self-limiting infection, and *treatment is usually not necessary*. The immune response to the virus usually results in resolution of the disease within 2 to 7 weeks without any specific treatment. There is no available treatment that is specifically antiviral for the orf virus, and no human vaccine has been produced. Treatment is usually only indicated if there is secondary bacterial infection or immunosuppression. Erythema multiforme can be triggered by orf infection.

Preventive measures include vaccination of sheep before the lambing period to boost immune response and the wearing of gloves, if possible, when handling animals with any sign of the disease.

Various treatments have been reported anecdotally. *Idoxuridine*, *surgery*, and *cryotherapy* have been suggested to reduce the time to healing. For immunosuppressed individuals, infection with orf may result in a more persistent or progressive infection or giant orf. In such cases, interventional treatment is warranted, and often treatments can be combined. Surgery may be performed to remove the bulk of the infected tissue. Idoxuridine, cryotherapy, *cidofovir*, *interferon*, and topical *imiquimod* cream have been reported to show benefit.

Specific Investigations

- Electron microscopy of scrapings from lesion
- Biopsy
- Polymerase chain reaction (PCR)

Diagnosis is usually clinical but can be confirmed by the noted investigations if required. Electron microscopy is the diagnostic method used in the UK, whereas the Centers for Disease Control and Prevention (CDC) has adopted PCR.

The structure of the orf virus

Nagington J, Newton A, Horne RW. *Virology* 1964; 23: 4611–72.

The ultrastructural description of the orf virus.

Orf. Report of 19 human cases with clinical and pathological observations

Leavell UW, McNamara MJ, Muelling R, Talbert WM, Rucker RC, Dalton AJ. JAMA 1968; 204: 657–64.

Detailed description of clinical and histologic features of 19 cases of orf infection. Defines six stages of infection. Over half the lesions healed within 5 weeks.

Polymerase chain reaction for laboratory diagnosis of orf virus infections

Torfason EG, Gunadottir S. J Clin Virol 2002; 24: 79–84.

Method for molecular diagnosis of orf initially used as research tool but now used in the United States.

Ecthyma contagiosum (orf) – report of a human case from the United Arab Emirates and review of the literature

Al-Salam S, Nowotny N, Sohail MR, Kolodziejek J, Berger TG. J Cutan Pathol 2008; 35: 603–7.

More detailed method for molecular diagnosis of orf used in a clinical case.

First-Line Therapy

- No specific treatment usually necessary

Orf. Report of 19 human cases with clinical and pathological observations

Leavell UW, McNamara MJ, Muelling R, Talbert WM, Rucker RC, Dalton AJ. JAMA 1968; 204: 657–64.

Lymphangitis and lymphadenopathy occurred in 3 of 19 cases.
Awareness of the risk of secondary bacterial infection is important.

Second-Line Therapies

• Surgery	D
• Cryotherapy	D
• Idoxuridine	E
• Cidofovir	E
• Interferon	E
• Imiquimod	D

Giant orf with prolonged recovery in a patient with psoriatic arthritis treated with etanercept

Rørdam OM, Grimstad Ø, Spigset O, Ryggen K. Acta Derm Venereol 2013; 93: 487–8.

During long-term treatment with etanercept, a sheep farmer developed giant orf. He was treated successfully with debulking surgery followed by repeated cryotherapy and imiquimod for a total of 17 weeks.

Orf infection: a clinical study at the Royal Medical Services Hospitals

Tawara MJ, Obaidat NA. J Roy Med Serv 2010; 17: 41–6.

A review of 64 cases observed and treated over 5 years in Jordan. Eleven were treated with cryotherapy and 13 with antibiotics. Most

were treated symptomatically only.

A case of ecthyma contagiosum (human orf) treated with idoxuridine

Hunnskaar S. *Dermatologica* 1984; 168: 207.

The orf lesion of a healthy female was treated with 40% idoxuridine in dimethyl sulfoxide three times daily for 6 days. The lesion healed in less than 4 weeks.

Parapoxvirus orf in kidney transplantation

Peeters P, Sennesael J. *Nephrol Dial Transplant* 1998; 13: 531.

A large lesion on the thumb recurred after excisional surgery. After 40% idoxuridine topically, further surgery, and repeated cryotherapy, the lesion resolved.

Giant orf in a patient with chronic lymphocytic leukaemia

Hunnskaar S. *Br J Dermatol* 1986; 114: 631–4.

A large palmar orf lesion was excised and small local recurrences treated with 40% idoxuridine.

A case of human orf in an immunocompromised patient treated successfully with cidofovir cream

Geerinck K, Lukito G, Snoeck R, DeVos R, DeClercq E, Vanrenterghem Y, et al. *J Med Virol* 2001; 64: 543–9.

An immunosuppressed renal transplant patient developed a persistent giant orf lesion. Treatment with 1% cidofovir cream daily for five cycles of 5 days of treatment alternating with 5 rest days plus debridement as necessary led to full resolution of the lesion.

Recurrent orf in an immunocompromised host

Tan ST, Blake GB, Chambers S. *Br J Plast Surg* 1991; 44: 465–7.

A tumorlike orf lesion in an immunosuppressed patient was unresponsive to surgery and idoxuridine. Temporary improvement occurred after 2 weeks of daily intralesional interferon of 1 million IU per injection with clearance after repeat surgery with subcutaneous interferon (1 million IU daily).

Rapid improvement of human orf (ecthyma contagiosum) with topical imiquimod cream; report of four complicated cases

Erbağci Z, Erbağci I, Almila Tuncel A. *J Dermatolog Treat* 2005; 16:

353–6.

Treatment with imiquimod 5% applied twice daily for up to 10 days to orf lesions complicated by erythema multiforme, angioedema, or as giant orf possibly hastened clearance of the orf lesion and the secondary effects.

Progressive orf virus infection in a patient with lymphoma: successful treatment using imiquimod

Lederman ER, Green GM, DeGroot HE, Dahl P, Goldman E, Greer PW, et al. Clin Infect Dis 2007; 44: e100–3.

Giant and multifocal orf in a patient with non-Hodgkin lymphoma did not respond to debulking and topical cidofovir. Imiquimod 5% cream applied on alternate days led to improvement after a week and clearance within 2 months.

Palmoplantar keratoderma

Ravi Ratnavel

Palmoplantar keratodermas (PPKs) consist of a heterogeneous group of disorders characterized by thickening of the palms and soles. The condition may be subdivided into primary hereditary keratodermas, acquired forms, and conditions in which PPK is an associated secondary feature of a specific dermatosis.

Management Strategy

PPK may be localized to the hands and feet or develop as part of a more generalized skin disorder. It is important when making a diagnosis to establish its morphology and the presence of any associated ectodermal disease at sites other than the palms and soles. Biopsy may be necessary to distinguish between some hereditary forms of PPK. PPK can be associated with infections (dermatophytes,

human papillomavirus, HIV, syphilis, and scabies), drugs (arsenic exposure), and internal malignancy (paraneoplastic phenomenon) or may be a cutaneous manifestation of systemic disease (myxedema, diabetes mellitus). Hyperkeratosis of the palms and soles can also be a feature of eczema, psoriasis, and cutaneous T-cell lymphoma.

Treatment of PPK is challenging. Most therapeutic options produce only short-term improvement and are frequently complicated by unwanted adverse effects. Treatment options range from simple measures such as *saltwater soaks* with physical paring of the skin and use of *topical keratolytics*, through to *systemic retinoids* and *reconstructive surgery* with total excision of the hyperkeratotic skin followed by grafting.

In patients with limited disease, *topical keratolytics* containing salicylic acid, lactic acid, or urea in a suitable emollient base may be tried. Examples include 5% to 10% salicylic acid, 20% to 70% propylene glycol, or 10% lactic acid in aqueous cream or a combination therapy using 10% urea and 5% lactic acid in aqueous cream to be applied twice daily. These formulations can be made up on an individual basis or the closest proprietary product prescribed. The efficacy of these agents may be increased by occlusion at night. *Topical retinoids* such as tretinoin (0.01% gel and 0.1% cream) may also be tried; treatment is, however, often limited by skin irritation. *Potent topical corticosteroids*, such as clobetasol propionate 0.05%, with or without keratolytics, are occasionally of value in the management of inflammatory PPK. *5-Fluorouracil* 5% has produced dramatic results in spiny keratoderma, but its use in other keratodermas has not been evaluated.

The efficacy of the *oral retinoids* in keratoderma is well established. Good responses have been seen in mal de Meleda, Papillon–Lefèvre syndrome, and erythrokeratoderma variabilis. In some types of PPKs, particularly epidermolytic forms, hyperesthesia may limit the usefulness or practicality of treatment with retinoids. The potential risk of bone toxicity should also be assessed in patients on long-term therapy, although the risks are small. Periodic radiologic bone monitoring and, when possible, prescription of pulsed (intermittent) therapy are recommended. The optimal dosage of oral acitretin is 25 to 35 mg daily in adults or 0.6 mg/kg daily in children, which may be adjusted after 4 weeks of therapy. Oral isotretinoin 0.5 mg/kg is a less effective option. Oral alitretinoin 30 mg/day is a further option.

Psoralen plus UVA (PUVA) therapy or *re-PUVA* (a synergistic

combination of oral retinoids and PUVA) may be effective in PPK secondary to psoriasis or eczema. In oculocutaneous tyrosinemia (an autosomal recessive condition characterized by focal palmoplantar keratosis, corneal ulceration, and mental retardation), *dietary restriction of phenylalanine and tyrosine* has led to resolution of PPK. *Oral administration of 1 α ,25-dihydroxyvitamin D₃* and *topical calcipotriol* ointment has been reported to be effective. Regular podiatry, careful selection of footwear, and treatment of secondary fungal infections are integral parts of management of all PPK. Regular intermittent use of terbinafine cream and other topical antifungals can reduce skin maceration and improve comfort. *Surgical or laser dermabrasion* is an option for some patients, with potential amelioration of symptoms and improved penetration of topical agents.

For severe refractory PPK *excision and skin grafting* may be considered. Excision should remove hyperkeratotic skin, including dermis, epidermis, and subcutis, to prevent any risk of recurrence.

Specific Investigations

- Scrapings for mycology
- Thyroid function tests

An epidemiologic investigation of dermatologic fungus infections in the northernmost county of Sweden (Norrbotten) 1977–81

Gamborg Nielson P. *Mykosen* 1984; 27: 203–10.

In a 5-year survey of dermatophyte infections in Norrbotten, Sweden, the frequency of dermatophytosis among patients with hereditary PPK was shown to be 35%, corresponding to a prevalence of 36.7%. The predominant feature of dermatophytosis in patients with hereditary PPK was scaling and fissuring. Treatment improved the clinical signs after 2 to 3 months.

Hereditary palmoplantar keratoderma and dermatophytosis in the northernmost county of Sweden (Norrbotten)

Gamborg Nielson P. *Acta Derm Venereol Suppl* (Stockh) 1994; 188: 1–60.

In relatives of the original case, dermatophytosis was found in 65% of men, 22% of women, and 21% of children, resulting in a total

frequency of 36.2%. Statistically, it was proved that *Trichophyton mentagrophytes* occurred more often in patients with hereditary PPK. Vesicular eruptions along the hyperkeratotic border occurred significantly more often in patients with dermatophytosis and were considered pathognomonic of secondary dermatophytosis.

Palmoplantar keratoderma in association with myxoedema

Hodak E, David M, Feuerman EJ. Acta Derm Venereol 1986; 66: 354–5.

A patient with myxedema and intractable PPK showed improvement after treatment with thyroid replacement therapy. The possibility of a causal relationship between hypothyroidism and PPK was questioned.

Severe palmar keratoderma with myxoedema

Tan OT, Sarkany I. Clin Exp Derm 1977; 2: 287–8.

A patient with myxedema and PPK showed rapid improvement in PPK after thyroxine treatment.

First-Line Therapies

• Topical keratolytics	B
• Topical retinoids	B

Alleviation of the plantar discomfort caused by pachyonychia congenita with topical applications of aluminum chloride and salicylic acid ointments

Takayama M, Okuyama R, Sasaki Y, Ohura T, Tagami H, Aiba S. Dermatology 2005; 211: 302.

Aluminum chloride solution 10% once daily was used to reduce plantar sweating, which may exacerbate blistering and hyperkeratosis in this condition.

Vitamin A acid in the treatment of palmoplantar keratoderma

Gunther SH. Arch Dermatol 1972; 106: 854–7.

Nine patients with PPK were treated with once-daily retinoic acid 0.1% in petroleum jelly, and all improved within 4 months. Permanent remission ensued in two patients. Recurrence was observed in the majority of cases 8 weeks after the withdrawal of treatment. This was avoided by the topical application of vitamin A acid once or twice weekly.

Topical treatment of keratosis palmaris et plantaris with tretinoin

Touraine R, Revuz J. Acta Derm Venereol Suppl (Stockh) 1975; 74: 152–3.

Six patients were treated for 2 months with either tretinoin 0.1% lotion or 0.05% cream once daily. Improvement was seen in most patients. Better results were achieved with the use of occlusive dressings, mechanical paring before topical application, and when a higher concentration of topical tretinoin was used (0.3%).

Second-Line Therapy

• Systemic retinoids

A

The treatment of keratosis palmaris et plantaris with isotretinoin. A multicenter study

Bergfeld WF, Derbes VJ, Elias PM, Frost P, Greer KE, Shupack JL. J Am Acad Dermatol 1982; 6: 727–31.

Five of six patients with PPK were safely and effectively treated with isotretinoin, with dramatic clearing of the keratoderma within the first 4 weeks of therapy. The mean dose was 1.95 mg/kg daily, and mean duration of therapy was 113 days.

Acitretin in the treatment of severe disorders of keratinisation. Results of an open study

Blanchet-Bardon C, Nazzaro VV, Rognin C, Geiger JM, Puissant A. J Am Acad Dermatol 1991; 24: 982–6.

An open noncomparative study to evaluate the clinical response to acitretin in patients with nonpsoriatic disorders of keratinization and to establish the optimal dosage for efficacy and tolerance. Thirty-three patients with ichthyoses, PPK, or Darier disease were treated for 4 months. Most showed a marked improvement. The optimal acitretin dosage providing the best efficacy with minimal side effects varied from patient to patient. The mean daily dose ($\pm$ SD) was 27 ± 11 mg in adults and 0.7 ± 0.2 mg/kg in children.

A controlled study of comparative efficacy of oral retinoids and topical betamethasone/salicylic acid for chronic hyperkeratotic palmoplantar dermatitis

Capella GL, Fracchiolla C, Frigerio E, Altomare G. *J Dermatolog Treat* 2004; 15: 88–93.

A single-blind, matched-sample investigation was carried out in 42 patients with chronic hyperkeratotic palmoplantar dermatitis, who were administered acitretin 25 to 50 mg daily for 1 month controlled versus a conventional topical treatment (betamethasone/salicylic acid ointment). Acitretin was significantly better than the conventional treatment after 30 days (two-sided, $p < 0.0001$). The authors suggested that acitretin should be considered a first-choice treatment.

Acitretin in the treatment of mal de Meleda

Van de Kerkhof PC, Dooren-Greebe RJ, Steijlen PM. *Br J Dermatol* 1992; 127: 191–2.

Two patients with mal de Meleda treated with acitretin experienced a marked reduction of PPK. The optimal dosage was found to be 10 to 30 mg daily. Higher dosages resulted in hyperesthesia. Discontinuation of acitretin resulted in relapse within days.

Alitretinoin: a new treatment option for hereditary punctate palmoplantar keratoderma

Raone B, Raboni R, Patrizi P. *J Am Acad Dermatol* 2014; 71: e48–9.

A single patient case report demonstrating improvement of punctate keratoderma with alitretinoin 30 mg daily for 8 months.

Third-Line Therapies

• Reconstructive surgery with total excision of hyperkeratotic skin followed by grafting	C
• Topical calcipotriol	E
• Oral vitamin D ₃ analogs	E
• Topical corticosteroids with or without keratolytics	E
• PUVA or re-PUVA	D
• Dermabrasion	E
• CO ₂ laser	B
• 5-Fluorouracil	E
• Tyrosine-restricted diet in oculocutaneous keratoderma	E

Plastic surgery in the management of palmoplantar keratoderma (palmoplantar neoplasty)

Farina R. *Aesthet Plast Surg* 1987; 11: 249–53.

Five cases of PPK were treated successfully by grafting skin taken from the calves and thighs.

Palmoplantar keratoderma and skin grafting: postsurgical long-term follow-up of two cases with Olmsted syndrome

Bédard MS, Powell J, Laberge L, Allard-Dansereau C, Bortoluzzi P, Marcoux D. *Pediatr Dermatol* 2008; 25: 223–9.

A 6- and 10-year follow-up of successful surgical correction of mutilating keratoderma.

Surgical correction of pseudoainhum in Vohwinkel syndrome

Pisoh T, Bhatia A, Oberlin C. *J Hand Surg [Br]* 1995; 20: 338–41.

Successful surgical correction of constricting rings in a patient with Vohwinkel syndrome.

Surgical correction of hyperkeratosis in the Papillon–Lefèvre syndrome

Peled IJ, Weinrauch L, Cohen HA, Wexler MK. *J Dermatol Surg Oncol* 1981; 7: 142–3.

A patient with Papillon–Lefèvre syndrome underwent successful surgical correction of hyperkeratosis of the palms.

Topical calcipotriol in the treatment of epidermolytic palmoplantar keratoderma of Verner

Lucker GP, Van de Kerkhof PC, Steijlen PM. *Br J Dermatol* 1994; 130:

543–5.

A patient with hereditary epidermolytic PPK of Vorner was successfully treated with topical calcipotriol.

Efficacy, tolerability, and safety of calcipotriol ointment in disorders of keratinisation. Results of a randomized, double blind vehicle-controlled, right/left comparative study

Kragballe K, Steijlen PM, Ibsen HH, van de Kerkhof PC, Esmann J, Sorensen LH, et al. Arch Dermatol 1995; 131: 556–60.

Twenty patients with PPK showed no therapeutic benefit with topical calcipotriol.

Improvement of palmoplantar keratoderma of nonhereditary type (eczema tyloticum) after oral administration of 1 alpha 25-dihydroxyvitamin D3

Katayama H, Yamane Y. Arch Dermatol 1989; 125: 1713.

A patient with acquired PPK was successfully treated with oral 1 α ,25-dihydroxyvitamin D, 0.5 μ g daily for 3 months, with no side effects.

Oral psoralen photochemotherapy (PUVA) of hyperkeratotic dermatitis of the palms

Mobacken H, Rosen K, Swanbeck G. Br J Dermatol 1983; 109: 205–8.

PUVA was found to be effective in five patients with chronic hyperkeratotic dermatitis of the palms.

Dermabrasion of the hyperkeratotic foot

Daoud MS, Randle HW, Yarborough JM. Dermatol Surg 1995; 21: 243–4.

A patient with acquired PPK treated with dermabrasion and then 2% crude coal tar and 5% salicylic acid in petrolatum showed no evidence of recurrence after 6 months. The indications for dermabrasion include dry, fissured hyperkeratotic heels; psoriatic keratoderma before PUVA therapy; punctate keratoderma; and generalized keratoderma.

Methods and effectiveness of surgical treatment of limited hyperkeratosis with CO₂ laser

Babaev OG, Bashilov VP, Zakharov AK. Khirurgiia (Mosk) 1993; 4: 74–9.

Five hundred two patients with limited hyperkeratosis were treated, with a favorable clinical effect. Recurrences were noted in only 4% of cases

Dietary management of oculocutaneous tyrosinemia in an 11-year-old child

Ney D, Bay C, Scheider JA, Kelts D, Nyhan WL. Am J Dis Child 1983; 137: 995–1000.

An 11-year-old girl with oculocutaneous tyrosinemia with plantar keratosis and keratitis demonstrated resolution of her keratitis and improvement of her plantar keratosis with dietary restriction of phenylalanine and tyrosine to less than 100 mg/kg.

Palmoplantar pustulosis

Sonja Molin, and Thomas Ruzicka

Palmoplantar pustulosis (PPP) is a skin disease characterized by chronic and relapsing pustular eruptions of palms and soles. Because its clinical and genetic characteristics differ from psoriasis vulgaris, PPP probably must be considered a separate entity.

Management Strategy

PPP is a common disease that is often refractory to treatment and shows a high recurrence rate. Unlike psoriasis, there are no reported associations with candidate genes within the PSORS1 locus, interleukin-36 receptor antagonist mutations, or tumor necrosis factor (TNF)- α promoter polymorphisms. Female predominance and high prevalence in smokers are characteristic. *Cessation of smoking* is essential for the treatment course of PPP. Consideration of comorbidities such as streptococcal or *Helicobacter pylori* infection, diabetes mellitus, thyroid disease, celiac disease, or osteoarthropathy is necessary. *Tonsillectomy* can be helpful if a streptococcal focus is found. A *gluten-free diet* is recommended if gluten intolerance is proved. At the beginning of therapy and in patients with milder symptoms of PPP, potent *topical corticosteroids* are the treatment of choice and are even more effective when used *under occlusion*. *Psoralen and ultraviolet A light (PUVA)* therapy is also effective. In more severe or recalcitrant courses of disease, systemic medication should be considered. The retinoid *acitretin* (starting dose 0.3–0.5 mg/kg body weight) is of proven value, but its practical use in women is limited due to teratogenicity. There is evidence that the combination of PUVA with systemic retinoids is superior to the individual treatments. Low-dose *ciclosporin* (1–4 mg/kg daily) and *methotrexate* (10–25 mg once weekly) can cause improvement of PPP but requires careful clinical and laboratory monitoring. *Fumaric acid esters* have also been reported to be effective.

A multitude of other therapeutic proposals for the treatment of PPP decorate the literature. A new approach might be the vitamin D analog *maxacalcitol* for topical treatment. First studies show benefit compared with placebo.

Reports on *TNF- α antagonist* therapy in PPP show conflicting results, with many reports highlighting even induction or aggravation of the disease. Non-TNF- α -inhibiting biologic agents such as *ustekinumab* or *secukinumab*, as well as the new oral phosphodiesterase-4 inhibitor *apremilast*, might be promising new therapeutic options, especially in recalcitrant cases. Controlled clinical trials are needed to substantiate the evidence.

Specific Investigations

- Screen for infection with streptococci or *H. pylori*
- Gluten intolerance
- Thyroid disease
- Diabetes mellitus
- Osteoarthropathy
- Exclude SAPHO (synovitis, acne, pustulosis, hyperostosis, and osteitis)

Management of palmoplantar pustulosis: do we need to change?

Mrowietz U, van de Kerkhof PC. Br J Dermatol 2011; 164: 942–6.

Overview on PPP, also discussing current data on tonsillectomy and a probable “tonsil-palmoplantar-skin axis.”

Palmoplantar pustulosis associated with gastric *Helicobacter pylori* infection

Sáez-Rodríguez M, Noda-Cabrera A, García-Bustínduy M, Guimerá-Martín-Neda F, Dorta-Alom S, Escoda-García M, et al. Clin Exp Dermatol 2002; 27: 720.

Clearing of PPP in a patient with gastric *H. pylori* infection after eradication treatment with amoxicillin and clarithromycin in combination with omeprazole. No relapse of PPP during a 4-year follow-up.

Thyroid disease in pustulosis palmoplaris

Agner T, Sindrup JH, Høier-Madsen M, Hegedüs L. Br J Dermatol 1989; 121: 487–91.

In 53% of 32 patients with PPP thyroid disease was detected compared with 16% in the control group.

Osteoarticular manifestations of pustulosis palmaris et plantaris and of psoriasis: two distinct entities

Mejjad O, Daragon A, Louvel JP, Da Silva LF, Thomine E, Lauret P, et al. Ann Rheum Dis 1996; 55: 177–80.

Comparison of 23 patients with PPP and 23 patients with psoriatic arthritis (PsoA). Clinical findings showed involvement of the anterior chest wall (e.g., sternoclavicular joints) in 19 out of 23 patients with PPP compared with 10 out of 23 with PsoA. Radiologic signs of arthropathy were demonstrated in 11 PPP patients and four PsoA patients.

SAPHO syndrome: a long-term follow-up study of 120 cases

Hayem G, Bouchaud-Chabot A, Benali K, Roux S, Palazzo E, Silbermann-Hoffman O, et al. Semin Arthritis Rheum 1999; 29: 159–71.

Significant association of PPP with axial osteitis in 120 reported cases with SAPHO syndrome.

Women with palmoplantar pustulosis have disturbed calcium homeostasis and a high prevalence of diabetes mellitus and psychiatric disorders: a case-control study

Hagforsen E, Michaëlsson K, Lundgren E, Olofsson H, Petersson A, Lagumdzija A, et al. Acta Derm Venereol 2005; 85: 225–32.

Disturbed calcium homeostasis was found frequently in 60 PPP patients compared with control group. Association with diabetes mellitus, psychiatric disorders, and gluten intolerance was also reported.

Palmoplantar pustulosis and gluten sensitivity: a study of serum antibodies against gliadin and tissue transglutaminase, the duodenal mucosa and effects of gluten-free diet

Michaëlsson G, Kristjánsson G, Pihl Lundin I, Hagforsen E. Br J Dermatol 2007; 156: 659–66.

Laboratory investigation of 123 patients with PPP showed IgA antibodies against gliadin in 18% and antibodies against tissue transglutaminase in 10% of cases. Celiac disease was found in 6% of patients. Gluten-free diet resulted in (nearly) total clearance of skin symptoms and decrease of antibody level.

First-Line Therapies

• Oral retinoids	A
• PUVA	B
• Topical corticosteroids	C

Interventions for chronic palmoplantar pustulosis

Marsland AM, Chalmers RJ, Hollis S, Leonardi-Bee J, Griffiths CE. Cochrane Database Syst Rev 2006; 1: CD001433.

An extensive review of literature concerning PPP treatment showed proven evidence of PUVA and systemic retinoids alone or in combination; effectiveness of topical corticosteroids under occlusion; and probable benefit of low-dose ciclosporin, tetracycline antibiotics, and Grenz ray therapy.

A detailed survey of evidence-based PPP treatment options, including the classical publications regarding PUVA and systemic retinoids.

A hydrocolloid occlusive dressing plus triamcinolone acetonide cream is superior to clobetasol cream in palmo-plantar pustulosis

Kragballe K, Larsen FG. Acta Derm Venereol 1991; 71: 540–2.

Complete clearance of PPP with use of medium-strength topical corticosteroid under hydrocolloid occlusion in 13 out of 19 patients in a left–right comparison with a highly potent topical corticosteroid alone (complete remission only in 3 out of 19 patients).

Second-Line Therapies

• Ciclosporin	A
• Methotrexate	B
• Fumaric acid esters	C
• Excimer light therapy (308 nm)	C

Double-blind placebo-controlled study of long-term low-dose ciclosporin in the treatment of palmoplantar pustulosis

Erkko P, Granlund H, Remitz A, Rosen K, Mobacken H, Lindelöf B, et al. Br J Dermatol 1998; 139: 997–1004.

Fifty-eight PPP patients treated with ciclosporin in a daily dose of 1 to 4 mg/kg body weight for 12 months. Low-dose treatment showed improvement in 13 of 27 patients compared with 6 of 31 in the placebo group. Benefit of long-term use only supposed.

Pustulosis palmaris et plantaris treated with methotrexate

Thomsen K. Acta Derm Venereol 1971; 51: 397–400.

Satisfactory response in 8 out of 25 patients receiving weekly oral doses of 25 mg methotrexate for 2 months.

Efficacy of fumaric acid ester monotherapy in psoriasis pustulosa palmoplantaris

Ständer H, Stadelmann A, Luger T, Traupe H. Br J Dermatol 2003; 149: 220–2.

Marked reduction of PPP Area and Severity Index (PPPASi) in 13 patients with PPP treated with fumaric acid esters for a period of 24 weeks.

Efficacy of excimer light therapy (308 nm) for palmoplantar pustulosis with the induction of circulating regulatory T cells

Furuhashi T, Torii K, Kato H, Nishida E, Saito C, Morita A. Exp Dermatol 2011; 20: 768–70.

Significant improvement of PPPASi score after 20 to 30 treatments with excimer light therapy in 17 patients.

Third-Line Therapies

• Liarozole	A
• Ustekinumab	B
• Apremilast	A
• Maxacalcitol	A

**Dermatologic adverse reactions during anti-TNF treatments:
focus on inflammatory bowel disease**

Mocci G, Marzo M, Papa A, Armuzzi A, Guidi L. J Crohns Colitis 2013; 7: 769–79.

Review about the potential skin side effects of anti-TNF blockade, including psoriasiform lesions and PPP.

Benefit of TNF- α antagonist use in PPP is conflicting, with therapeutic efficacy, PPP initiation, or aggravation occurring.

Efficacy of ustekinumab in refractory palmoplantar pustular psoriasis

Morales-Múnera C, Vilarrasa E, Puig L. Br J Dermatol 2013; 168: 820–4.

Five PPP patients treated with ustekinumab responded.

Investigator-initiated, open-label trial of ustekinumab for the treatment of moderate-to-severe palmoplantar psoriasis

Au SC, Goldminz AM, Kim N, Dumont N, Michelon M, Volf E, et al. J Dermatolog Treat 2013; 24: 179–87.

Apremilast, an oral phosphodiesterase-4 inhibitor, in the treatment of palmoplantar psoriasis: results of a pooled analysis

from phase II PSOR-005 and phase III Efficacy and Safety Trial Evaluating the Effects of Apremilast in Psoriasis (ESTEEM) clinical trials in patients with moderate to severe psoriasis

Bissonnette R, Pariser DM, Wasel NR, Goncalves J, Day RM, Chen R, et al. J Am Acad Dermatol 2016; 75: 99–105.

Compared with placebo, a significant improvement was achieved in patients with moderate to severe PPP during treatment with apremilast. However, the study did not evaluate the presence of pustules/palmoplantar pustular lesions separately.

Phase III clinical study of maxacalcitol ointment in patients with palmoplantar pustulosis: a randomized, double-blind, placebo-controlled trial

Umezawa Y, Nakagawa H, Tamaki K. J Dermatol 2016; 43: 288–93.

Significant improvement in PPP patients treated topically with the vitamin D analog 22-oxacalcitriol twice daily for 8 weeks compared with placebo.

Panniculitis

Carrie Ann R. Cusack, and Christine M. Shaver

Panniculitis is a term used to describe the different inflammatory diseases of the subcutaneous fat. The subcutaneous fat is derived embryologically from mesenchymal cells, which differentiate into adipocytes, or fat cells. A collection of adipocytes is termed a *microlobule*, and groups of microlobules make up the individual lobules in the subcutaneous fat layer of the skin. Lobules are separated from each other by fibrous septae, and within these septae

are the main arteries and veins that nourish fatty tissue. Knowledge of the basic subcutaneous architecture allows for classification of the different types of panniculitides, which relies on distinguishing whether inflammation is predominantly located in the lobules or in the fibrous septae. Based on this classification, we can better separate the individual disease processes.

The characteristic septal panniculitis is erythema nodosum, which is also the most common panniculitis. The majority of other panniculitides are predominantly lobular. However, some other rarer panniculitides have predominantly septal inflammation, such as subacute nodular migratory panniculitis, panniculitis of morphea/scleroderma, and α 1-antitrypsin deficiency panniculitis. Within the lobular panniculitides, a further division can be made based on the presence of vasculitis.

The main lobular panniculitis with vasculitis is erythema induratum, or more aptly termed, *nodular vasculitis*. Rarer vasculitic panniculitides occur in the setting of leprosy with erythema nodosum leprosum and Lucio phenomenon.

The remaining lobular panniculitides are not associated with vasculitis but can be associated with systemic disease. Subtypes include lupus panniculitis, pancreatic panniculitis, cytophagic histiocytic panniculitis, panniculitis of dermatomyositis, infectious panniculitis, sclerosing panniculitis/lipodermatosclerosis, oxalosis, and those with needle-shaped clefts (sclerema neonatorum and subcutaneous fat necrosis of the newborn).

Previously the term *Weber–Christian disease (WCD)* has been described, which encompassed lobular panniculitides without vasculitis that also displayed nonspecific systemic features. It was largely a diagnosis of exclusion that has since fallen out of favor, as most cases previously classified as WCD have been able to be reclassified into newer and more specific diseases. A report by White and Winkelmann reviewed 30 cases of WCD and found that in all cases, a more specific diagnosis could be found. Therefore this terminology will not be used in our classification schema.

Management Strategy

Many studies can be performed in evaluating panniculitides; however, none is more important than the skin biopsy. Therefore it is extremely important that the biopsy includes a substantial portion of

the subcutaneous fat. A punch biopsy alone is not enough. Although a double punch biopsy technique is better, the best way to get a sample of subcutaneous tissue is either through an excisional biopsy that extends through the subcutis or a narrow incisional biopsy that includes a significant amount of fatty tissue. If an infectious cause of the panniculitis is suspected, a small piece of this biopsy should be sent for Gram staining as well as culture for bacteria, mycobacteria, and fungi. If a mycobacterial infection is in consideration, the specimen should be grown at 24°, 30°, 37°, and 42°C.

Lupus panniculitis, also known as *lupus profundus*, makes up a small portion of cutaneous lupus erythematosus, comprising only 2% to 3%. In many instances, it is the first cutaneous sign of lupus erythematosus. It is associated mainly with discoid lupus erythematosus (DLE), occurring in more than one third of cases of DLE. Lesions of DLE often are present in the skin overlying the lesions of lupus profundus (Image 1). Lupus panniculitis occurs in approximately 10% to 15% of patients with systemic lupus erythematosus (SLE), which tends to have a chronic course with few systemic manifestations, usually arthralgias. The distribution of these lesions can be helpful in making the diagnosis, as they are typically located on the face, trunk, and proximal extremities, in contrast to erythema nodosum. Laboratory studies should include ANA, dsDNA, ssDNA, SSA, SSB, complement levels, CBC, and a chemistry panel. On biopsy, it shows a predominantly lobular inflammation of T lymphocytes and macrophages. A biopsy for direct immunofluorescence (DIF) should be performed to confirm the diagnosis in cases where the histopathology is not specific. In many cases, linear deposition of C3 and IgM is present along the dermoepidermal junction in the overlying skin. First-line therapy for lupus profundus consists of systemic *antimalarial agents* as well as sunscreen. The addition of a second antimalarial agent has proven helpful in patients who are resistant to one agent. In addition, *systemic corticosteroids* can be used first line; however, they are usually effective only in the early phases of disease.

Nodular vasculitis includes both tuberculous and nontuberculous causes. The tuberculous form is referred to as *erythema induratum* (of *Bazin*). Nontuberculous etiologies include other infectious agents, such as *Nocardia* or hepatitis C virus, and medications such as propylthiouracil. The nontuberculous form has sometimes been referred to as *erythema induratum* of *Whitfield*. Clinically, lesions

appear on the posterior legs of middle-aged women and present as painful, erythematous nodules. In making the diagnosis, mycobacterial culture as well as polymerase chain reaction (PCR) of mycobacterial DNA should be ordered. Purified protein derivative as well as a Quantiferon-TB Gold test can be helpful in making the diagnosis caused by tuberculosis. On biopsy, it is typically a lobular panniculitis with a mixed inflammation of lymphocytes and neutrophils. The key is identifying vasculitis, as the majority of cases show inflammation of either arteries or veins. Treatment includes *multidrug antituberculous* agents in cases caused by tuberculosis, and other antibiotics in cases of other infectious etiologies. Other effective therapies *include potassium iodide, colchicine, and corticosteroids*.

Pancreatic panniculitis can occur in many different pancreatic disorders that cause tissue necrosis. This includes acute or chronic pancreatitis, pancreatic carcinoma (most often the acinar cell type), pancreas divisum, and pancreatic pseudocysts. It occurs in about 2% to 3% of all cases of pancreatic diseases. The presence of panniculitis may precede the detection of pancreatic disease and warrants an investigation for potential etiologies. It may be a harbinger of metastasis in cases of pancreatic carcinoma. Lesions consist of subcutaneous nodules that usually occur on the legs (around the ankles and knees predominantly) but can occur in any location. The nodules may or may not be painful, but the majority of lesions ulcerate, discharging an oily brown substance. Histopathology shows fat necrosis, and formation of “ghost cells” is classic. Amylase and, more specifically, lipase are elevated in pancreatic panniculitis and should be ordered. A CBC should be ordered as well, as eosinophilia may be present in 60% of cases. Magnetic resonance imaging (MRI) can identify a pancreatic *malignancy*. *Treatment involves addressing the underlying pancreatic inflammation*. Octreotide has also been helpful.

Cytophagic histiocytic panniculitis is defined based on the presence of hemophagocytosis on histopathology. There are characteristic “bean-bag cells,” which are macrophages that engulf lymphocytes, neutrophils, and erythrocytes. The vast majority of cases are caused by a lymphoma. The main types are Epstein–Barr virus–associated extranodal NK/T-cell lymphoma and primary cutaneous gamma/delta T-cell lymphoma. Clinically, painful subcutaneous nodules are present. Patients may have a prolonged clinical course with fever, hepatosplenomegaly, and pancytopenia secondary to hemophagocytosis of the bone marrow. Many cases of cytophagic

histiocytic panniculitis are now being classified on a spectrum with subcutaneous panniculitis–like T-cell lymphoma (SPTCL) as the two diseases share many clinical and histopathologic characteristics. Treatment of cytophagic histiocytic panniculitis consists of *treating any underlying malignancy*, possibly with a bone marrow transplant. In cases where lymphoma has not been identified, cyclosporine has been effective.

α 1-Antitrypsin deficiency panniculitis occurs in patients with a severe deficiency of this enzyme, a protease inhibitor. Many different alleles of the gene encode this protein, with the most common being the M allele. The most common phenotype for the protease inhibitor (Pi) is PiMM. Patients with the S or Z allele may exhibit a mild deficiency in the enzyme. Patients with the phenotype PiZZ have the most severe enzyme deficiency, and it is typically these patients who manifest the panniculitis. Inflammation in the subcutaneous fat occurs because lipase, elastase, and other enzymes are not neutralized. These patients have painful, often purpuric nodules that ulcerate and drain. On pathology, there is usually focal necrosis of the fat lobules with a predominantly neutrophilic inflammation. An elastin stain may be helpful to show the reduced elastic tissue, and gene phenotyping can reveal an enzyme mutation. The most effective treatment is *enzyme replacement* through intravenous injections. Other treatments include *dapsone, colchicine, and liver transplantation*.

Panniculitis can also occur in infants. The two main types are sclerema neonatorum and subcutaneous fat necrosis of the newborn. They both are characterized histologically by needle-shaped clefts within lipocytes. In sclerema neonatorum, an extremely rare condition, the skin becomes hardened on the buttocks or thighs and then rapidly spreads in the first few days of life, causing immobility. Death typically occurs in a few days. Treatment for this condition is disappointing. It *involves supportive care, treating any underlying condition, and exchange transfusions*. The prognosis for subcutaneous fat necrosis of the newborn, on the other hand, is good. This disease involves full-term infants in contrast to premature newborns in sclerema neonatorum. Clinically, this condition consists of localized, indurated plaques involving the trunk that form during the first few weeks of life. Most lesions resolve spontaneously, and treatment is supportive. It may be complicated by hypercalcemia and therefore serial monitoring of calcium levels for at least 4 months after disease resolution is suggested, and treatment of resultant hypercalcemia

may be required.

Lipodermatosclerosis, or sclerosing panniculitis, is a condition that usually develops in patients with chronic venous insufficiency. It is classically located on the medial lower legs in middle-aged women. It has been described as looking like an “inverted champagne bottle.” Histologically there are ischemia and necrosis of the central fat lobule, leading to characteristic lipomembranous changes. Treatment involves *correcting the venous insufficiency* with compression stockings and leg elevation. *Stanozolol* has also been helpful.

Panniculitis can also occur in the setting of other connective tissue diseases such as dermatomyositis and morphea/scleroderma. In morphea, usually there is a septal panniculitis with a plasma lymphocytic cell infiltrate. Indurated plaques appear on the trunk and extremities. In dermatomyositis, the panniculitis is more lobular, and the inflammation is primarily lymphocytic. Clinically, there are tender, indurated plaques that may ulcerate and heal with atrophy. Treatment of both conditions involves treating the underlying connective tissue disease.

The physical forms of panniculitis, such as those resulting from cold exposure, foreign body, or factitious causes, usually resolve by removal of the offending trigger or surgical removal of the foreign body. This is similar to panniculitis caused by silicone or paraffin that has been used for cosmetic purposes. There are also forms of panniculitis associated with chronic renal failure, with the main ones being calciphylaxis and oxalosis. Calciphylaxis can cause large areas of necrosis. Treatment involves *parathyroidectomy, sodium thiosulfate, binding agents, or renal transplantation*. Oxalosis is a crystalline deposit panniculitis. Calcium oxalate crystals typically are deposited on the palmar fingers, among other locations. Treatment for this is *renal transplantation*.

Finally, panniculitis may also be drug induced. Of note, vemurafenib, used in the treatment of unresectable or metastatic melanoma harboring the BRAF-V600E mutation, has led to 30 cases of associated panniculitis in the literature. The observed lesions are usually multiple, located on the lower limbs, and often of the lobular type. Withdrawal of the drug can result in resolution.

Specific Investigations

- Skin biopsy for routine microscopy (most important)
- Skin biopsy for culture and sensitivity (routine, mycobacterial, fungal)
- Skin biopsy for PCR
- Skin biopsy for immunoperoxidase and gene rearrangement studies
- ANA and other rheumatologic serologic tests
- Serum α 1-antitrypsin levels
- Serum lipase and amylase
- Abdominal MRI
- Complete blood count with differential
- Chemistry panel

Lupus Panniculitis

First-Line Therapies

• Antimalarials	E
• Systemic corticosteroids	E

Connective tissue panniculitis: lupus panniculitis, dermatomyositis, morphea/scleroderma

Hansen CB, Callen JP. Dermatol Ther 2010; 23: 341–9.

A review article that touts oral antimalarials and sunscreen as first-line treatment for lupus profundus. Hydroxychloroquine is recommended at 200 mg twice a day with a maximum dose of 6.5 mg/kg/day. The onset of action is around 4 to 8 weeks but can take up to 6 months for optimal benefit. Chloroquine is also recommended at 250 to 500 mg/day but has a higher risk of ophthalmologic toxicity.

Systemic lupus erythematosus presenting as panniculitis (lupus profundus)

Diaz-Jouanen E, DeHoratius RJ, Alarcón-Segovia D, Messner RP. Ann

Intern Med 1975; 82: 376–9.

A case study in which five or six patients improved after adding hydroxychloroquine to their systemic corticosteroid regimen.

Connective tissue panniculitis

Winkelmann RK, Padilha-Goncalves A. Arch Dermatol 1980; 116: 291–4.

Case report of a patient obtaining remission with hydroxychloroquine 200 mg twice daily and systemic corticosteroids. However, she developed SLE. A second patient on hydroxychloroquine was cleared of the condition after failing to respond to nonsteroidal antiinflammatory drugs (NSAIDs), potassium iodide, and corticosteroids.

Lupus erythematosus panniculitis (profundus)

Maciejewski W, Bandmann HJ. Acta Derm Venereol 1979; 59: 109–12.

Case report of a patient diagnosed with lupus profundus by direct immunofluorescence and treated with chloroquine.

Lupus erythematosus presenting as panniculitis

Verbov JL, Borrie PR. Proc R Soc Med 1971; 64: 28–9.

A case report of the condition clearing in one patient with hydroxychloroquine 200 mg twice daily.

Second-Line Therapies

• Topical corticosteroids under occlusion	E
• Second antimalarial agent	E

Lupus erythematosus profundus treated with clobetasol propionate under a hydrocolloid dressing

Yell JA, Burge SM. Br J Dermatol 1993; 128: 103.

A single case of a cure with clobetasol under hydrocolloid dressing occlusion, changed weekly. The patient responded after 1 month.

Lupus panniculitis treated by a combination therapy of

hydroxychloroquine and quinacrine

Chung HS, Hann SK. J Dermatol 1997; 24: 569–72.

In this case report, a 24-year-old male presented with nontender, indurated plaques on the left facial and submandibular regions. Histopathologic and DIF studies confirmed the diagnosis of lupus profundus. The patient had marginal improvement with either hydroxychloroquine or systemic steroids alone. However, combination of hydroxychloroquine and quinacrine together cleared the lesions.

Third-Line Therapies

• Intravenous immunoglobulin (IVIG)	E
• Rituximab	E
• Gold	E
• Bismuth	E
• Thalidomide	E
• Cyclosporine	E
• Dapsone	E
• Mycophenolate mofetil	E

Intravenous immunoglobulin in lupus panniculitis

Santo JE, Gomes MF, Gomes MJ, Peixoto LC, Pereira S, Acabado A, et al. Clin Rev Allergy Immunol 2010; 38: 307–18.

The patient was a 51-year-old Caucasian female who initially developed nodular lesions on the abdomen and limbs. Pathology and DIF were consistent with lupus panniculitis. She was initially treated with hydroxychloroquine but developed transaminitis and had biopsy-proven hepatic inflammation. Systemic steroids and

azathioprine yielded no response as well. On thalidomide 300 mg, the patient developed neuropathy and diarrhea. She was then started on dapsone but again developed transaminitis. After 15 years of failing different therapies, she was started on IVIG once monthly for 6 months and saw complete regression of the subcutaneous nodules. The doses were spread out to every 3 months, and the patient remained in remission.

Rituximab for the treatment of lupus erythematosus panniculitis

Moreno-Suarez F, Pulpillo-Ruiz A. *Dermatol Ther* 2013; 26: 415–8.

Two patients presented with lupus profundus refractory to several therapies and demonstrated brisk improvement after infusion of rituximab at a dosage of 375 mg/m²/week. Painful lesions resolved after the first infusion, and no further lesions appeared.

A case of “refractory” lupus erythematosus profundus responsive to rituximab [case report]

McArdle A, Baker JF. *Clin Rheumatol* 2009; 28: 745–6.

The patient was a 22-year-old African American female who presented with painful nodules on the buttocks, consistent with a diagnosis of lupus panniculitis. The patient was started on prednisolone 1 mg/kg and hydroxychloroquine but continued to worsen. Mycophenolate mofetil resulted in significant nausea and vomiting. Rituximab, an anti-CD20 monoclonal antibody, was then considered. The dosage was 1000 mg administered 2 weeks apart. Over a 1-month period, the patient had complete resolution of all signs of lupus profundus.

Lupus erythematosus profundus

Arnold HL Jr. *Arch Dermatol* 1956; 73: 14–26.

One patient had a partial response to IV gold followed by bismuth sodium thioglycolate.

Facets of lupus erythematosus: panniculitis responding to thalidomide

Wienart S, Gadola S, Hunziker T. *J Deutschen Dermatologischen Gesellschaft* 2008; 6: 214–6.

Lupus erythematosus profundus with partial C4 deficiency responding to thalidomide

Burrows NP, Walport MJ, Hammond AH, Davey N, Jones RR. Br J Dermatol 1991; 125: 62–7.

A female patient with disfiguring lupus erythematosus profundus from the age of 13 years was found to have an isolated partial C4 deficiency. Marked improvement in her cutaneous lesions occurred with thalidomide.

The dynamism of cutaneous lupus erythematosus: mild discoid lupus erythematosus evolving into SLE and SCLE and treatment-resistant lupus panniculitis

Wozniacka A, Salamon M, Lesiak A, McCauliffe DP, Sysa-Jedrzejowska A. Clin Rheumatol 2007; 26: 1176–9.

A 47-year-old woman with biopsy-proven lupus panniculitis responded to cyclosporine at a dose of 4 mg/kg/day in addition to methylprednisolone. After 10 days, there was improvement. The steroids were tapered and stopped after 3 months, and cyclosporine was gradually tapered to 2 mg/kg/day. The patient had previously failed antimalarials, systemic steroids, azathioprine, cyclophosphamide, methotrexate, and pulse doses of methylprednisolone.

Lupus erythematosus profundus successfully treated with dapsone: review of the literature

Ujiie H, Shimizu T, Ito M, Arita K, Shimizu H. Arch Dermatol 2006; 142: 399–401.

A 56-year-old woman with ulcerated, biopsy-proven lupus profundus responded to dapsone at a dose of 75 mg/day after 6 weeks.

Nodular Vasculitis

First-Line Therapies

• Potassium iodide	D
• Treat underlying tuberculosis	B

Potassium iodide in the treatment of erythema nodosum and nodular vasculitis

Horio T, Imamura S, Danno K, Ofuji S. Arch Dermatol 1981; 117: 29–31.

A case study in which 11 of 51 patients had nodular vasculitis. Seven of the 11 patients responded within 2 weeks to potassium iodide 300 mg three times daily.

Treatment of erythema nodosum and nodular vasculitis with potassium iodide

Schulz EJ, Whiting DA. Br J Dermatol 1976; 94: 75–8.

Sixteen of 17 patients responded to potassium iodide, usually with relief of symptoms within 2 days. The average duration of therapy was 3 weeks, and daily doses ranged from 360 to 900 mg.

Successful treatment of erythema induratum of Bazin following rapid detection of mycobacterial DNA by polymerase chain reaction

Degitz K, Messer G, Schirren H, Classen V, Meurer M. Arch Dermatol 1993; 129: 1619–20.

A single case of erythema induratum successfully treated with isoniazid, rifampin, and ethambutol.

Erythema induratum of Bazin

Cho KH, Lee DY, Kim CW. Int J Dermatol 1996; 35: 802–8.

A retrospective study of 32 patients with erythema induratum of Bazin. All improved with triple antituberculous therapy, but four relapsed and subsequently cleared.

Diagnosis and treatment of erythema induratum (of Bazin)

Feiwei M, Munro DD. Br Med J 1965; 1: 1109–11.

Twelve patients were diagnosed with erythema induratum secondary to tuberculosis, and all responded well to two- to three-drug therapy: streptomycin, p-aminosalicylic acid 12.5 mg daily, and isoniazid 200 to 260 mg daily for 9 months.

Second-Line Therapies

• NSAIDs	E
• Antimalarials	E
• Colchicine	E

Neutrophilic vascular reactions

Jorizzo JL, Solomon AR, Zanolli MD, Leshin B. J Am Acad Dermatol 1988; 19: 983–1005.

A review article in which nodular vasculitis is one of the causes of necrotizing vasculitis. NSAIDs may benefit serum sickness–like features but do not help cutaneous lesions.

Chloroquine-induced remission of nodular panniculitis present for 15 years

Shelley WB. J Am Acad Dermatol 1981; 5: 168–70.

One patient with nodular panniculitis responded within 1 month to chloroquine 250 mg/day after failing to respond to corticosteroids, NSAIDs, and tetracycline.

Cutaneous necrotizing vasculitis

Lotti T, Comacchi C, Ghersetich I. Int J Dermatol 1996; 35: 457–74.

By inhibiting neutrophil chemotaxis, oral colchicine in doses of 0.6 mg twice daily may be helpful in chronic forms of the disease.

Third-Line Therapies

• Gold	E
• Mycophenolate mofetil	E

Nodular vasculitis (erythema induratum): treatment with auranofin

Shaffer N, Kerdel FA. J Am Acad Dermatol 1991; 25: 426–9.

One patient with nodular vasculitis responded to oral gold 3 mg twice daily and improved after 3 weeks. She had previously failed to respond to prednisone, colchicine, D-penicillamine, sulindac, and bumetanide for suspected erythema nodosum.

Case reports: nodular vasculitis responsive to mycophenolate mofetil

Taverna JA, Radfar A, Pentland A, Poggioli G, Demierre MF. J Drugs Dermatol 2006; 5: 992–3.

A 70-year-old woman was treated with 1 g of mycophenolate mofetil twice daily. She slowly responded over a 1-year period.

Pancreatic Panniculitis

First-Line Therapies

• Treat underlying pancreatic condition	E
• Resection of metastases of pancreatic cancer	E

Resolution of panniculitis after placement of pancreatic duct stent in chronic pancreatitis

Lambiase P. Am J Gastroenterol 1996; 91: 1835–7.

One patient with pancreatitis secondary to alcohol presented with chest pain and tender skin nodules on the shins. After a skin biopsy

showed panniculitis, he was diagnosed with pancreatitis without abdominal pain but a high amylase. A stent was placed to correct a stricture in the pancreatic duct, leading to resolution of the symptoms and the skin lesions within 1 month.

Panniculitis caused by acinous pancreatic carcinoma

Heykarts B, Anseeuw M, Degreef H. *Dermatology* 1999; 198: 182–3.

One patient with skin nodules was found to have acinar pancreatic carcinoma upon surgical resection. She was initially unresponsive to high-dose corticosteroids and methotrexate, but the skin lesions resolved slowly after the resection. Subsequently, metastases were found in the right liver, and the patient failed to respond to fluorouracil.

Resolution of pancreatic panniculitis following metastasectomy

Banfill KE, Oliphant TJ, Prasad KR. *Clin Exp Dermatol* 2012; 37: 440–1.

A 69-year-old man presented with a 6-month history of painful skin lesions. Three months after developing the skin lesions, a computed tomography (CT) scan revealed a large necrotic mass in the liver consistent with a metastasis. The patient underwent resection of a solitary liver metastasis, which resulted in complete resolution of his panniculitis.

Second-Line Therapy

• Octreotide

E

Liquefying panniculitis associated with acinous carcinoma of the pancreas responding to octreotide

Hudson-Peacock MJ, Regnard CF, Farr PM. *J R Soc Med* 1994; 87: 361–2.

One patient presented with increasing numbers of painful leg nodules secondary to poorly differentiated adenocarcinoma. She

failed to respond to prednisolone, but octreotide 50 µg twice daily subcutaneously halted progression of the skin nodules. However, despite therapy, the patient died 3 weeks later.

Cytophagic Histiocytic Panniculitis

First-Line Therapies

• Treat underlying T-cell lymphoma (chemotherapy)	E
• Prednisone	E
• Cyclosporine	E

Cytophagic histiocytic panniculitis and subcutaneous panniculitis-like T-cell lymphoma: report of 7 cases

Marzano AV, Berti E, Paulli M, Caputo R. Arch Dermatol 2000; 136: 889–96.

A report of seven cases of cytophagic histiocytic panniculitis (CHP). Five patients had subcutaneous T-cell lymphoma and died after failing to respond to various chemotherapeutic agents. One patient has done well with prednisone for 13 months, and the other living patient has done well with systemic corticosteroids, cyclophosphamide, and dapsone for 36 years.

Successful treatment of cytophagic histiocytic panniculitis with modified CHOP-E: cyclophosphamide, adriamycin, vincristine, prednisone, and etoposide

Matsue K, Itoh M, Tsukuda K, Miyazaki K, Kokubo T. Am J Clin Oncol 1994; 17: 470–4.

One patient with CHP received eight courses of modified CHOP-E every 3 weeks and obtained a remission that has lasted 2 years.

Cytophagic histiocytic panniculitis. Case report with resolution after treatment

Alegre VA, Fortea JM, Camps C, Aliaga A. J Am Acad Dermatol 1989; 20: 875–8.

One patient with CHP for 2 months was treated with cyclophosphamide, vincristine, doxorubicin, and prednisone for nine cycles and achieved a cure. The authors recommend early, aggressive treatment.

Cytophagic histiocytic panniculitis – a syndrome associated with benign and malignant panniculitis: case comparison and review of the literature

Craig AJ, Cuaing H, Thomas G, Lamerson C, Smith R. J Am Acad Dermatol 1998; 39: 721–36.

Case report of two patients with CHP. One patient responded to prednisone plus cyclosporine 15 mg/kg/day. The other patient died during treatment with chemotherapy for T-cell lymphoma.

Subcutaneous panniculitic T-cell lymphoma in children: response to combination therapy with cyclosporine and chemotherapy

Shani-Adir A, Lucky AW, Prendiville J, Murphy S, Passo M, Huang FS, et al. J Am Acad Dermatol 2004; 50: S18–22.

A case report of two adolescents with CHP. Both responded symptomatically to cyclosporine, and complete remission was obtained in one with chemotherapy.

Successful treatment of severe cytophagic histiocytic panniculitis with cyclosporine A

Ostrov BE, Athreys BH, Eichenfield AH, Goldsmith DP. Semin Arthritis Rheum 1996; 25: 404–13.

A 16-year-old patient with CHP who was on prednisone flared and cyclosporine was added. At a dose of 4 mg/kg/day, remission occurred.

Second-Line Therapies

• Tacrolimus	E
• Bone marrow transplantation	E
• Potassium iodide	E
• Dapsone	E
• Cyclophosphamide	E
• Irradiation	E
• Anakinra	E

Successful treatment of cyclosporine-A-resistant cytophagic histiocytic panniculitis with tacrolimus

Miyabe Y, Murata Y, Baba Y, Ito E, Nagasaka K. Mod Rheumatol 2011; 21: 553–6.

A 34-year-old female with CHP initially failed treatment with high-dose prednisolone with cyclosporine. After changing cyclosporine to tacrolimus, the CHP responded.

Effective high-dose chemotherapy followed by autologous peripheral blood stem cell transplantation in a patient with the aggressive form of cytophagic histiocytic panniculitis

Koizumi K, Sawada K, Nishio M, Katagiri E, Fukae J, Fukada Y, et al. Bone Marrow Transplant 1997; 20: 171–3.

One patient with CHP was treated with CHOP-E and GM-CSF and achieved remission. He was subsequently treated with bone marrow transplant and remained disease free for 1 year.

Cytophagic histiocytic panniculitis is not always fatal

White JW Jr, Winkelmann RK. J Cutan Pathol 1989; 16: 137–44.

One patient with CHP was treated with potassium iodide and

achieved remission for 15 years.

Successful treatment of a patient with subcutaneous panniculitis-like T-cell lymphoma with high-dose chemotherapy and total body irradiation

Mukai HY, Okoshi Y, Shimizu S, Katsura Y, Takei N, Hasegawa Y, et al. Eur J Haematol 2003; 70: 413–16.

One patient with CHP and T-cell lymphoma achieved remission after three courses of CHOP followed by total body irradiation and autologous stem cell transplant.

Interleukin 1 receptor antagonist to treat cytophagic histiocytic panniculitis with secondary hemophagocytic lymphohistiocytosis

Behrens EM, Kreiger PA, Cherian S, Cron RQ. J Rheumatol 2006; 33: 2081–4.

A 14-year-old girl with CHP who failed cyclosporine and etoposide responded to methylprednisolone and anakinra.

α_1 -Antitrypsin Deficiency Panniculitis

First-Line Therapies

• Doxycycline	E
• Dapsone	D
• α_1 -Antitrypsin concentrate	E
• Liver transplant	E

Use of anticollagenase properties of doxycycline in treatment of alpha 1-antitrypsin deficiency panniculitis

Humbert P, Faivre B, Gibey R, Agache P. *Acta Derm Venereol* 1991; 71: 189–94.

Three patients with recurrent α_1 -antitrypsin (A1AT) panniculitis were treated with doxycycline 200 mg daily for 3 months. All cleared within 8 weeks.

Clinical and pathologic correlations in 96 patients with panniculitis including 15 patients with deficient levels of alpha 1-antitrypsin

Smith KC, Su Pittelkow MR, Winkelmann RK. *J Am Acad Dermatol* 1989; 21: 1192–6.

Fifteen patients had A1AT panniculitis. Out of six treated with dapsone, five responded.

Unusual acute sequelae of alpha 1-antitrypsin deficiency: a myriad of symptoms with one common cure

Franciosi AN, McCarthy C, Carroll TP, McElvaney NG. *Chest* 2015; 148: 136–8.

A single case of biopsy-proven A1AT panniculitis that cleared after one dose of IV A1AT at a dose of 120 mg/kg.

Alpha 1-antitrypsin deficiency-associated panniculitis: resolution with intravenous alpha 1-antitrypsin administration and liver transplantation

O’Riordan K, Blei A, Rao MS, Abecassis M. *Transplantation* 1997; 63: 480–2.

Two patients with homozygous deficiency had panniculitis. One received cure with liver transplant, whereas the other received intravenous A1AT and was clear while on this medicine.

Treatment of alpha-1-antitrypsin deficiency, massive edema, and panniculitis with alpha-1 protease inhibitor

Furey NL, Golden RS, Potts SR. *Ann Intern Med* 1996; 125: 699.

A patient with red thigh nodules was found to have A1AT-deficiency panniculitis. The patient failed to respond to doxycycline and received α_1 -protease concentrate and improved within 24 hours.

Second-Line Therapies

• Potassium iodide	E
• Plasmapheresis	E
• Cyclophosphamide	E
• Colchicine	E
• Prednisone	E

**Atlantic Provinces Dermatology Association Society Meeting,
May 3, 1986**

Miller RAW, cited by Ross JB. J Can Dermatol Assoc 1986; 13–7.

One patient with A1AT-deficiency panniculitis failed to respond to prednisone and azathioprine but responded after switching to dapsone, potassium iodide, and plasmapheresis two to three times per week.

**Cyclophosphamide therapy for Weber–Christian disease
associated with alpha 1-antitrypsin deficiency**

Strunk RW, Scheld WM. South Med J 1986; 79: 1425–7.

One patient with A1AT-deficiency panniculitis failed to respond to prednisone and heparin. Cyclophosphamide was added with good response.

Necrotic panniculitis with alpha-1 antitrypsin deficiency

Viraben R, Massip P, Dicostanzo B, Mathieu C. J Am Acad Dermatol 1986; 14: 684–7.

A patient with A1AT-deficiency panniculitis failed to respond to prednisolone, lincomycin, colchicine, and cyclophosphamide. Rapid improvement occurred after plasma exchange transfusions once daily for 8 weeks.

Familial occurrence of alpha 1-antitrypsin deficiency and Weber-Christian disease

Breit SN, Clark P, Robinson JP, Luckhurst E, Dawkins RL, Penny R. Arch Dermatol 1983; 119: 198–202.

A report of two cases of A1AT-deficiency panniculitis. One patient responded once cyclophosphamide was added to the initial treatment with dexamethasone. The other patient received colchicine and dicloxacillin and the panniculitis resolved.

Severe panniculitis caused by homozygous ZZ alpha 1-antitrypsin deficiency treated successfully with human purified enzyme (Prolastin)

Chowdhury MM, Williams EJ, Morris JS, Ferguson BJ, McGregor AD, Hedges AR, et al. Br J Dermatol 2002; 147: 1258–61.

Life-threatening panniculitis and skin necrosis was cleared with Prolastin and prednisolone. She was put on a dose of 100 mg/kg every 6 days.

Papular urticaria

Hee J. Kim, and Jacob O. Levitt

Papular urticaria is a common disease characterized by chronic or recurrent eruptions of 3- to 10-mm pruritic papules, wheals, vesicles, or bullae with central pallor caused by hypersensitivity to the bites of arthropods. Not all individuals who are bitten by an offending

arthropod develop a reaction. However, when a bite results in a pruritic papular eruption more persistent than typical urticaria, such dermatologic manifestation is described as papular urticaria. These papules characteristically present as clusters on the extensor surfaces of arms and legs; however, location is largely dependent on the offending arthropod. Eruptions are less often found on the face, neck, trunk, buttocks, or thighs and typically spare the genital, perianal, and axillary regions. Individual lesions may last for 2 to 10 days and rarely longer. Intense pruritus associated with papular urticaria often leads to excoriations, lichenification, and secondary infection. Cases have been reported in infants as young as 2 weeks old but are generally seen in children 2 to 7 years old and in adult males. There is a predilection for the spring and summer months when insect populations peak.

Management Strategy

The exact cause of papular urticaria is often unidentified; hence, it is a diagnosis of exclusion. Initial evaluation should include complete blood count with differential, serum IgE, scratch test for dermographism, environmental evaluation, and even skin biopsy if considering systemic treatment.

Given the lack of evidence-based treatments for papular urticaria, we have suggested a therapeutic ladder that addresses (1) a presumed arthropod assault, (2) the pathophysiology of the allergic and inflammatory response, and (3) the severity of the inflammation at presentation.

The most effective treatment for papular urticaria is the *identification and removal of the offending arthropod*. This may require intense investigation by both physician and patient. *Empiric therapy for scabies* should be given because benefits outweigh the risks. This can be achieved with application of permethrin cream 5% or malathion lotion 0.5% once and re-application 3 to 7 days later. In the case of suspected bed bugs and fleas, *fumigation of the home* is required using professional services. Fumigation of the home should also be considered in recurrent cases of papular urticaria. Clothes and bedding should be laundered before and after treatment; specifically, they should be placed in a dryer at 60°C for 10 minutes to dehydrate and kill scabies and bed bugs. In persistent cases, application of diethyl-m-toluamide (DEET) before bed may help. If there are pets in

the home, *aggressive flea control* and veterinary evaluation may be necessary. If the exposure is thought to be from the outdoors, prevention can be achieved through *protective clothing* and *insect repellents*.

While the cause of papular urticaria is being investigated and treated, symptomatic therapy should be implemented immediately for patient comfort. The goal of symptomatic therapy is to reduce and prevent inflammation. The degree of aggressiveness in therapy depends on the degree of inflammation at presentation. For milder cases, *topical steroids* should be prescribed, with choice of class depending on the severity of lesions. For individual refractory or severe lesion, *intralesional triamcinolone* is often helpful. If these are ineffective or if the inflammatory response is severe on initial presentation, proceed to systemic immunosuppression—for example, a 10-day *oral prednisone* taper starting at 1 mg/kg or 1 mg/kg of intramuscular triamcinolone. Systemic corticosteroids will often permanently blunt the inflammatory reaction, provided the antigenic stimulus has been removed. If papular urticaria becomes chronic in the context of two failed courses of systemic steroids and negative pest control investigations, other systemic immunosuppressants should be considered, such as *phototherapy*, *ciclosporin*, or *methotrexate*.

Pruritus control is often achieved with antihistamines. In milder cases, *nonsedating antihistamines* such as loratadine, desloratadine, fexofenadine, cetirizine, or levocetirizine can help alleviate symptoms. Doses above those given on the product labeling may be necessary. With more severe itching, *diphenhydramine* and *hydroxyzine* are favored. In chronic or recurrent cases, T-cell-mediated lesions, in contrast to the histamine-mediated lesions of early papular urticaria, may render antihistamines ineffective. In that case, topical agents, such as *camphor/menthol*, *calamine lotion*, *crotamiton*, *lidocaine*, and *pramoxine* can help.

Careful attention should be paid to any signs of infection secondary to scratching, and appropriate *topical or oral antibiotics* should be used.

Infrequently, cases of papular urticaria persist without the offending arthropod ultimately being identified. Although rare, hospitalizing the patient for a period of 3 to 7 days, while simultaneously treating for scabies on admission, results in resolution as reexposure to arthropod antigenic stimuli ceases in the hospital environment. In refractory cases, eruptions will continue until the patient is naturally hyposensitized over time. Hyposensitization can

take years to develop, and the concept can be especially confusing to those who have no pets in the home or for those where only one family member is affected.

Specific Investigations

- Environmental evaluation
- Complete blood count with differential
- Serum IgE
- Scratch test for dermatographism
- Skin biopsy (if systemic treatment is being given)

Bed bugs (*Cimex lectularius*) tend to live in wallpaper, mattress seams, couches, and headboards but can also be found in luggage, vehicles, and clothing. Importantly, they can live away from a host for up to 1 year after just one blood meal and can be spread via used furniture as well as travelers (clothing, baggage). They feed at night every 4 to 12 minutes and typically cause a painless bite of which the host is unaware. In vitro, bed bugs have been found to transmit hepatitis B, but there is no evidence for human transmission. Bed bugs are detected by human inspection, bed bug-sniffing dogs, and carbon dioxide-emitting monitoring systems.

Papular urticaria: a histopathologic study of 30 patients

Jordaan HF, Schneider JW. Am J Dermatopathol 1997; 19: 119–26.

More than half of cases reported mild acanthosis, mild spongiosis, exocytosis of lymphocytes, mild subepidermal edema, extravasation of erythrocytes, and a superficial and deep mixed inflammatory cell infiltrate of moderate intensity with interstitial eosinophils. Four subtypes are described: lymphocytic, eosinophilic, neutrophilic, and mixed. The authors conclude that type I hypersensitivity reaction is part of the pathogenesis of papular urticaria based on immunohistochemical evidence.

Differential Th1/Th2 balance in peripheral blood lymphocytes from patients suffering from flea bite-induced papular urticaria

Cuellar A, Rodriguez A, Rojas F, Halpert E, Gomez A, Garcia E. Allergol Immunopathol 2009; 37: 7–10.

Compared with age-matched healthy controls, 18 pediatric patients

with papular urticaria had a lower frequency of Interferon- γ -producing CD4⁺ T cells and a higher frequency of IL-4-producing CD4⁺ T cells.

Specific pattern of flea antigen recognition by IgG subclass and IgE during the progression of papular urticaria caused by flea bite

Cuéllar A, Rodríguez A, Halpert E, Rojas F, Gómez A, Rojas A, et al. *Allergol Immunopathol* 2010; 38: 197–202.

Among children clinically diagnosed with papular urticaria caused by flea bites, those who had 2 to 5 years of symptoms responded to flea antigen with higher IgE bands than those who had a shorter or longer duration of symptoms. In addition, healthy controls responded to flea antigen with IgG1 and IgG3 rather than IgE.

Both immediate and delayed-type hypersensitivity reactions are thought to be involved.

First-Line Therapies

• Elimination of arthropod	D
• Antihistamines	A
• Topical steroids	D
• Topical antipruritics (e.g., camphor/menthol, calamine lotion, crotamiton, lidocaine, and pramoxine)	E

Papular urticaria in children

Howard R, Frieden IJ. *Pediatr Dermatol* 1996; 13: 246–9.

Definitive treatment is elimination of the arthropod source. Pets must be treated with insecticidal shampoos and be well groomed. Carpets, rugs, and cloth furniture should be thoroughly vacuumed and the vacuum bag should be disposed, as eggs could fall off the pet onto these surfaces. Fumigation of fleas should include outdoor areas that the pet frequents. Veterinarians and professional exterminators should be called upon when necessary.

Dermatologic infestations

Shmidt E, Levitt J. *Int J Dermatol* 2012; 51: 131–41.

Removal and avoidance of the offending arthropod is the best treatment. Preventive measures include use of insect repellents such as

DEET and control of parasites infesting indoor pets. Empiric therapy with permethrin cream 5% or malathion lotion 0.5% is recommended. Anti-inflammatory therapy with topical steroids and control of pruritus with topical or oral antihistamines are discussed. A topical antibiotic such as mupirocin is recommended for impetiginized lesions.

Zoonoses of dermatologic interest

Parish LC, Schwartzman RM. *Semin Dermatol* 1993; 12: 57–64.

Animal fleas not only infest the pet but also live in the rugs and floors, visiting the pet for blood meals; therefore, the pet should be treated with insecticides, and the house should be fumigated.

Tropical rat mite dermatitis

Theis J, Lavoipierre MM, LaPerriere R, Kroese H. *Arch Dermatol* 1981; 117: 341–3.

Six cases of papular urticaria caused by the tropical rat mite (*Ornithonyssus bacoti*) are presented. Rodents were present in or around the home in most cases.

Effectiveness of bed bug monitors for detecting and trapping bed bugs in apartments

Wang C, Tsai WT, Cooper R, White J. *J Econ Entomol* 2011; 104: 274–8.

Authors compared the effectiveness of three bed bug-monitoring devices containing CO₂ as an attractant. A homemade dry ice trap was most effective, followed by the Cimex Detection Case (CDC3000) and then NightWatch; however, when NightWatch was used on consecutive nights, its efficacy increased. This study also confirmed the efficacy of Interceptor, an attractant-less monitoring system.

Evaluation of four bed bug traps for surveillance of the brown dog tick (*Acarix ixodidae*)

Carnohan LP, Kaufman PE, Allan SA, Gezan SA, Weeks EN. *J Med Entomol* 2015; 52: 260–8.

NightWatch and CO₂-baited ClimbUp traps were more effective than other trapping systems in capturing brown dog ticks.

Ability of bed bug-detecting canines to locate live bed bugs and viable bed bug eggs

Pfiester M, Koehler PG, Pereira RM. J Econ Entomol 2008; 101: 1389–96.

In a controlled experiment set-up in hotel rooms, the dogs were able to detect bed bugs with 98% accuracy.

Lethal effects of heat and use of localized heat treatment for control of bed bug infestations

Pereira RM, Koehler PG, Pfiester M, Walker W. J Econ Entomol 2009; 102: 1182–8.

Heat treatment of furniture for 2 to 7 hours at 49°C using equipment that costs less than \$400 can successfully disinfect furniture.

Gaseous chlorine dioxide as an alternative for bedbug control

Gibbs SG, Lowe JJ, Smith PW, Hewlett AL. Infect Control Hosp Epidemiol 2012; 33: 495–9.

At all concentrations tested (362, 724, and 1086 ppm), chlorine dioxide resulted in 100% mortality of bedbugs 18 hours after the exposure. These concentrations can be safely achieved in a hospital room.

In conjunction with chemical treatment of the home, the following strategies can be used to prevent further infestation: a sealed, plastic cover for the mattress; moving the mattress away from the wall; keeping blankets off the floor; petrolatum applied to the legs of the bed; plastic cups with or without water under the legs of the beds; white sheets to make the bed bugs or blood more visible; removing loose wallpaper; and filling in cracks of floorboards, furniture, walls, and windowsills. To prevent infection while traveling, travelers should examine the bed and area around the bed, avoid using hotel drawers, keep suitcases zipped, and launder clothes with heated drying upon return.

Comparison of cetirizine, ebastine and loratadine in the treatment of immediate mosquito-bite allergy

Karppinen A, Kautiainen H, Petman L, Burri P, Reunala T. Allergy 2002; 57: 534–7.

A double-blind, placebo-controlled, crossover study compared prophylactic administration of daily cetirizine 10 mg, ebastine 10 mg, and loratadine 10 mg in 29 adults with mosquito bites. Cetirizine and ebastine significantly reduced the size of wheals and pruritus. Cetirizine was found to be most effective against pruritus but more

sedative than ebastine and loratadine.

Levocetirizine for treatment of immediate and delayed mosquito bite reactions

Karppinen A, Brummer-Korvenkontio H, Petman L, Kautiainen H, Herve JP, Reunala T. *Acta Derm Venereol* 2006; 86: 329–31.

A double-blind, placebo-controlled, crossover study with levocetirizine 5 mg daily in 28 adults sensitive to mosquito bites. Patients were given the study drug for 4 days and exposed to mosquito bites on day 3. Levocetirizine reduced the size of wheals by 60% and pruritus by 62% compared to placebo.

Papular urticaria

Millikan LE. *Semin Dermatol* 1993; 12: 53–6.

Prevent papular urticaria by using repellents containing DEET if repeated exposure is suspected. Use antipruritics, including menthol, camphor, and pramoxine, for pruritus.

Second-Line Therapies

• Intralesional steroids	E
• Oral steroids	E
• DEET	E

Insect bite-induced hypersensitivity and the SCRATCH principles: a new approach to papular urticaria

Hernandez RG, Cohen BA. *Pediatrics* 2006; 118: 189–96.

Authors advocate the use of intralesional steroids in older children and adults to suppress pruritus if more conservative measures fail.

The role of dexamethasone in papular urticaria

El-Nasr NS. J Egypt Med Assoc 1961; 44: 340–1.

Dexamethasone 0.25 mg PO twice or three times daily for 1 to 2 weeks was used with good results. Pruritus resolved within 48 hours.

Comparative activity of three repellents against bedbugs *Cimex hemipterus*

Kumar S, Prakash S, Rao KM. Indian J Med Res 1995; 102: 20–3.

DEET, diethyl phenyl-acetamide (DEPA), and dimethyl phthalate (DMP) were tested against bedbugs on the shaven skin of rabbits. DEET was superior to the other two repellents at all concentrations tested. At 75% concentration, DEET showed 85% repellency for up to 2 hours and 52% repellency 6 hours after treatment.

Insect repellents: an overview

Brown M, Hebert AA. J Am Acad Dermatol 1997; 36: 243–9.

DEET was highly effective at repelling mosquitoes, biting fleas, gnats, chiggers, and ticks. Permethrin works as both an insecticide and a repellent against lice, ticks, fleas, mites, mosquitoes, and black flies.

Third-Line Therapies

• Phototherapy	E
• Ciclosporin	E
• Hospitalization	E

Papular dermatitis in adults: subacute prurigo, American style?

Sherertz EF. J Am Acad Dermatol 1991; 24: 697–702.

Twelve patients with pruritic papular eruptions were followed, and

the majority were refractory to conservative symptomatic management but showed some control with oral steroids, ultraviolet B (UVB), or psoralen and ultraviolet A radiation (PUVA) treatment.

Papular urticaria and transfer of allergy following bone marrow transplantation

Smith SR, Macfarlane AW, Lewis-Jones MS. Clin Exp Dermatol 1988; 13: 260–2.

A 20-year-old male who underwent allogeneic bone marrow transplant developed papular urticaria as a result of transfer of allergy from the donor. Upon withdrawal of ciclosporin, the patient developed a papular eruption. This suggests a suppressive effect of ciclosporin on papular urticaria.

Papular urticaria

Rook A, Frain-Bell W. Arch Dis Child 1953; 28: 304–10.

Multiple cases of papular urticaria are reported where the eruption cleared when patients were hospitalized. Hospitalization removes the patient from the arthropod source of papular urticaria and allows for sufficient time to rid the home of the arthropods before the patient returns home.

Paracoccidioidomycosis (South American blastomycosis)

Wanda Sonia Robles, and Mahreen Ameen

Paracoccidioidomycosis (PCM) is a chronic, progressive, granulomatous mycosis caused by the dimorphic fungus *Paracoccidioides brasiliensis*. It primarily affects the lungs and is

believed to be acquired from inhalation of the fungus that resides in soil and plants of endemic regions. PCM is restricted to Latin America, where it is the most prevalent systemic endemic mycosis. It has been reported in nearly all countries from Mexico to Argentina, with the exception of the Caribbean islands and Chile. Eighty percent of cases occur in Brazil, with the highest incidence in the state of Sao Paulo. This is followed by Venezuela, Colombia, Ecuador, and Argentina. PCM characteristically affects those working in agriculture and in rural areas. Because of the long latency period, the disease may appear many years after a person has left an endemic region. Untreated PCM has one of the highest rates of mortality of all the systemic mycoses.

There are two main clinical forms: an acute or subacute form, and a unifocal or multifocal chronic form. The acute form affects young people of both sexes and involves mainly the reticuloendothelial system. This form of infection is often severe and carries a worse prognosis. The chronic form most commonly affects adult males and causes pulmonary and/or mucocutaneous disease. Most cases of pulmonary infection have an indolent course. Only 2% of those infected develop the disseminated form of disease. Dissemination occurs most commonly to the mucosae of the upper airways and upper gastrointestinal tract. Cutaneous and lymph node involvement is common, and other organ systems may be involved such as the adrenal glands (causing Addison syndrome), bones, and central nervous system. Oral lesions affect the gingivae, the hard palate, lips, and tongue. Nasal and pharyngeal ulcers can give rise to dysphagia and dysphonia. Ulcerative lesions can be painful and are characterized by a punctate vascular pattern over a granulomatous base. Cutaneous lesions are highly polymorphic, consisting of verrucous and ulcerative papules, plaques, and nodules. Centrofacial localization is typical and usually a result of dissemination of oral lesions. PCM is also characterized by massive and visible cervical and submandibular lymphadenopathy, which may progress to form abscesses with draining sinuses. Other lymph glands may also become enlarged. Primary mucocutaneous infection is rare, but can occur after direct inoculation of the skin or mucous membranes. It can arise from using twigs to clean the teeth, which is practiced in rural Brazil.

Disseminated infection is severe in the immunocompromised, including those coinfecting with HIV. The mortality rate with HIV

infection is high, ranging from 30% to 45%. However, the incidence of PCM in patients with AIDS in Latin America is low, and this has been attributed to the widespread use of trimethoprim–sulfamethoxazole as prophylaxis for *Pneumocystis carinii* pneumonia.

Management Strategy

P. brasiliensis is highly sensitive to antifungal drugs, and therefore a large therapeutic armamentarium exists to treat PCM. *Itraconazole* is the drug of choice for the treatment of mild to moderate acute and chronic clinical forms of PCM. It is given at a dose of 100 to 200 mg daily for a mean period of 6 months (range 3–12 months) depending on clinical response. It gives a cure rate of 90%, and recurrence rates of 0% to 15% have been reported after a median of 12 months, depending on comorbidities such as alcoholism, malnutrition, and AIDS. *Ketoconazole* (200–400 mg daily) is also highly effective, with 90% of patients responding after 6 to 12 months of treatment with only a 10% relapse rate. However, adverse effects are common especially with long-term treatment. With the availability of newer antifungals, its use has decreased. *Sulfonamides* (sulfadiazine, sulfamethoxypyridazine, sulfadimethoxine, trimethoprim–sulfamethoxazole) are an attractive option as they are inexpensive and well tolerated. However, therapy duration is characteristically long, usually 2 to 3 years. Compliance can therefore be a problem, which might explain their lower cure rate of only 70%. In addition, they have a significant relapse rate of 35%. They are still commonly used as first agents in endemic regions because of their ready availability and low cost. Parenteral *amphotericin B* (cumulative dose of 1–2 g based on clinical response) is the drug of choice for severe or refractory infection. The cure rate is only 60%, but consideration must be given to the fact that it is usually given to the most severely ill patients. The relapse rate with amphotericin B is generally higher than with *itraconazole*, occurring in 20% to 30% of cases. Long-term maintenance therapy with an azole or sulfonamide is therefore required. In cases of central nervous system (CNS) PCM, sulfadiazine appears to be equally effective as amphotericin B. Recently *voriconazole*, an extended-spectrum triazole, has demonstrated comparable efficacy and tolerability to itraconazole in the treatment of PCM. However, its high costs make it prohibitive for use in most endemic settings. There are few studies demonstrating the efficacy of

fluconazole for PCM. It has been suggested that it may be useful in the management of CNS PCM given its excellent CNS penetration. Long-term follow-up after treatment of PCM is required, as relapse rates are unknown. More recently the use of amphotericin B lipid complex has been advocated.

Specific Investigations

- Direct microscopy
- Culture
- Histology
- Serologic tests
- Chest radiography
- Serology for HIV/AIDS infection (where relevant)

Rapid diagnosis may be achieved by direct microscopic examination of sputum or other exudates in potassium hydroxide. *P. brasiliensis* appears as large, round yeast cells with multiple budding. Culture of sputum, skin, lymph node, or bone marrow specimens on Sabouraud dextrose agar can recover the organism, but may require 20 to 30 days for growth. Biopsy specimens reveal granuloma formation, and Gomori methenamine silver stain reveals yeast cells. Several serologic tests detect antibodies against the fungus, and they can provide results earlier than culture or histopathology. The most common test is immunodiffusion, which has high specificity, but sensitivity varies depending on the type of antigen used. Therefore a negative serologic response does not exclude PCM, particularly in the immunocompromised.

Paracoccidioidomycosis and AIDS: an overview

Goldani L, Sugar AM. Clin Infect Dis 1995; 21: 1275–81.

This is the largest published review of paracoccidioidomycosis in association with AIDS. A wide spectrum of clinical manifestations was seen in the 27 patients described, ranging from indolent infection to rapidly progressive disease. There was multiorgan involvement in 70.4% of patients ($n = 19$), with disseminated disease being the most common form of paracoccidioidomycosis. The overall mortality among patients with AIDS is high (30%). The prognosis can be improved by earlier diagnosis and aggressive therapy with amphotericin B, followed by lifelong suppressive therapy with

trimethoprim–sulfamethoxazole.

Paracoccidioidomycosis in patients with human immunodeficiency virus: review of 12 cases observed in an endemic region in Brazil

Paniago AM, de Freitas AC, Aguiar ES, Aguiar JI, da Cunha RV, Castro AR, et al. *J Infect* 2005; 51: 248–52.

This study demonstrated that the lymph nodes were the organ most commonly involved ($n = 10$, 83.3%), followed by the lung ($n = 7$, 58.3%). Papulonodular ulcerative skin lesions affected 50% ($n = 6$), and oral mucosal ulcerative lesions were present in 42% ($n = 5$). A single patient had pleural involvement with a secondary pathologic rib fracture. Seven patients had multiorgan involvement. All patients were treated with trimethoprim–sulfamethoxazole, and seven patients in addition received amphotericin B. However, eight patients (67%) died as a result of disease progression.

Pharmacologic management of paracoccidioidomycosis

Yasuda MA. *Expert Opin Pharmacother* 2005; 6: 385–97.

This article emphasizes the long duration of drug therapy required for both the treatment and maintenance of patients with severe infection. It explores the possibility of finding novel therapies among new classes of drugs, drug combinations, or agents capable of modulating the immune response, such as a peptide derived from the 43 kDa *P. brasiliensis* glycoprotein.

Drugs for treating paracoccidioidomycosis

Menezes VM, Soares BG, Fontes CJ. *Cochrane Database Syst Rev* 2006; 19: CD004967.

This was a critical evaluation of the current therapeutic armamentarium used for the treatment of paracoccidioidomycosis. On the basis of strict selection criteria, including randomized controlled trials, only a single study could be included for analysis (Shikanai-Yasuda MA et al., 2002) with a brief mention of other studies.

Treatment options for paracoccidioidomycosis and new strategies investigated

Travassos LR, Taborda CP, Colombo AL. *Expert Rev Anti Infect Ther* 2008; 6: 251–62.

This article highlights the significant and unresolved burden of relapses despite the use of long courses of drug therapies, which include sulfamethoxazole–trimethoprim, itraconazole, and amphotericin B. A peptide vaccine aimed at immunotherapy of paracoccidioidomycosis is being studied, and the authors suggest that it could be used as a vaccine to reduce the duration of chemotherapy and the risk of relapse.

Paracoccidioidomycosis

Ramos-E-Silva M, Saraiva Ldo E. *Dermatol Clin* 2008; 26: 257–69.

This review is written with dermatologists in mind, with a focus on the features of mucocutaneous presentation.

Central nervous system paracoccidioidomycosis: an overview

De Almeida SM. *Braz J Infect Dis* 2005; 9: 126–33.

CNS involvement with paracoccidioidomycosis has been found in 13% of patients with systemic disease. This review article covers the clinical presentation, diagnostic tests, and treatments for CNS infection. Sulfas are considered the drugs of choice, with sulfamethoxazole–trimethoprim (160/800 mg three times daily) being most commonly used. Amphotericin B is only used in cases of resistance or intolerance to sulfonamides. Of the azoles, itraconazole and particularly ketoconazole penetrate the blood–brain barrier poorly. Fluconazole, however, has excellent CNS penetration, making it a potentially suitable alternative to the other drug therapies.

Amphotericin B lipid complex in the treatment of severe paracoccidioidomycosis: a case series

Peçanha PM, de Souza S, Falqueto A, Grão-Veloso TR, Lírio LV, Ferreira CU Jr, et al. *Int J Antimicrob Agents* 2016; 48: 428–30.

First report of amphotericin B lipid complex (ABLC) used in the treatment of paracoccidioidomycosis with a cure rate of 100% in 28 patients.

First-Line Therapies

• Itraconazole	B
• Sulfonamides	B
• Amphotericin B	B

Treatment of paracoccidioidomycosis with itraconazole

Naranjo MS, Trujillo M, Munera MI, Restrepo P, Gomez I, Restrepo A. J Med Vet Mycol 1990; 28: 67–76.

Forty-seven patients with mainly the chronic adult form of infection were treated with itraconazole 100 mg daily for a mean treatment period of 6 months (range 3–24 months). There was marked clinical improvement in 43 patients (89%) and complete resolution of disease in only 1 patient. The mycologic tests (direct examination and cultures) became negative during the first month of treatment in 87% of patients, and by the end of treatment there was a decline in specific antibody titers in 72% of patients. There was no clinical relapse in 15 patients during a 12-month follow-up period.

Randomized trial with itraconazole, ketoconazole and sulfadiazine in paracoccidioidomycosis

Shikanai-Yasuda MA, Benard G, Higaki Y, Del Negro GM, Hoo S, Vaccari EH, et al. Med Mycol 2002; 40: 411–7.

This study from Brazil included 42 patients with moderately severe paracoccidioidomycosis. They were randomized to receive itraconazole 50 to 100 mg daily ($n = 14$), ketoconazole 200 to 400 mg daily ($n = 14$), or sulfadiazine 150 mg/kg daily ($n = 14$) for an induction period of 4 to 6 months. This was followed by slow-release sulfa (sulfamethoxypyridazine) until negative serologic results were obtained. The majority of patients in all arms were reported as cured after 6 months of treatment, and antibody levels reduced significantly by 10 months of treatment for all three drugs.

This study demonstrated that both sulfadiazine and the azoles were

equally effective, and the cure rates for the individual drugs were similar to previous studies.

Paracoccidioidomycosis in children: clinical presentation, follow-up and outcome

Pereira RM, Bucaretychi F, Barison Ede M, Hessel G, Tresoldi AT. Rev Inst Med Trop Sao Paulo 2004; 46: 127–31.

This study from Brazil investigated 70 episodes of infection in 63 children under the age of 15 years (range 2–15 years). The juvenile and disseminated form of paracoccidioidomycosis was seen in 70% of episodes, most of them presenting with a febrile lymphoproliferative syndrome. The diagnosis was confirmed by lymph node biopsy (84%), bone biopsy (9%), and skin biopsy (7%). Treatment consisted of either sulfamethoxazole–trimethoprim monotherapy ($n = 50$), sulfamethoxazole–trimethoprim combined with amphotericin B ($n = 9$), or ketoconazole ($n = 5$). Follow-up revealed significant sequential improvement 1 and 6 months later. However, six patients died (9.3%) and four developed sequelae: portal hypertension in three and hypersplenism in one (6.3%). The authors attribute the deaths to the severity of disseminated infection in the context of profound immunosuppression caused by paracoccidioidomycosis as well as malnutrition. A long period of drug treatment, up to 2 years, is required in order to prevent any risk of relapse.

The authors suggest sulfamethoxazole–trimethoprim as first-line therapy in children because of its efficacy, low cost, and easy route of oral administration. It may also be infused intravenously for severe infection. They attributed therapy failure largely to noncompliance.

Paracoccidioidomycosis: a clinical and epidemiological study of 422 cases observed in Mato Gross do Sul

Paniago AM, Aguiar JI, Aguiar ES, da Cunha RV, Pereira GR, Londero A, et al. Rev Soc Bras Med Trop 2003; 36: 455–9.

In terms of treatment this paper illustrates how sulfamethoxazole–trimethoprim is commonly used in endemic areas for paracoccidioidomycosis; 90.3% of patients were treated with this drug, with the majority responding to treatment.

Clinical and serologic features of 47 patients with paracoccidioidomycosis treated by amphotericin B

De Campos EP, Sartori JC, Hetch ML, de Franco MF. Rev Inst Med

Trop Sao Paulo 1984; 26: 212–7.

In this study of 47 patients with disseminated infection treated with amphotericin B (3 mg/kg, total dose of 2.0–3.0 g), clinical and serologic cure was obtained in 54% of patients.

Paracoccidioidomycosis: a comparative study of the evolutionary serologic, clinical and radiologic results for patients treated with ketoconazole or amphotericin B plus sulfonamides

Marques SA, Dillon NL, Franco MF, Habermann MC, Lastoria JC, Stolf HO, et al. Mycopathologia 1985; 89: 19–23.

This was a retrospective study comparing the use of ketoconazole (400 mg daily for 30 days followed by 200 mg daily for 18 months) in 22 patients against amphotericin B (1.5–1.75 mg/kg/day for 30–60 days) together with sulfonamide maintenance therapy for up to 18 months in 32 patients. Approximately one third of patients in each group had the acute form of the infection, and the rest had chronic disease. Patients treated with ketoconazole demonstrated better responses, but the results were not statistically significant. There was a sharper drop in antibody titers in patients treated with ketoconazole, but there was no difference in radiologic evolution between the treatments.

Failure of amphotericin B colloidal dispersion in the treatment of paracoccidioidomycosis

Dietze R, Fowler VG Jr, Steiner TS, Pecanha PM, Corey GR. Am J Trop Med Hyg 1999; 60: 837–9.

In this study four adults with the aggressive juvenile form of paracoccidioidomycosis were treated with amphotericin B colloidal dispersion. One patient was also coinfectd with HIV. They all received a dose of 3 mg/kg/day for at least 28 days. Three patients, including the HIV-infected case, demonstrated a complete clinical response, but relapsed within 6 months. They were subsequently successfully treated with cotrimoxazole. The authors suggest possible reasons for failure might have been the dose, treatment duration, the drug formulation, inadequate drug delivery to sites of infection, and impaired host immunity. The authors also describe unpublished data on five further patients with chronic paracoccidioidomycosis treated with liposomal amphotericin 4 mg/kg/day. They also responded to treatment initially, but subsequently relapsed after treatment was stopped.

These results raise concerns about the use of short courses of lipid-based formulations to treat PCM. Further and larger studies are required to investigate their efficacy.

Paracoccidioidomycosis: epidemiological, clinical, diagnostic and treatment up-dating

Marques SA. An Bras Dermatol 2013; 88: 700–11.

A very good review article that outlines the treatment of paracoccidioidomycosis with itraconazole, sulfamethoxazole–trimethoprim, and amphotericin B as first-line interventions.

Paracoccidioidomycosis in Mexico: clinical and epidemiological data from 93 new cases (1972-2012)

López-Martínez R, Hernández-Hernández F, Méndez-Tovar LJ, Manzano-Gayosso P, Bonifaz A, Arenas R, et al. 2014; 57: 525–30.

This very good review article reports itraconazole alone and the combination of itraconazole with sulfamethoxazole–trimethoprim as the most effective treatment.

Second-Line Therapies

• Ketoconazole	B
• Fluconazole	B
• Voriconazole	B
• Terbinafine	E

Treatment of paracoccidioidomycosis with ketoconazole: a three-year experience

Restrepo A, Gómez I, Cano LE, Arango MD, Gutiérrez F, Sanín A, et al. Am J Med 1983; 74: 48–52.

Thirty-eight patients with active infection were treated with ketoconazole 200 mg daily for 6 months. Treatment was well tolerated. There was complete resolution of infection in 13 patients (34%) and significant improvement in the majority of the rest of the patients.

In a subsequent study, 24 of these patients were followed up for a 1- to 2-year period. Relapse was detected in only two patients. There are no recent studies evaluating ketoconazole for PCM, as its use has declined with the advent of newer antifungals.

A pan-American 5-year study of fluconazole therapy for deep mycoses in the immunocompetent host. Pan-American Study Group

Diaz M, Negroni R, Montero-Gei F, Castro LG, Sampaio SA, Borelli D, et al. Clin Infect Dis 1992; 14 (Suppl 1): S68–76.

Twenty-seven of 28 patients responded to treatment with fluconazole 200 to 400 mg daily given for at least 6 months. Treatment was well tolerated. However, relapse was noted in one patient within the first year.

This is the only reported study of fluconazole therapy for PCM. A longer period of follow-up is required in order to evaluate drug efficacy.

An open-label comparative pilot study of oral voriconazole and itraconazole for long-term treatment of paracoccidioidomycosis

Queiroz-Telles F, Goldani LZ, Schlamm HT, Goodrich JM, Espinel-Ingroff A, Shikanai-Yasuda MA. Clin Infect Dis 2007; 45: 1462–9.

This multicenter study from Brazil investigated the efficacy, safety, and tolerability of voriconazole for the long-term treatment of acute or chronic paracoccidioidomycosis, with itraconazole as the control treatment. Patients were randomized (at a 2:1 ratio) to receive oral voriconazole ($n = 35$) or itraconazole ($n = 18$) for 6 to 12 months. Voriconazole was given at an initial loading dose of 800 mg in divided doses on day 1, followed by 200 mg twice daily. The dose of itraconazole was 100 mg twice daily. There was a satisfactory response rate in 88.6% of the voriconazole group and 94.4% of the itraconazole group. The response rate among treatment-evaluable

patients was 100% for both treatment groups. No relapses were observed after 8 weeks of follow-up. Both drugs were well tolerated, although liver function test values were slightly higher in patients receiving voriconazole, necessitating the withdrawal of voriconazole from two patients.

This study has demonstrated equal efficacy and tolerability of oral voriconazole and itraconazole for the long-term treatment of paracoccidioidomycosis. This study also included a case of CNS paracoccidioidomycosis that responded to treatment. Voriconazole demonstrates good CNS penetration, having been successfully used in the treatment of other mycotic CNS infections. On the basis of these results the authors suggested that intravenous voriconazole should be evaluated as an alternative to amphotericin B for the initial treatment of severe paracoccidioidomycosis, given the high relapse rate and toxicity associated with amphotericin B therapy.

Chronic paracoccidioidomycosis in a female patient in Austria

Mayr A, Kirchmair M, Rainer J, Rossi R, Kreczy A, Tintelnot K, et al. Eur J Clin Microbiol Infect Dis 2004; 23: 916–9.

Case report of a Cuban female patient who was initially misdiagnosed with tuberculosis. She was successfully treated with amphotericin B (1 mg/kg/day) for 10 days followed by voriconazole 200 mg daily for 3 months.

Paracoccidioidomycosis (South American blastomycosis) successfully treated with terbinafine: first case report

Ollague JM, de Zurita AM, Calero G. Br J Dermatol 2000; 143: 188–91.

A case report of a 63-year-old male who presented with lesions of paracoccidioidomycosis in the perineal region. Initial treatment with trimethoprim–sulfamethoxazole failed. He was subsequently treated with terbinafine 250 mg twice daily for 6 months, which resulted in rapid resolution of all lesions without evidence of relapse for 2 years after treatment.

Terbinafine has demonstrated similar activity to itraconazole against P. brasiliensis in vitro.

Isavuconazole treatment of cryptococcosis and dimorphic mycoses

Thompson GR 3rd, Rendon A, Ribeiro Dos Santos R, Queiroz-Telles F, Ostrosky-Zeichner L, Azie N, et al. Clin Infect Dis 2016; 63: 356–62.

An open-label, nonrandomized, phase III trial to evaluate efficacy and safety of isavuconazole in the management of invasive fungal infections. Thirty-eight patients, of which 10 had paracoccidioidomycosis, received this treatment. The study reports that 63% of the total of patients had an overall successful response.

Parapsoriasis

James E. Miller, and Graham A. Johnston

The use of the description parapsoriasis, even as an umbrella term, remains controversial, and debate remains whether the variants described in this chapter are in fact precursors of cutaneous T-cell lymphoma (CTCL). This chapter covers the entities small plaque parapsoriasis (SPP), which includes the synonyms chronic superficial scaly dermatitis, persistent superficial dermatitis, digitate dermatosis,

and xanthoerythroderma perstans, and large plaque parapsoriasis (LPP), which includes the synonyms parakeratosis variegata, retiform parapsoriasis, atrophic parapsoriasis, and poikilodermatous parapsoriasis. Confusingly, the term *parapsoriasis en plaque* has been used for both SPP and LPP.

Parapsoriasis is often grouped with other cutaneous lymphoproliferative disorders, including pityriasis lichenoides et varioliformis acuta, pityriasis lichenoides chronica, lymphomatoid papulosis, and mycosis fungoides, all of which are the subjects of separate chapters.

Management Strategy

Although the diagnosis of parapsoriasis is initially considered on clinical grounds, histopathologic examination, with T-cell receptor gene rearrangement studies, is essential to exclude monoclonality and CTCL. However, monoclonality is not sensitive or specific for CTCL. Monoclonality has been identified in SPP, but it is reported more often in LPP. This does not appear to predict the risk of progression to CTCL. Regular repeat skin biopsies are recommended if a clinical or histologic progression to CTCL is suspected.

Although topical therapy is appropriate in mild or early cases, the potential for progression to cutaneous lymphoma in patients with parapsoriasis can justify the use of phototherapy in symptomatic or progressive cases.

Specific Investigations

- The diagnosis is initially suspected on clinical findings
- Histology is nonspecific but differs between small and large plaque types
- T-cell receptor (TCR) gene rearrangement studies can identify T-cell clones

Immunohistochemistry cannot differentiate between small and large plaque parapsoriasis.

Clonal T cell receptor gamma-chain gene rearrangement by PCR-based GeneScan analysis in the skin and blood of patients with

parapsoriasis and early-stage mycosis fungoides

Klemke CD, Dippel E, Dembinski A, Pönitz N, Assaf C, Hummel M, et al. *J Pathol* 2002; 197: 348–54.

Although the authors of this paper concede that studies have shown T-cell clonality in both skin and peripheral blood, they argue that monoclonality is neither easily demonstrable nor ought to be a prerequisite for diagnosis.

The role of immunohistochemical analysis in the diagnosis of parapsoriasis

Bordignon M, Belloni-Fortina A, Pigozzi B, Saponeri A, Alaibac M. *Acta Histochem* 2011; 113: 92–5.

Given the lack of clinical and histologic markers of distinction between parapsoriasis and early CTCL, the use of immunohistochemical techniques has been explored to try to establish a more definitive diagnosis. However these techniques, including CD4/CD8 ratio, expression of T-cell antigens, and expression of proliferation markers, have been found unhelpful in distinguishing between parapsoriasis and early CTCL.

Defining early mycosis fungoides

Pimpinelli N, Olsen EA, Santucci M, Vonderheid E, Haeffner AC, Stevens S, et al. *J Am Acad Dermatol* 2005; 53: 1053.

To aid in the diagnosis of early CTCL an algorithm was devised by the International Society for Cutaneous Lymphomas (ISCL) encompassing clinical, histopathologic, immunohistochemistry, and T-cell gene arrangement characteristics. The study was proposed to validate the algorithm using a 4-point threshold. They found the algorithm to be statistically valid, but it was limited by a sensitivity of 87.5% and an even lower specificity at 60%. The authors felt that until sensitivity and specificity improved, existing clinicopathologic correlation will remain the gold standard.

Small Plaque Parapsoriasis

SPP consists of fixed, scaly erythematous plaques less than 5 cm in diameter. They are predominantly asymptomatic but can be mildly pruritic and occur mainly on the trunk and proximal extremities. The lesions sometimes appear to run in fingerlike lines parallel to the ribs

(hence the synonym digitate dermatosis). Histology shows mild spongiosis with focal parakeratosis and small areas of perivascular lymphocytic infiltrate within the papillary dermis. SPP runs a chronic, indolent, and usually benign course.

First-Line Therapies

• Emollients, tar, topical corticosteroids	E
• Psoralen Ultraviolet A treatment	C
• Narrowband Ultraviolet B	C

Treatments with emollients, topical tar, and topical corticosteroid are widely used, but evidence is anecdotal and these treatments are therefore unreferenced.

Narrowband UVB phototherapy for small plaque parapsoriasis

Aydogan K, Karadogan SK, Tunalı S, Adım SB, Özcelik T. J Eur Acad Dermatol Venereol 2006; 20: 573–7.

Forty-five patients were treated with narrowband UVB therapy three to four times weekly. There was a complete response in 33 patients with a mean cumulative dose of 14.3 J/cm² after a mean number of 29 exposures. There was a partial response in 12 of the 45. Relapses occurred in 6 of the 45 patients within a mean of 7.5 months.

Treatment of small plaque parapsoriasis with narrow-band (311 nm) ultraviolet B: a retrospective study

Herzinger T, Degitz K, Plewig G, Rocken M. Clin Exp Dermatol 2005; 30: 379–81.

Sixteen patients had complete remission after a mean number of 33 exposures and a mean total dose of 35.4 J/cm². Relapse occurred after an average of 29 weeks showing similarity with the study by Aydogan et al.

Narrowband (311-nm) UV-B therapy for small plaque parapsoriasis and early-stage mycosis fungoides

Hofer A, Cerroni L, Kerl H, Wolf P. Arch Dermatol 1999; 35: 1377–80.

Fourteen patients with SPP were treated with narrowband UVB, three to four times weekly for 5 to 10 weeks. Complete response was achieved after an average of 20 exposures. All patients then relapsed after an average of 6 months. Topical corticosteroids were effective at producing a second clearance in an unspecified number of patients.

Retrospective study of 24 patients with large or small plaque parapsoriasis treated with ultraviolet B therapy

Arai R, Horiguchi Y. J Dermatol 2012; 39: 674–6.

A retrospective study of 24 patients given UVB for both small and large plaque parapsoriasis. Five patients resolved with treatment over a median duration of 3.5 years. Eighteen continued with active disease, although this cohort had a median duration of 2 years of treatment. The findings suggest longer treatment is required to cause remission, although the values were not significant. One patient progressed from LPP to CTCL. The study suggests long-term phototherapy is of clinical benefit.

Treatment of parapsoriasis and mycosis fungoides: the role of psoralen and long-wave ultraviolet light A (PUVA)

Powell FC, Spiegel GT, Muller SA. Mayo Clin Proc 1984; 59: 538–46.

Seven patients with SPP had complete clearance with as few as 15 treatments (84 J/cm²) of standard PUVA. Three patients reported recurrence at follow-up (mean of 13 months), and one of these was then successfully treated with topical corticosteroid.

Second-Line Therapy

• Topical nitrogen mustard	C
----------------------------	---

Topical nitrogen mustard therapy in patients with mycosis fungoides or parapsoriasis

Lindahl LM, Fenger-Gron, M, Iversen L. J Eur Acad Dermatol Venereol 2013; 27: 163–8.

Seventy-one patients with parapsoriasis (no information on

numbers of LPP and SPP) were treated with mechlorethamine hydrochloride between 1991 and 2009. A dose of 20 mg was dissolved in 40 mL water and applied daily to affected skin for a 14-day induction period. Maintenance therapy of two treatments every 4 to 8 weeks occurred until clear, insufficient response or side effects developed. The “overall” response was 90%, with a “complete” response of 41%. Relapse (no time given) was 62%. The main side effect was contact dermatitis resulting in withdrawal of treatment in 14% of patients.

Large Plaque Parapsoriasis

This is clinically similar to SPP but lesions are larger than 5 cm, irregularly shaped, and often atrophic or poikilodermatous. Lesions typically occur over the lower trunk and thighs.

Specific Investigations

- Skin biopsy
- TCR gene rearrangement studies

The diagnosis is suggested clinically. Histology demonstrates psoriasiform epidermal hyperplasia with areas of atrophy in poikilodermatous areas. There is vacuolization in the basal layer and a bandlike lymphocytic infiltrate in the papillary dermis. Pautrier microabscesses, a prominent feature of mycosis fungoides, are usually absent.

Progression of LPP to cutaneous T-cell lymphoma is reported, with one retrospective study demonstrating a figure of 35%. This same study also reported 10% of patients with SPP progressing to CTCL.

Large plaque parapsoriasis: clinical and genotypic correlations

Simon M, Flaig MJ, Kind P, Sander CA, Kaudewitz P. J Cutan Pathol 2000; 27: 57–60.

TCR gene rearrangement status was assessed in 12 patients. Six of 12 patients with LPP had a clonal T-cell population. One developed CTCL after a follow-up of 8 years. The other five patients did not progress after follow-up of 2 to 21 years.

The authors conclude that TCR gene rearrangement status has no

prognostic significance and does not allow distinction between LPP and early CTCL.

A retrospective study of the probability of the evolution of parapsoriasis en plaques into mycosis fungoides

Väkevä L, Sarna S, Vaalasti A, Pukkala E, Kariniemi AL, Ranki A. Acta Derm Venereol 2005; 85: 318–23.

A 26-year retrospective analysis of 105 patients with SPP and LPP reported that 10% of patients with SPP and 35% of patients with LPP progressed to histologically confirmed CTCL over a median time of 10 and 6 years, respectively.

Subsequent cancers, mortality and causes of death in patients with mycosis fungoides and parapsoriasis: a Danish nationwide, population-based cohort study

Lindahl LM, Fenger-Gron M, Iversen L. J Am Acad Dermatol 2014; 71: 529.

Using the Danish nationwide population-based registry, 368 mycosis fungoides and 582 parapsoriasis patients were compared with the general population for subsequent cancers, mortality, and causes of death. Subsequent cancers were significantly increased in the parapsoriasis group, including non-Hodgkin lymphoma (NHL), hematologic cancers other than NHL, and nonhematologic cancers, with the highest incidence being in the gastrointestinal (GI) tract. Interestingly the incidence of these malignancies was significantly higher within the first 5 years of diagnosis. In the mycosis fungoides group the only significantly increased cancer was NHL. Both groups had a significantly increased mortality compared with the general Danish population, with the mycosis fungoides group being more pronounced with the first 5 years of diagnosis.

First-Line Therapies

Topical steroids

• Ultraviolet A with 5-methoxypsoralen	C
• Ultraviolet A with 4,6,4'-trimethylangelicin	E

The use of topical steroids has not been evaluated in clinical trials, but its benefit has been observed in early-stage CTCL.

Photochemotherapy in cutaneous T cell lymphoma and parapsoriasis en plaque. Long-term follow-up in forty-three patients

Rosenbaum MM, Roenigk HH Jr, Caro WA, Esker A. *J Am Acad Dermatol* 1985; 13: 613–22.

Of the 43 patients included in the study 7 patients had LPP treated with oral psoralen and UVA (PUVA). A complete response was achieved in all 7, though the total dosages of PUVA are not stated. Average follow-up for all 43 patients was 38.4 months (range 4–67 months), and during that time relapse was observed in 5 out of the 7 patients with LPP.

The authors argue that because CTCL is in the differential diagnosis of LPP and PUVA is effective for both conditions, it may be useful in patients in whom it is difficult to distinguish between the two conditions.

Topical nitrogen mustard therapy in patients with mycosis or parapsoriasis

Lindahl LM, Fenger-Gron M, Iversen L. *J Eur Acad Dermatol Venereol* 2013; 27: 163–8.

Seventy-one patients with parapsoriasis (no information on numbers of LPP and SPP) were treated with mechlorethamine hydrochloride between 1991 and 2009. A dose of 20 mg was dissolved in 40 mL water and applied daily to affected skin for a 14-day induction period. Maintenance therapy of two treatments every 4 to 8 weeks occurred until clear, insufficient response or side effects developed. The “overall” response was 90%, with a “complete” response of 41%. Relapse (no time given) was 62%. The main side effect was contact dermatitis resulting in withdrawal of treatment in 14% of patients.

Evaluation of a 1-hour exposure time to mechlorethamine (chlormethine) in patients undergoing topical treatment

Foulc P, Evrard V, Dalac S, Guillot B, Delaunay M, Verret JL, et al. *Br J Dermatol* 2002; 147: 926–30.

Three patients with LPP were included in this study. One patient

stopped treatment because of the side effects, and two of the three resulted in complete remission. The mechlorethamine regimen, however, varied between the four centers included in the study and is not specified for the individual patient.

Paronychia

Richard B. Mallett, and Cedric C. Banfield

Paronychia is characterized by inflammation of the proximal and/or lateral nail folds, with the fingers being more commonly affected than the toes. Acute paronychia is a painful pyogenic infection that usually occurs after injury or minor trauma and is characteristically caused by *Staphylococcus aureus*, although other aerobic and anaerobic bacteria and herpetic viruses are also found.

Chronic paronychia, one of the most common inflammatory nail disorders, presents as tender erythema of the nail folds with thickening of the tissues, loss of the cuticle, and subsequent

dystrophy of the nail plate. The causative factors are repetitive microtrauma and exposure to water, irritants, and allergens, causing a contact dermatitis with subsequent colonization by yeasts and bacteria. Other less common causes of chronic paronychia include retronychia, characterized by the disruption of the longitudinal growth of a nail due to acute traumatic injury or repetitive microtrauma, with resultant embedding of the old nail in the ventral surface of the proximal nail fold as the new nail regenerates. Also, cutaneous leishmaniasis may rarely present as an unusual chronic paronychia in endemic areas. Pemphigus vulgaris may present with either acute or chronic paronychia.

Drug-induced paronychia with pseudopyogenic granuloma is increasingly recognized and may occur with systemic retinoids, antiretroviral drugs such as indinavir, epidermal growth factor (EGF) receptor inhibitors, including gefitinib and cetuximab, and the novel anticancer mechanistic Target Of Rapamycin mTOR inhibitors such as everolimus.

Tumors, including Bowen's disease, keratoacanthomas, squamous cell carcinoma, enchondroma, and amelanotic melanoma, may masquerade as chronic paronychia. Dermoscopy has been used to diagnose periungual Bowen's disease mimicking chronic paronychia.

Management Strategy

Acute paronychia requires urgent effective treatment to prevent damage to the nail matrix. If the infection is superficial and pointing, then *incision and drainage* may be appropriate. Infection is often due to *S. aureus*, but β -hemolytic streptococci and anaerobic organisms may also be found. A swab must be taken for bacterial culture and antibiotic sensitivity and a *broad-spectrum antibiotic* covering both aerobic and anaerobic organisms given. *Warm compresses with an astringent* (e.g., aluminum acetate lotion, if available) can help reduce edema and provide a hostile environment for bacteria. For deeper infections, if there has been no marked clinical improvement after 48 hours of antibiotic therapy, *surgical treatment* may be undertaken. Under local anesthesia, the proximal third of the nail plate is removed, and a gauze wick is laid under the proximal nail fold to allow drainage. Cases of antibiotic-resistant acute paronychia may be due to herpetic viruses, fungi, or noninfectious causes.

Chronic paronychia is usually due to dermatitis and often

associated with wet work (e.g., in domestic workers, cooks, bartenders, fishmongers, etc.) and may be exacerbated by contact irritants or allergens. Immediate sensitivity to fresh foods can be a factor. In children, thumb sucking may initiate the condition. Eczema or psoriasis may predispose to chronic paronychia, as may poor peripheral circulation and rarely pemphigus vulgaris. Microtrauma, including overzealous manicuring of the cuticle, is also important. The middle and index fingers of the right hand and the middle finger of the left hand are most commonly affected, but any finger may be involved. Inflammation with bolstering of the nail fold and loss of the cuticle opens a space between the nail fold and the nail plate, which commonly becomes colonized with yeast, especially *Candida* species, and a wide range of other microorganisms. Acute exacerbations due to bacterial infection may occur.

Successful treatment relies on protection of the affected fingers from water, irritants, allergens, and trauma, together with antiinflammatory treatment using moderately potent or potent *topical corticosteroids*. *Tacrolimus* 0.1% ointment applied twice daily may also be effective. Swabs for yeast and bacteria should be taken, *anticandidal preparations* can be useful, and antibiotic preparations may also be needed. Treatment should be continued until the inflammation has subsided and the cuticle reformed and reattached to the nail plate (3 months or more). For repeated acute episodes, *intralesional or systemic corticosteroids plus systemic antibiotics* for a week may be useful. In cases where conservative management fails, surgery or *low-dose superficial radiotherapy* has been tried. For cases due to retronychia simple avulsion of the nail plate is normally curative, but conservative treatment using taping can be tried.

Drug-induced pseudopyogenic granulomatous paronychia responds to daily topical 2% *mupirocin* with *clobetasol propionate* ointment. Additionally, for patients on EGF or mTOR inhibitors oral *doxycycline* 100 mg twice daily or dose reduction may be useful.

Specific Investigations

- Skin swabs
- Open patch tests against fresh foods

Anaerobic paronychia

Whitehead SM, Eykyn SJ, Phillips I. Br J Surg 1981; 68: 420–2.

Swabs were taken from 116 acute paronychias. Anaerobes or mixed aerobes and anaerobes were isolated in 30%. Of 81 paronychias with aerobic organisms only, *S. aureus* was isolated in 69%.

Clinical and cytologic features of antibiotic-resistant acute paronychia

Durdu M, Ruocco V. J Am Acad Dermatol 2014; 70: 120–6.

Antibiotic-resistant paronychia may be infectious or noninfectious. Cytologic examination may be useful diagnostically and may prevent unnecessary use of antibiotics and surgical drainage procedures.

Refractory purulent paronychia in a young girl. Pediatric dermatology photoquiz. Diagnosis paronychial cutaneous leishmaniasis

Topal I, Duman H, Baz V, Gungor S, Kocaturk E, Ozekinci S. Pediatr Dermatol 2016; 33: 93–4.

Case report and successful treatment with complete resolution using intralesional meglumine antimonite once a week for 5 weeks.

Chronic paronychia. Short review of 590 cases

Frain-Bell W. Trans St John's Hosp Dermatol Soc 1957; 38: 29–35.

On culture, *Candida albicans* was grown in 70% and bacteria, including *S. aureus*, in 10%.

An excellent overview.

Role of foods in the pathogenesis of chronic paronychia

Tosti A, Guerra L, Morelli R, Bardazzi F, Fanti PA. J Am Acad Dermatol 1992; 27: 706–10.

Nine of 20 food handlers with chronic paronychia had positive reactions to 20-minute open patch tests with suspected fresh foods, including wheat flour, egg, chicory, and tomatoes.

First-Line Therapies

Acute

• Amoxicillin with clavulanic acid	E
• Surgical drainage	E

Chronic

• Topical corticosteroid preparations	B
• Topical tacrolimus 0.1% ointment	B
• Topical clotrimazole drops	E
• Topical clindamycin solution	E

Due to retronychia

• Avulsion of nail plate	E
--------------------------	----------

Drug-induced periungual granuloma

• Mupirocin and clobetasol propionate	E
---------------------------------------	----------

EGF- or mTOR inhibitor–induced paronychia

• Doxycycline	E
• Dose reduction	E

Paronychia: a mixed infection, microbiology and management

Brook I. J Hand Surg [Br] 1993; 18: 358–9.

Culture from 61 patients with paronychia showed a mixture of both aerobic and anaerobic bacteria in 49%. The combination of amoxicillin with clavulanic acid is suggested as first-line treatment for acute bacterial paronychia, together with appropriate surgical drainage.

Nail surgery and traumatic abnormalities

Thomas L, Zook E, Rosio T, Dawber R, Haneke E, Baran R. In: Baran R, de Berker D, Holzberg M, Thomas L, eds. Baran and Dawber's Diseases of the Nails and Their Management, 4th edn. Wiley-Blackwell, 2012; 623–4.

For acute paronychia, under local anesthesia the proximal third of the nail plate is removed and a wick laid under the proximal nail fold.

Topical steroids versus systemic antifungals in the treatment of chronic paronychia: an open, randomized double-blind and double dummy study

Tosti A, Piraccini BM, Ghetti E. J Am Acad Dermatol 2002; 47: 73–6.

An open, randomized, double-blind trial of oral itraconazole, oral terbinafine, and topical methylprednisolone aceponate. Patients were treated for 3 weeks and observed for a further 6 weeks. Of 48 nails treated with methylprednisolone aceponate, 41 (85%) were improved or cured at the end of the study, compared with only 30 of 57 (53%) with itraconazole and 29 of 64 (45%) with terbinafine.

Efficacy and safety of tacrolimus ointment 0.1% vs. betamethasone 17-valerate 0.1% in the treatment of chronic paronychia: an unblinded randomized study

Rigopoulos D, Gregoriou S, Belyayeva E, Larios G, Kontochristopoulos G and Katsambas A. Br J Dermatol 2009; 160: 858–60.

This open study showed that both topical tacrolimus 0.1% and betamethasone 17-valerate 0.1% ointments applied twice daily to the affected perionychium gave statistically significantly better cure or improved rates compared with placebo. Also, in this study, tacrolimus 0.1% ointment appeared to be more effective than betamethasone 17-valerate 0.1% ointment.

The management of superficial candidiasis

Hay RJ. J Am Acad Dermatol 1999; 40: S35–42.

The central role of *Candida* in chronic paronychia is debatable, and other factors such as irritant or allergic dermatitis may play a role. Therefore, in addition to polyenes or imidazoles, concomitant use of a topical corticosteroid is a logical approach.

Diseases of the nails in infants and children: paronychia

Silverman RA. In: Callen JP, Dahl MV, Golitz LE, Schachner LA and Stegman SJ, eds. Advances in Dermatology. Vol. 5. Chicago: Mosby Year Book, 1990; 164–5.

Clotrimazole drops several times a day should inhibit fungal growth. Topical clindamycin solution applied to the fingers several times daily kills bacteria, has a bitter taste to discourage finger sucking, and has an alcohol–propylene glycol vehicle that dries out residual moisture. Side effects from oral absorption of these medications have not been reported.

Retronychia – clinical and pathophysiological aspects

Ventura F, Correia O, Duarte A, Barros A, Haneke E. JEADV 2016; 30: 16–9.

Review of 20 cases of retronychia. Avulsion of the nail confirms the diagnosis and is the curative treatment.

Paronychia associated with antiretroviral therapy

Tosti A, Piraccini BM, D’Antuono A, Marzaduri S. and Bettoli V. Br J Dermatol 1999; 140: 1165–8.

Six cases of periungual pseudopyogenic granuloma induced by indinavir, lamivudine, and zidovudine responded to daily applications of clobetasol propionate and mupirocin.

Doxycycline for the treatment of paronychia induced by the epidermal growth factor receptor inhibitor cetuximab

Suh K-Y, Kindler HL, Medenica M, and Lacouture M. Br J Dermatol 2006; 154: 191–2.

During treatment with cetuximab a patient developed painful paronychia, refractory to topical mupirocin and cephalexin but improved after treatment with doxycycline 100 mg twice daily.

Paronychia and pyogenic granuloma induced by new anticancer mTOR inhibitors

Sibaud V, Dalenc F, Mourey L and Chevereau C, et al. Acta Derm Venereol 2011; 91: 584–5.

Seven patients treated with mTOR inhibitors presenting with chronic paronychia were treated variously with topical steroids, silver nitrate, topical antibiotics, and oral doxycycline and pristinamycin; three patients required dose reduction.

Second-Line Therapies

Chronic

• Nystatin ointment	E
• Intralesional or systemic corticosteroids and antibiotics	E

Treatment of chronic paronychia

Vickers HR. Br Med J 1979; 2: 1588.

A nystatin-containing ointment should be worked into the affected nail fold every time the patient is going to get the hands wet, for at least 6 weeks.

Fungal (onychomycosis) and other infections involving the nail apparatus

Hay RJ, Baran R. In: Baran R, deBerker D, Holzberg M, Thomas L, eds. Baran and Dawber's Diseases of the Nails and Their Management, 4th edn. Hoboken, NJ: Wiley-Blackwell, 2012; 239.

For frequent acute exacerbations of chronic paronychia, intralesional or systemic corticosteroids plus either erythromycin 1 g daily or tetracycline 1 g daily for a week is recommended.

Third-Line Therapies

Acute

• Leeches

E

Chronic

• Eponychial marsupialization	C
• Excision of nail fold	E
• Superficial low-dose radiotherapy	E

Thumb paronychia treated with leeches

Graham CE. Med J Aust 1992; 156: 512.

Acute paronychia successfully treated with leeches while trekking in Tasmania.

Eponychial marsupialization and nail removal for surgical treatment of chronic paronychia

Bednar MS, Lane LB. J Hand Surg [Am] 1991; 16: 314–7.

Twenty-eight fingers with chronic paronychia were treated with marsupialization of the dorsal roof of the proximal nail fold plus complete or partial removal of the nail in those patients with associated nail abnormality. Postoperative treatment was with hydrogen peroxide soaks and oral antibiotics for 5 to 14 days. Twenty-seven of 28 fingers were cured.

Surgical treatment of recalcitrant chronic paronychia of the fingers

Baran R, Bureau H. J Dermatol Surg Oncol 1981; 7: 106–7.

Description of the technique of simple excision of the affected nail fold without the need for marsupialization.

How we treat paronychia

Fliegelman MT, Lafayette GO. Postgrad Med 1970; 48: 267–8.

For recalcitrant cases of chronic paronychia, triamcinolone can be injected into the affected nail fold. For the most severe cases, a course of low-dose superficial radiotherapy may be given.

Periungual Bowen disease mimicking chronic paronychia and diagnosed by dermoscopy

Giacomel J, Lallas A, Zalaudek I, Argenziano G. J Am Acad Dermatol 2014; 71: e65–7.

Parvovirus infection

Andrea L. Zaenglein, and Joanne E. Smucker

Infection with human parvovirus B19 (HPB19) causes a variety of well-described exanthems and can result in a spectrum of systemic illness. Erythema infectiosum, also known as *fifth disease* according to the original classification of childhood exanthems, is the classic and most common eruption associated with HPB19 infection. Outbreaks

occur in the winter and spring and affect school-aged children between 5 and 15 years of age. The infection is transmitted via respiratory droplets. After a short variable prodrome of fever, malaise, diarrhea, and pharyngitis, the classic features of the exanthem appear. Bright pink macular erythema of the cheeks (“slapped cheek sign”) together with nasal bridge and circumoral pallor precedes an evanescent macular, reticulated, or “lacelike” rash over the trunk and proximal limbs. The rash may last for up to 4 weeks and subsequently may recur after exposure to sun, warm temperature, and intense physical activity (see figure). Purpuric eruptions, most commonly the papular purpuric gloves-and-socks syndrome (PPGSS), are also reported in association with HPB19. Arthropathy is another common finding, particularly in older patients affected with HPB19. Other systemic manifestations of HPB19 infection include idiopathic thrombocytopenic purpura, hemophagocytic syndrome, lymphadenitis, meningitis and encephalitis, hepatitis, myocarditis, nephritis, and vasculitis. In patients with a predisposing hematologic condition, infection with HPB19 may cause a transient aplastic crisis. Chronic and secondary infections have been encountered in immunosuppressed patients and rarely in immunocompetent patients. Primary infection during pregnancy may place the fetus at risk for severe anemia, thrombocytopenia, hydrops fetalis, neurologic sequelae, and intrauterine fetal demise.

Management Strategy

Erythema infectiosum is typically a self-resolving exanthem. In the majority of cases, *supportive care and reassurance* are all that is required. The rash of erythema infectiosum is immune complex mediated so patients are assumed to be no longer infectious by the time that it appears. HPB19 IgG is detectable in the blood once the eruption occurs. Once a clinical diagnosis has been made, parents can be reassured and advised on simple supportive measures such as antipyretics, fluids, and simple emollients for the rash. The condition is self-resolving in the majority of immunocompetent patients.

The clinician should be aware of a variety of other less common cutaneous presentations of HPB19 infection, including both petechial and nonpetechial eruptions. The most common is the PPGSS. This consists of pruritic to painful edema, erythema, and petechiae of the

hands and feet with a classic sharp demarcation at the wrist and ankles. This eruption may be seen together with the “slapped cheek” sign. An enanthem may occur with palatal, pharyngeal, labial, and lingual erythema, petechiae, and ulcerations. A diffuse papular exanthem, fever, and other nonspecific viral symptoms may accompany the eruption. PPGSS is seen more often in the spring and summer and typically occurs in adolescents and young adults. Unlike in erythema infectiosum, patients with PPGSS have been reported to be viremic while the rash is present and are thus contagious. The eruption typically resolves within 1 to 2 weeks with simple supportive measures. More generalized petechial eruptions have been reported either primarily or after classic erythema infectiosum. The acropetechial syndrome involves the perioral skin in addition to the hand and foot involvement classically seen in PPGSS. A petechial eruption in a bathing trunk distribution has also been described. Parvovirus should be suspected with all petechial rashes whose origin is undetermined. Asymmetric periflexural exanthema (unilateral lateral thoracic syndrome) and papular acrodermatitis of childhood (Gianotti–Crosti syndrome) have been described after HPB19 infection. HPB19 is also in the differential diagnosis of the “blueberry muffin” baby. Other possible associations with cutaneous manifestations include erythema nodosum, erythema multiforme, livedo reticularis, vasculitis, Sweet syndrome, and Behçet disease.

HPVB19 infection may cause a symmetric arthropathy in many adults, most commonly women, and up to 10% of children. It is similar to rheumatoid arthritis involving the wrists, ankles, knees, and metacarpophalangeal and proximal interphalangeal joints. Arthropathy may accompany the cutaneous eruption but frequently follows it. The arthritis is usually self-limited in both adults and children, requiring only *nonsteroidal antiinflammatory drugs (NSAIDs)* for symptomatic relief. Occasionally the arthritis may lead a more chronic course, and it has been suggested that infection with HPB19 may be a trigger for autoimmune arthritis and connective tissue disease.

HPB19 is extremely tropic for proerythroblasts, granulocytes, and platelets. It binds to globoside on the erythrocyte precursor cell membrane, where it is endocytosed, replicates, and causes cellular apoptosis. In predisposed individuals with either an underlying disorder of hemolysis, decreased erythrocyte production, or active bleeding, HPB19 infection can cause a transient aplastic crisis. This

acute anemia may be self-limited and asymptomatic, but *transfusion* may be indicated if severe. In addition to anemia, there may be moderate neutropenia and thrombocytopenia. Potentially fatal marrow necrosis rarely occurs in very young children. Severe cases of transient aplastic crisis not responding to transfusion may require intravenous immunoglobulin (IVIG) and even *bone marrow transplantation*. Chronic HPB19 infection in immunosuppressed patients can result in pure red blood cell aplasia, a form of chronic anemia that results from the inability to create neutralizing antibodies to the virus. This is treated with IVIG, which is often curative. Of interest, parvovirus B19 can contaminate blood products, including bone marrow, and may have the ability to transmit infection through this means. Children who are already anemic due to other causes, such as malaria, malnutrition, or parasites, can become profoundly anemic with HPB19 infection.

Patients with AIDS and chronic anemia secondary to HPB19 infection, who are treated with highly active antiretroviral therapy (HAART), with recovery of CD4 counts, have had resolution of their anemia with documented seroconversion from IgM to IgG antiparvovirus antibodies. Other AIDS patients started on HAART experienced an immune reconstitution syndrome. With the development of renewed immunity, AIDS patients can experience overwhelming systemic involvement of parvovirus, resulting in encephalitis, severe anemia, or other severe sequelae.

Fetal infection with parvovirus B19 may result in mild to severe anemia, thrombocytopenia, high-output congestive heart failure, nonimmune hydrops fetalis, and fetal death. Fetal stroke and other neurologic sequelae have been reported. Fetal infection occurs usually during the first 20 weeks of pregnancy, although third trimester hydrops-related and spontaneous nonhydrops-related fetal demise has been reported. One third or more of women of childbearing age do not have IgG antibodies to HPB19 and are susceptible to primary infection. Vertical transmission occurs in 33% of women, and fetal complications occur in 3% of infected women. Vertical transmission is higher during epidemics. Testing maternal serum for IgM and IgG titers and/or HPB19 DNA with polymerase chain reaction (PCR) analysis should be performed in pregnant women who develop symptoms of HPB19 infection or are in contact with children with a known parvovirus infection. If they have serologic evidence of primary infection, serial fetal ultrasonography should be performed

to evaluate for signs of fetal anemia and hydrops fetalis. If hydrops fetalis is present, cordocentesis to confirm the presence of anemia and *intrauterine transfusion* should be strongly considered. Treatment with transfusion is lifesaving in appropriately selected patients and results in favorable long-term neurodevelopmental outcomes. If the pregnancy is near or at term, delivery should be considered. Pregnant women with normal immunity and IgG antibodies to HPB19, or those with a remote history of infection, can be reassured that exposure to HPB19 during pregnancy will not have adverse outcomes on their pregnancy.

Rarely additional systemic involvement, including renal, neurologic, hepatic, respiratory, ocular, and endocrine, has been reported during acute infection with HPB19. Viral myocarditis can also occur, resulting in significant morbidity and mortality, including ventricular dysfunction and heart failure. HPB19 infection can mimic various connective tissue disorders, in particular systemic lupus erythematosus, dermatomyositis, and vasculitis. Infection with HPB19 has also been shown to play a role in the development of a multitude of chronic conditions, including, but not limited to, other connective tissue disease, hepatitis, nephritis, neurologic disease, and malignancy. However, a causal relationship has not been established.

Specific Investigations

- Hematology (complete blood count)
- Serology

Although most parvovirus infections are diagnosed clinically, there may be instances such as atypical presentations with systemic concerns or new-onset arthropathy of unknown cause where diagnostic testing may be warranted. Serologic testing includes analysis for IgM and IgG antibodies using enzyme-linked immunoassay (ELISA), radioimmunoassay, or immunofluorescence. IgM to HPB19 indicates recent infection. Sensitivity and specificity vary greatly based on the technical skill of the test performer. HPB19-specific IgG antibodies indicate past exposure and may be positive in over half the adult population.

A typical clinical appearance together with supportive serology is sufficient to establish the diagnosis in the majority of cases. In at-risk patients or those who have symptoms of anemia, a complete blood

count will establish whether there is any significant level of anemia requiring transfusion.

It is possible to detect parvovirus DNA in both the blood and lesional skin. PCR techniques are considered extremely sensitive and may be useful in the following clinical scenarios: patients with an atypical presentation of HPB19 infection, where the clinical suspicion of infection is high and antibody studies are negative, and in immunocompromised patients who cannot mount an appropriate immunoglobulin response. In addition, a window period exists during the first 7 days after exposure when IgG and IgM are negative, and a second period exists where IgM has become undetectable. PCR may also be helpful during these periods.

Parvovirus B19

Young NS, Brown KE. N Engl J Med 2004; 350: 586–97.

A comprehensive review of HPB19 infection and its manifestations is detailed.

The cutaneous manifestations of human parvovirus B19 infection

Magro CM, Dawood MR, Crowson N. Hum Pathol 2000; 31: 488–97.

This is a description of the cutaneous manifestations in a series of 14 patients who were shown to have antecedent HPB19 infection with positive serology and/or B19 genome in skin samples.

Human parvovirus B19 specific IgG, IgA, and IgM antibodies and DNA in serum specimens from persons with erythema infectiosum

Erdman DD, Usher MJ, Tsou C, Caul EO, Gary GW, Kajigaya S, et al. J Med Virol 1991; 35: 110–5.

A study looking at the efficacy of testing for parvovirus infection with antigen-specific antibodies versus PCR.

First-Line Therapies

• Reassurance	E
• Antipyretics (e.g., acetaminophen [paracetamol], ibuprofen)	E

Human parvoviruses

Schneider E. In: Long S, Pickering L, Prober C, eds. Principles and Practices of Pediatric Infectious Diseases, 4th edn. Philadelphia: Elsevier, 2012; 1087–91.

Most children require no specific therapy. Simple supportive therapies may be used. No antiviral drug or vaccine is available. Viral vaccination is under development.

Second-Line Therapies

• NSAIDs	E
• Systemic corticosteroids	E
• Blood transfusion	C

Human parvovirus infection: rheumatic manifestations, angioedema, C1 esterase inhibitor deficiency, ANA positivity and possible onset of systemic lupus erythematosus

Fawaz-Estrup F. J Rheumatol 1996; 23: 1180–5.

A series of nine adult patients with serologic evidence of acute or recent HPB19 infection and polyarthralgia/polyarthritis. All patients responded to NSAIDs, although one patient also required pulsed intravenous methylprednisolone for a lupuslike illness.

In older children and adults the arthralgia/arthritis may be severe enough to warrant treatment with an NSAID. In the majority of cases the joint symptoms settle within a few days or weeks.

Parvoviruses and bone marrow failure

Brown KE, Young NS. Stem Cells 1996; 14: 151–63.

In patients with underlying hemolytic disorders, infection with HPB19 is the primary cause of a transient aplastic crisis, which may require transfusion. In immunocompromised patients, persistent infection may manifest as pure red cell aplasia and chronic anemia.

Third-Line Therapies

• Immunoglobulin infusion	C
• Bone marrow/stem cell transplantation	D
• Intrauterine transfusion	C
• HAART	E

Persistent B19 parvovirus infection in patients infected with human immunodeficiency virus type 1 (HIV-1): a treatable cause of anaemia in AIDS

Frickhofen N, Abkowitz J, Safford M, Berry JM, Antunez-de-Mayolo J, Astrow A, et al. Ann Intern Med 1990; 113: 926–33.

This is a series of seven patients who were HIV positive with persistent HPB19 infection and anemia. Six patients were treated with IVIG and showed rapid reduction in serum virus concentrations and subsequent resolution of their anemia. Two patients relapsed but again responded to further immunoglobulin.

Intravenous immunoglobulin therapy for pure red cell aplasia related to human parvovirus B19 infection: a retrospective study of 10 patients and review of the literature

Crabot Y, Terrier B, Rozenber F, Pestre V, Legendre C, Hermine O, et al. Clin Infect Dis 2013; 56: 968–77.

A review of efficacy of IVIG for therapy of pure red cell aplasia (PRCA) related to HPV-B19 infection. IVIG was found to be effective for short-term use in immunocompromised patients with HPV-B19 PRCA.

Intravenous immunoglobulin treatment of four patients with juvenile polyarticular arthritis associated with persistent parvovirus B19 infection and antiphospholipid antibodies

Lehmann HW, Plentz A, Von Landenberg P, Müller-Godeffroy E, Modrow S. Arthritis Res Ther 2004; 6: R1–6.

A small series of four children with oligoarthritis and polyarthritis and chronic HPB19 infection treated with IVIG (in addition to other therapies) with variable improvement in symptoms and quality-of-life measurements. Dosing for the IVIG was 0.4 g/kg/day for 5 successive days. Two cycles were given 1 month apart.

Mononeuropathy multiplex associated with acute parvovirus B19 infection: characteristics, treatment and outcome

Lenglet T, Haroche J, Schnuriger A, Maisonobe T, Viala K, Michel Y, et al. J Neurol 2011; 258: 1321–6.

The course of three patients with HPB19 virus-positive neuropathy is described. Treatment with IVIG resulted in good but incomplete improvement in symptoms.

Stem cell transplantation in 6 children with parvovirus B19-induced severe aplastic anaemia or myelodysplastic syndrome

Urban C, Lackner H, Müller E, Benesch M, Strenger V, Sovinz P, et al. Klin Padiatr 2011; 223: 332–4.

This is a small series of children infected with HPB19 with resultant refractory bone marrow failure treated with stem cell transplantation.

Parvovirus associated fulminant hepatic failure and aplastic anemia treated successfully with liver and bone marrow transplantation

Bathla L, Grant W, Mercer D, Vargas L, Gebhart C, Langnas A. Am J Transplant 2014; 14: 2645–50.

This is a report of two case reports of children with hepatic failure secondary to HPV-B19 complicated with aplastic anemia who underwent liver transplant and bone marrow transplantation with excellent outcomes.

Fetal morbidity and mortality after acute parvovirus B19 infection in pregnancy: prospective evaluation of 1018 cases

Enders M, Weidner A, Zoellner I, Searle K, Enders G. Prenat Diagn 2004; 24: 513–8.

Survival in fetuses with severe hydrops fetalis after intrauterine transfusion was 84.6% (11/13). All fetuses with severe hydrops who were not transfused died.

Parvovirus B19 in pregnancy: prenatal diagnosis and

management of fetal complications

Dijkmans AC, de Jong EP, Dijkmans BA, Lopriore E, Vossen A, Walther FJ. Curr Opin Obstet Gynecol 2012; 24: 95–101.

This is a review of the current approach to women exposed to HPB19 in pregnancy.

Resolution of chronic parvovirus B19 induced anemia, by use of highly active antiretroviral therapy in a patient with acquired immunodeficiency syndrome

Ware M. Clin Infect Dis 2001; 32: E122–3.

A case of an AIDS patient with transfusion-dependent anemia caused by HPB19 that resolved with HAART therapy is reported.

Pediculosis

Hee J. Kim, and Jacob O. Levitt

Lice are wingless, dorsoventrally flattened, blood-sucking insects that are obligate ectoparasites of birds and mammals. Pediculosis denotes an infestation by *Pediculus capitis* (head louse), *Pediculus humanus* (body or clothing louse), or *Phthirus pubis* (pubic or crab louse). The bites of lice are painless and can rarely be detected. The clinical signs and symptoms are the result of the host's reaction to the saliva, which has vasodilatory and anticoagulation properties. Saliva

is injected into the dermis by the louse at the time of feeding. Depending on immune sensitivity and previous exposure, red macules or papules develop hours to days after feeding. Pruritus is the most common symptom of any type of pediculosis. If left untreated, superinfection of excoriations may lead to impetiginous crusts and regional lymphadenopathy.

Pediculosis Capitis

Management Strategy

In the United States, an estimated 6 to 12 million people are infested with head lice every year. Children 3 to 12 years old and their parents are most commonly affected. Identification of live lice is the gold standard of diagnosis; however, finding nits alone in a patient who has not been treated warrants treatment. One study showed that around 20% of patients found to have nits alone eventually develop live lice. Nits are easier to spot, especially at the nape of the neck and behind the ears. Hatched nits are white; unhatched nits are brown. Detection combing of wet hair with a fine-toothed nit comb allows efficient recovery of lice and nits for diagnosis.

Management must take into consideration key elements of the head louse life cycle. It takes 4 days to develop a nervous system in the egg, 12 days at most to hatch, and 7 days after hatching for the nymph to lay eggs. Contrary to the direction of most non-ovicidal pediculicides, one retreatment in 7 days will not kill all viable nits. As such, therapies that do not kill eggs require three weekly treatments. Pediculicides that are ovicidal require two treatments separated by 1 week. Agents that act on the louse nervous system will not affect ova that are less than 4 days old. Lice are sensitive to dehydration but can live off the host for up to 55 hours. Transmission is mainly by direct head-to-head contact. Indirect spread through fomites is also possible. Until definitive safety data are available, the occasional patient under 2 years old should be treated with *mechanical methods*.

Laundryable items (worn clothing and used bedding, towels, scarves, and hats) should be *placed in a dryer at 60°C* (i.e., on high) for at least 10 minutes. Brushes, combs, and hair ornaments can be placed in hot (60°C or more) water for 10 minutes. Nonlaundryable items (i.e., certain stuffed animals) should be placed in a bag for 3 days (not 15 days, as eggs laid off a host are unlikely to hatch near a host to

obtain their first blood meal). Clothes, furniture, and rugs should be vacuumed. Fumigation of the home is discouraged.

Contacts of index cases, including classmates and family members, *should be screened*. Empiric therapy for close household contacts, particularly if they share a bed, is justifiable. Those likely to have had head-to-head contact with the index case in the prior 4 to 6 weeks should be identified and screened. Children should not be excluded from school for head lice, as the infestation often has been ongoing for months before its detection. Hair grows 1 cm per month, and lice lay eggs close to the scalp where it is moist and warm. Nits detected 2 cm from the scalp represent a 2-month-old infestation. Requiring therapy within a week of the detected infestation is reasonable.

Considerations guiding therapy include safety and efficacy. The efficacy of chemical modalities depends on regional resistance patterns of lice. Because of widespread resistance to permethrin and lindane, *malathion* formulated in isopropyl alcohol with terpineol remains the most effective therapy due to its ovicidal and pediculicidal properties. *Topical ivermectin* lotion and *spinosad topical suspension* have proven to be effective alternatives. A less reliable topical option is *benzyl alcohol lotion*. Alternatives that do not act on the louse nervous system are *mechanical methods* such as louse occlusion, cuticle disruption, and physical removal. Barring shaving the head, these modalities are often unreliable and result in recurrent infestation between treatments and continued infectiveness.

Specific Investigations

- Examination for nits and lice via detection combing
- Dermoscopy

Plastic detection comb better than visual screening for diagnosis of head louse infestation

Balcioglu C, Burgess IF, Limoncu ME, Sahin MT, Ozbel Y, Bilac C, et al. *Epidemiol Infect* 2008; 136: 1425–31.

Detection combing is 3.84 times more effective than visual inspection for finding live head lice.

Dermoscopy for diagnosis and treatment monitoring of pediculosis capitis

Di Stefani A, Hofmann-Wellenhof R, Zalaudek I. J Am Acad Dermatol 2006; 54: 909–11.

A handheld noncontact dermatoscope can be used to differentiate eggs containing nymphs, empty cases of hatched lice, and pseudo-nits. Treatment success can also be monitored using the dermatoscope.

First-Line Therapies

• Malathion 0.5% lotion	A
• Benzyl alcohol 5% lotion	A
• Ivermectin 0.5% lotion	A
• Spinosad 0.9% topical suspension	A
• Permethrin 1% cream rinse	A

Therapy for head lice based on life cycle, resistance, and safety considerations

Lebwohl M, Clark L, Levitt J. Pediatrics 2007; 119: 965–74.

This article highlights the importance of designing treatment schedules in accordance with the head lice life cycle. Malathion 0.5% in isopropyl alcohol 78% with terpineol 12% is a safe, resistance-breaking formulation approved by the Food and Drug Administration (FDA) as a first-line treatment for head lice. Two treatments 1 week apart correlate with the head lice life cycle. There is no evidence to suggest that the second application, 1 week later, is unsafe. A single treatment cures 70% to 80% of cases.

Knockdown resistance allele frequencies in North American head louse (*Anoplura: Pediculidae*) populations

Yoon KS, Previte DJ, Hodgdon HE, Poole BC, Kwon DH, El-Ghar GE, et al. J Med Entomol 2014; 51: 450–7.

A high frequency of kdr-type T917I mutation in head lice is

reported: 84.4% in the United States from 1999 to 2009, increased to 99.6% from 2007 to 2009. This is responsible for complete insensitivity of the louse voltage-gated sodium channel to permethrin.

Effectiveness of Ovide against malathion-resistant head lice

Downs AM, Narayan S, Stafford KA, Coles GC. Arch Dermatol 2005; 141: 1318.

In this in vitro study, Ovide (containing malathion, terpineol, and isopropyl alcohol) killed 100% of British head lice resistant to malathion after a 60-minute exposure. Terpineol and malathion appear to be effective in overcoming resistance.

Efficacy of a reduced application time of Ovide lotion (0.5% malathion) compared with Nix crème rinse (1% permethrin) for the treatment of head lice

Meinking TL, Vicaria M, Eyerdam DH, Villar ME, Reyna S, Suarez G. Pediatr Dermatol 2004; 21: 670–4.

Reduced application time (20 minutes) of Ovide cured 98% (40 of 41) of subjects on day 15 compared to Nix (10 minutes), which cured 55% (12 of 22); 19.5% of Ovide patients and 40.9% of Nix patients required a second treatment on day 8. Reinfestation rates were 0% for Ovide and 23% for Nix.

Permethrin 1% obtained approval with well-done studies decades ago; however, resistance has caused permethrin cure rates to decline dramatically.

The clinical trials supporting benzyl alcohol lotion 5% (Ulesfia): a safe and effective topical treatment for head lice (pediculosis humanus capitis)

Meinking TL, Villar ME, Vicaria M, Eyerdam DH, Paquet D, Mertz-Rivera K, et al. Pediatr Dermatol 2010; 27: 19–24.

Benzyl alcohol lotion 5% was studied in 695 subjects. Two multicenter, randomized, double-blind, placebo-controlled trials showed a cure rate of ~67% in 126 subjects.

Benzyl alcohol stuns breathing spiracles open, allowing the vehicle to asphyxiate the lice.

Assessment of topical versus oral ivermectin as a treatment for head lice

Ahmad HM, Abdel-Azim ES, Abdel-Aziz RT. Dermatol Ther 2014; 27: 307–10.

This study compared the efficacy of a single topical application of 1% ivermectin solution to a single dose of oral (200 µg/kg per dose) ivermectin. After 1 week, patients who received topical ivermectin had a significantly higher cure rate of 88%. No recurrence of infestation was observed after a 4-week end point.

Topical 0.5% ivermectin lotion for treatment of head lice

Pariser DM, Meinking TL, Bell M, Ryan WG. N Engl J Med 2012; 367: 1687–93.

Two placebo-controlled trials assessing the efficacy of a single 10-minute application of ivermectin lotion without nit combing were conducted in 765 individuals aged 6 months and older.

Approximately 79% of subjects remained louse free for 15 days after a single treatment.

Efficacy and safety of spinosad and permethrin creme rinses for pediculosis capitis (head lice)

Stough D, Shellabarger S, Quiring J, Gabrielsen AA Jr. Pediatrics 2009; 124: 389–95.

Two investigator-blinded studies compared 0.9% spinosad without nit combing to 1% permethrin with combing in 1038 subjects aged ≥6 months. The efficacy of spinosad (~86%) was statistically superior to permethrin (~44%). Spinosad did not require a combing step, and most patients required one rather than two applications.

Spinosad was more effective than permethrin, which is currently recommended first-line treatment by the American Academy of Pediatrics.

Second-Line Therapies

Topical occlusion therapy (suffocants)

• Dimeticone 4% to 100% lotion	A
• Isopropyl myristate 50% in 50% ST-cyclomethicone	A
• Cetaphil liquid cleanser	B
• 1,2-Octanediol 1% spray	A
• Tocopheryl acetate 20% spray	A

Chemical agents

• Topical crotamiton 10%	B
• Carbaryl 0.5% lotion	E
• Melaleuca oil and lavender oil	A

Nit picking

• Bug busting	A
• Professional nit picking services	E

Single application of 4% dimeticone liquid gel versus two applications of 1% permethrin crème rinse for treatment of head louse infestation: a randomized controlled trial

Burgess IF, Brunton ER, Burgess NA. BMC Dermatol 2013; 13: 5.

In this single-center, parallel-group, randomized, controlled, open-label trial, one application of 4% dimeticone liquid gel for 15 minutes had a significantly higher success rate at 77.1% than that of 1% permethrin.

Dimeticone (also known as dimethicone) penetrates the respiratory spiracles of lice and interrupts oxygen supply, leading to organism death.

Randomised, controlled, parallel group clinical trials to evaluate the efficacy of isopropyl myristate/cyclomethicone solution against head lice

Burgess IF, Lee PN, Brown CM. Pharmaceut J 2008; 280: 371–5.

In this randomized, controlled, assessor-blind, parallel-group trial involving 168 subjects with head louse infestation, patients treated with 10-minute single application of isopropyl myristate/cyclomethicone (IPM/C) solution had a significantly higher cure rate of 82% on day 14 compared to those treated with permethrin

1%. IPM/C was easier to apply and less odorous.

A simple treatment for head lice: dry-on, suffocation-based pediculicide

Pearlman DL. Pediatrics 2004; 114: e275–9.

Cetaphil cleanser is applied to the hair and dried with a hair dryer, followed by nit combing. This is repeated three times at intervals of a week apart. A total of 133 patients were studied; 96% efficacy is claimed.

1,2-Octanediol, a novel surfactant, for treating head louse infestation: identification of activity, formulation, and randomised, controlled trials

Burgess IF, Lee PN, Kay K, Jones R, Brunton ER. PLoS One 2012; 7: e35419.

In this observer-blinded study of 520 subjects, the cure rate of an application of 1,2-octanediol 5% lotion was 70.9% for 2 to 2.5 hours and 87.9% for 8 hours/overnight, both more effective than 0.5% malathion liquid.

Octanediol eliminates lice by disrupting the insect's cuticular lipid and causing dehydration.

Tocopheryl acetate 20% spray for elimination of head louse infestation: a randomised controlled trial comparing with 1% permethrin creme rinse

Burgess IF, Burgess NA, Brunton ER. BMC Pharmacol Toxicol 2013; 14: 43.

Two treatments, 7 days apart, with tocopheryl acetate 20% spray (applied to dry hair for 20 minutes and then washed), had a cure rate of 73.9% (17/23) compared to 22.7% (5/22) with permethrin 1% crème rinse.

Tocopheryl acetate immobilizes lice and inhibits eggs from hatching via physical mechanism of action.

A single application of crotamiton lotion in the treatment of patients with pediculosis capitis

Karaci I, Yawalkar SJ. Int J Dermatol 1982; 21: 611–3.

Forty-seven of 49 subjects were cured with one application of crotamiton 10% lotion, and all were cured with a second application in 1 week.

The trial was open label and never independently validated.

A randomised, assessor blind, parallel group comparative efficacy trial of three products for the treatment of head lice in children—melaleuca oil and lavender oil, pyrethrins and piperonyl butoxide, and a “suffocation” product

Barker SC, Altman PM. BMC Dermatol 2010; 10: 6.

Cure rates were as follows: melaleuca (tea tree) oil and lavender oil (41/42; 98%); NeutraLice, a suffocation product (40/41; 98%); products containing pyrethrins and piperonyl butoxide (10/40; 25%).

Single blind, randomised, comparative study of the Bug Buster kit and over the counter pediculicide treatments against head lice in the United Kingdom

Hill N, Moor G, Cameron MM, Butlin A, Preston S, Williamson MS, et al. Br Med J 2005; 331: 384–7.

A cure rate of 57% (32/56) is reported for wet combing with conditioner in four sessions over 13 days.

Nit combing can be painful and time consuming but may be worthwhile for treatment of lice that are resistant to pharmacotherapy.

Third-Line Therapies

• Oral ivermectin	A
• Oral trimethoprim–sulfamethoxazole	B
• Oral levamisole	B
• Albendazole 2% suspension	E
• Desiccation	B
• Head shaving	E

Lindane toxicity: a comprehensive review of the medical

literature

Nolan K, Kamrath J, Levitt J. *Pediatr Dermatol* 2012; 29: 141–6.

Lindane has been associated with significant adverse reactions, including death, seizures, shortness of breath, and hematologic effects. Lindane has been banned in some U.S. states, including California and Michigan. It is no longer recommended for use in children younger than 10 years old, those weighing less than 50 kg, breastfeeding women, older adults, or people with compromised dermal barriers.

Given the significant toxicity associated with lindane and the availability of other safer treatments, lindane should be avoided.

Oral ivermectin versus malathion lotion for difficult-to-treat head lice

Chosidow O, Giraudeau B, Cottrell J, Izri A, Hofmann R, Mann SG, et al. *N Engl J Med* 2010; 362: 896–905.

This multicenter, cluster-randomized, double-blind, controlled trial conducted in 812 patients compared oral ivermectin (at a dose of 400 µg/kg body weight) with 0.5% malathion lotion, each given on days 1 and 8. Included were subjects who had live lice resistant to topical insecticide used 2 to 6 weeks prior to enrollment. In the intention-to-treat population, 95.2% of patients who received oral ivermectin were lice free on day 15, compared to 85.0% in those who used topical malathion. Oral ivermectin had superior efficacy without increase in side effects.

Safety studies of oral ivermectin in children are lacking.

Head lice infestation: single drug versus combination therapy with 1% permethrin and trimethoprim/sulfamethoxazole

Hipolito RB, Mallorca FG, Zuniga-Macaraig ZO, Apolinario PC, Wheeler-Sherman J. *Pediatrics* 2001; 107: E30.

Permethrin (1%) and trimethoprim (10 mg/kg/day divided BID)–sulfamethoxazole cured 38 of 40 (95%) of subjects by week 2. TMP–SMX monotherapy was 83% effective, and permethrin monotherapy was 79.5% effective.

Levamisole: a safe and economical weapon against pediculosis

Namazi MR. *Int J Dermatol* 2001; 40: 292–4.

Levamisole administered in a dose of 3.5 mg/kg for 10 days cured 67% (18/28) of children with head lice.

Treatment of pediculosis capitis with topical albendazole

Ayoub N, Maatouk I, Merhy M, Tomb R. J Dermatolog Treat 2012; 23: 78–80.

Four patients were successfully treated with topical albendazole 2% suspension.

Efficacy of the LouseBuster, a new medical device for treating head lice (Anoplura: Pediculidae)

Bush SE, Rock AN, Jones SL, Malenke JR, Clayton DH. J Med Entomol 2011; 48: 67–72.

LouseBuster is a medical device designed to kill head lice in all life stages by delivering heated air ($59 \pm 1.5^{\circ}\text{C}$) at two to three times greater airflow than a regular blow dryer. After 30-min treatment, mortality of lice and eggs was $\sim 94\%$ for both experienced and novice operators.

Pediculosis Corporis

Management Strategy

Because body lice live in the seams of clothing, treatment revolves around laundering of clothes and bedding in high heat ($>60^{\circ}\text{C}$) for at least 10 minutes. Infested mattresses should be abandoned for 3 weeks. Given that resistance patterns in head lice follow those of body lice, topical malathion, carbaryl, and permethrin are good first choices. Oral ivermectin is another alternative. All household contacts should be treated. Patients should be monitored for symptoms of louseborne illnesses, specifically epidemic typhus (*Rickettsia prowazekii*), relapsing fever (*Borrelia recurrentis*), and trench fever (*Bartonella quintana*).

First-Line Therapies

• Laundering of clothes and bedding	E
• Personal hygiene	E
• Malathion 0.5% lotion	E
• Permethrin 5% cream	E
• Oral ivermectin	B

Human lice and their management

Burgess IF. Adv Parasitol 1995; 36: 271–342.

A comprehensive review of human lice is provided. For body lice, laundering of clothing is stressed, and the use of pediculicides on the patient is questioned. In mass eradication, fomites can be dusted with malathion or permethrin.

Given the safety of topical therapy, two treatments applied for 8 to 12 hours 1 week apart outweigh the risk of stray lice on the host reestablishing infestation.

Oral ivermectin in the treatment of body lice

Foucault C, Ranque S, Badiaga S, Rovey C, Raoult D, Brouqui P. J Infect Dis 2006; 193: 474–6.

Administration of three doses of oral ivermectin 12 mg with a 7-day interval decreased the prevalence of subjects infested with body lice from 84.9% to 18.5% over a 14-day period. However, this effect was not sustained on day 45 after treatment. More studies need to be conducted to evaluate the efficacy of oral ivermectin.

Pediculosis Pubis

Management Strategy

Crab lice commonly affect pubic (mons and perianal), thigh, chest, and axillary hair, eyelashes, and rarely, scalp hair. Pediculicide should be applied to these areas to ensure eradication, and repeat application is recommended after 7 days. Eyelash infestation should

be treated separately (see later). Household contacts and sexual partners of the prior month should be treated. Fomites should be laundered as for head lice. Screening for other sexually transmitted diseases is advised.

First-Line Therapies

• Malathion 0.5% lotion	E
• Permethrin 1% crème rinse	B
• Permethrin 5% cream	E
• Pyrethrin 0.33% with piperonyl butoxide shampoo	E
• Oral ivermectin 200 µg/kilogram	E

Scabies and pediculosis pubis: an update of treatment regimens and general review

Leone PA. Clin Infect Dis 2007; 44 (Suppl 3): S153–9.

A comprehensive review of scabies and pediculosis pubis is provided. No significant treatment failure of pediculosis pubis has been reported since 1996. One study reported in vitro pubic lice resistance to pyrethrins; however, it was susceptible to permethrin 5% lotion. Lindane 1% shampoo is no longer recommended due to its toxicity.

Phthiriasis Palpebrarum

Management Strategy

Phthiriasis palpebrarum is an infestation of the eyelashes by crab lice. In children, the infested mother is often the source of infestation. Patients should be treated with application of either permethrin 1% lotion for at least 10 minutes or an occlusive ointment such as petroleum jelly twice a day for 10 days. Alternatives include yellow mercuric oxide, physostigmine 1% eye ointment, and mechanical removal. Treatment of household and sexual contacts and fomites is

warranted.

First-Line Therapies

• Petroleum jelly	E
• Permethrin 1% lotion	E
• Yellow mercuric oxide 1% ointment	B
• Mechanical lice and nit removal	E
• Physostigmine 0.25% or 1% ointment	E

Yellow mercuric oxide: a treatment of choice for phthiriasis palpebrarum

Ashkenazi I, Desatnik HR, Abraham FA. Br J Ophthalmol 1991; 75: 356–8.

Yellow mercuric oxide 1% ointment was applied four times daily for 14 days in 35 patients with phthiriasis palpebrarum. Complete eradication of lice and eggs was reported.

Pediculosis ciliaris

Chin GN, Denslow GT. J Pediatr Ophthalmol Strabismus 1978; 15: 173–5.

Physostigmine 1% ointment applied to eyelid margins twice a day for 14 days is reported. Other suggestions for therapy include (1) thick application of petroleum jelly twice a day for 8 days; (2) mechanical removal of lice and nits with forceps and cotton-tipped swabs followed by application of yellow oxide of mercury 1% to 2% ointment twice a day for 1 week; or (3) cryotherapy.

Second-Line Therapies

• Argon laser	E
• Cryotherapy	E
• Gamma benzene hexachloride	E
• Oral ivermectin	E

Oral ivermectin therapy for phthiriasis palpebrum

Burkhart CN, Burkhart CG. Arch Ophthalmol 2000; 118: 134–5.

A single case of oral ivermectin use in lash pediculosis.

Pemphigus

Daniel Mimouni, and Grant J. Anhalt

Pemphigus is an autoimmune blistering disease of the skin with an established immunologic basis but unknown etiology. Its histologic hallmark is the loss of cell-to-cell adhesion (acantholysis) mediated by autoantibodies to epidermal cell surface proteins. Pemphigus has three major variants: pemphigus vulgaris, pemphigus foliaceus, and paraneoplastic pemphigus, which are differentiated by the presence/absence of intraepithelial blisters and erosions of the skin and variable involvement of the mucous membranes. Their associated risks of morbidity and mortality vary greatly

Specific Investigations

- Skin biopsy for routine microscopy
- Skin biopsy for direct immunofluorescence
- Serum for indirect immunofluorescence
- Enzyme-linked immunoassay (ELISA) for antibodies to desmoglein 1 and/or desmoglein 3
- Malignancy screening tests in patients with paraneoplastic pemphigus

Making sense of antigens and antibodies in pemphigus

Anhalt GJ. J Am Acad Dermatol 1999; 40: 763–6.

Accuracy of indirect immunofluorescence testing in the diagnosis of paraneoplastic pemphigus

Helou J, Allbritton J, Anhalt GJ. J Am Acad Dermatol 1995; 32: 441–7.

The diagnosis of pemphigus is established by the fulfillment of three criteria; if one is missing, the diagnosis is uncertain:

- Appropriate clinical features
- Histologic changes showing acantholysis of affected epithelium
- Demonstration of IgG autoantibodies on the cell surface of affected epithelium or detection of antigen-specific autoantibodies in the blood

Pemphigus vulgaris is characterized by progressively evolving fragile blisters and erosions. Oral involvement essentially “always” occurs and is the major point to differentiate pemphigus vulgaris from pemphigus foliaceus. Histologic changes include suprabasilar acantholysis and cell surface-bound IgG. Circulating autoantibodies are specific for desmoglein 3 alone when lesions are restricted to the mouth and for both desmoglein 3 and 1 when cutaneous lesions are present in addition to oral lesions. Definition of the specificity of desmoglein autoantibodies can be reliably gained by ELISA.

In pemphigus foliaceus, mucosal lesions “never” occur. This is the major clinical feature differentiating pemphigus foliaceus from pemphigus vulgaris. The cutaneous lesions are superficial scaling erosions. Immunopathologic studies reveal subcorneal acantholysis and tissue-bound and circulating antidesmoglein 1 antibodies.

Paraneoplastic pemphigus occurs in the context of several lymphoproliferative disorders: non-Hodgkin lymphoma, chronic

lymphocytic leukemia, Castleman disease, thymoma, and retroperitoneal sarcoma. Intractable mucositis with lichenoid erosions is the most constant clinical finding. Polymorphous cutaneous involvement with lesions that resemble erythema multiforme, pemphigus, pemphigoid, or lichenoid eruptions is observed. Histologic study shows suprabasilar acantholysis or interface/lichenoid changes. The key diagnostic finding is the presence of antibodies against desmoglein 3 and 1 and additional autoantibodies against epithelial plakin proteins, such as desmoplakin, envoplakin, and periplakin, which may be identified by immunoblotting or immunoprecipitation techniques. They may also be inferred with immunofluorescent techniques showing their reactivity with murine bladder epithelium, although the lichenoid variant of paraneoplastic pemphigus has been occasionally reported with the complete absence of the characteristic autoantibodies.

Management Strategy

If pemphigus vulgaris is not treated definitively and promptly, the process “hardens,” leading to epitope spreading, which makes the disease more difficult to control. Even if the initial presentation is limited, without systemic treatment, it will generalize. Animal studies have clearly shown that once enough autoantibody reaches the skin, blistering will occur, and this damage cannot be prevented by antiinflammatory agents or even pretreatment with high doses of *systemic corticosteroids*. Topical treatment of the mucous membranes or skin has no significant effect on the course of the disease, though *topical corticosteroids* or *intralesional injections of corticosteroids* may temporarily relieve pain and inflammation.

Other factors complicate management and include the following:

- 1. Circulating autoantibodies have a degradative half-life of about 3 weeks. Lasting improvement can only occur with reduction of both existing and newly produced antibody, so improvement occurs very slowly unless the antibodies are physically removed by plasmapheresis, or their catabolism is increased by administration of high doses of exogenous normal human immunoglobulins (IVIG).**
- 2. Pemphigus is notorious for its persistence. Spontaneous remissions typically do not occur, and remissions and relapses are common. Most people require some form of treatment for life.**

Only a small repertoire of drugs is effective in reducing autoantibody synthesis, but these drugs are limited by high cost and potential toxicities.

3. All forms of pemphigus are rare, precluding the performance of large controlled trials. The medical literature discussing therapeutic regimens is dominated by small series and case reports, which provide only a weak evidence base for the design of rational therapeutic regimens. However, there are excellent animal models of pemphigus, which have given clinicians a good understanding of the pathophysiology of the disease and are instrumental in the formulation of the treatment approach.

Thus the primary goal of treatment in all forms of pemphigus is to reduce the synthesis of autoantibodies by the immune system. It currently consists of three basic steps:

1. Administration of *rituximab* with systemic corticosteroids with the additional use of IVIG
2. Administration of *rituximab* with systemic corticosteroids plus an antimetabolite such as *azathioprine* or *mycophenolate mofetil* (MMF)
3. If *rituximab* is not applicable, corticosteroids plus cyclophosphamide with a possible addition of short-term plasmapheresis

The commitment to the use of cyclophosphamide is a serious one. This drug is extremely effective, but use of this alkylating agent is accompanied by short-term leucopenia and a long-term increased risk of leukemia, lymphoma, and bladder cancer, as well as the risk of sterility in younger patients. The increasing use of *rituximab* is being explored as a way to avert having to use cyclophosphamide.

All types of pemphigus are rare, making large controlled trials difficult to perform. The medical literature on therapeutic regimens is dominated by small series and case reports, which provide a weak evidence base for the design of rational treatment. Some studies have suggested other potential drugs, but they cannot yet be applied because the mechanism whereby they might effectively inhibit new antibody synthesis is unknown. This list includes tetracycline and niacin (nicotinamide), methotrexate, dapsone, and gold. A well-performed randomized trial showed no corticosteroid-sparing benefit of ciclosporin. It is therefore not recommended for the treatment of pemphigus vulgaris, although it may still play a role in the treatment of paraneoplastic pemphigus.

First-Line Therapies

Pemphigus vulgaris and foliaceus

• Systemic corticosteroids	B
• Rituximab	D

Pemphigus: a 20 year review of 107 patients treated with corticosteroids

Rosenberg FR, Sanders S, Nelson CT. Arch Dermatol 1976; 112: 962–70.

The first-line therapy for all forms of pemphigus is systemic corticosteroids. Corticosteroids work relatively quickly and are relatively safe when used in appropriate doses for limited periods. In the past, regimens of rapidly accelerating doses of corticosteroids were administered, but they were found to be associated with unacceptably high morbidity and mortality risks. Initial treatment should start at 1 mg/kg daily (lean body weight). A good clinical response, defined as a resolution of the majority of existing lesions and absence of newly developing lesions, should be evident within 2 to 3 months. The dose should then be reduced to 40 mg daily and subsequently tapered over 6 to 9 months, ideally to a maintenance dose of 5 mg every other day. Tapering can be accomplished by reducing the prednisone by an average of 10 mg per month initially and 5 mg per month later. There are some advantages to beginning an alternate-dose regimen at 40 mg daily so that monthly reductions would ideally be 40/20 mg alternate days, 40/0 mg, 30/0 mg, 20/0 mg, 15/0 mg, and 10/0 mg and then 5/0 mg alternate days for maintenance.

In recent years there is more evidence that the addition of rituximab early in the course of the disease provides a safe and extremely effective treatment that allows an accelerated tapering of systemic corticosteroids, minimizing their devastating side effects.

The use of a second-line therapy is certainly indicated if significant corticosteroid side effects develop or are expected to develop during the ideal

prednisone taper, if the disease does not improve sufficiently to allow continuous tapering, or the disease flares. With the introduction of better tolerated drugs such as MMF, it is reasonable to use a second agent from the start of therapy in all patients with moderate to severe disease from the start of therapy, in anticipation of steroid-sparing benefits.

Monthly pulse corticosteroids have been suggested as a less toxic alternative to daily oral therapy, but pemphigus is very persistent, and more consistent daily or alternate-day dosing is usually required to achieve suppression.

Patients must be monitored for corticosteroid-induced osteopenia by bone mineral density studies (DEXA scan) at the institution of therapy and annually thereafter. Patients without a history of renal calculi may be given prophylactic supplemental calcium 1500 mg daily and vitamin D 400 to 800 IU daily. In patients with osteopenia or osteoporosis, additional therapies may include hormonal replacement in women (estrogen/progesterone or raloxifene in those with a contraindication for estrogens, such as a history of breast carcinoma) or exogenous testosterone in men with low serum testosterone levels or a bisphosphonate such as alendronate or intranasal calcitonin.

In pemphigus vulgaris, therapy as outlined should commence in all patients once the diagnosis is confirmed. Even in cases with limited oral lesions, the disease will progress unless treated with systemic agents, and palliative therapy with topical agents or intralesional injections just delays definitive therapy. There is clinical evidence that early intervention with definitive treatment leads to a better long-term outcome. In pemphigus foliaceus, however, not every patient requires immediate treatment. Some patients have a very limited and smoldering disease and can therefore benefit from palliative treatment, such as topical corticosteroids. In cases of slowly progressive disease one can also consider the use of rituximab as monotherapy. Paraneoplastic pemphigus is usually relentlessly progressive, justifying the immediate institution of systemic corticosteroids and a second-line treatment. If a patient has an associated benign lymphoproliferative disorder, such as thymoma, hyaline vascular Castleman disease, or sarcoma, complete surgical removal should be attempted to prolong disease remission.

Successful treatment of pemphigus with biweekly one gram infusions of rituximab: a retrospective study of 47 patients

Leshem YA, Hodak E, David M, Anhalt GJ, Mimouni D. J Am Acad Dermatol 2013; 68: 404–11.

The aim of this study was to assess the clinical response of patients

with pemphigus to a single cycle of rituximab at the dosage used in rheumatoid arthritis (RA) and to evaluate the response to repeated cycles of rituximab. Remission rates after the first treatment cycle reached 76%. Repeating the treatment further increased the remission rates to 91%. There was a 22% relapse rate at a median time of 8 months, but 75% of relapsing patients achieved remission again with additional cycles.

Treatment of refractory pemphigus vulgaris with rituximab (anti-CD20 monoclonal antibody)

Dupuy A, Viguier M, Bedane C, Cordoliani F, Blaise S, Aucouturier F, et al. *Arch Dermatol* 2004; 140: 91–6.

A single cycle of rituximab for the treatment of severe pemphigus

Joly P, Mouquet H, Roujeau JC, D'Incan M, Gilbert D, Jacquot S, et al. *N Engl J Med* 2007; 357: 545–53.

Twenty-one patients with pemphigus that was refractory to corticosteroids (at least two relapses despite prednisone treatment with doses higher than 20 mg per day; corticosteroid-dependent disease) or who had severe contraindications to corticosteroids were treated with four weekly infusions of rituximab, 375 mg/m² body surface area. Eighteen showed complete remission at 3 months.

Efficacy of rituximab for pemphigus: a systematic review and meta-analysis of different regimens

Wang H, Wei Liu C, Li Y, Huang Y. *Acta Derm Venereol* 2015; 95: 928–32.

This meta-analysis examined the efficacy of different dosing regimens containing rituximab in treating pemphigus. The analysis included 578 patients with pemphigus from 30 studies. Seventy-six percent of patients achieved complete remission after one cycle of rituximab. No superiority of lymphoma protocol over RA or high-dose rituximab over low-dose rituximab was shown in outcome.

Durable remission of pemphigus with a fixed-dose rituximab protocol

Heelan K, Al-Mohammed F, Smith MJ, Knowles S, Lansang P, Walsh S, et al. *JAMA Dermatol* 2014; 150: 703–8.

Ninety-two patients received rituximab. Complete remission rates

with or without adjuvant treatment at final follow-up were 89%. No serious infectious adverse events occurred.

Subcutaneous veltuzumab, a humanized anti-CD20 antibody, in the treatment of refractory pemphigus vulgaris

Ellebrecht CT, Choi EJ, Allman DM, Tsai DE, Wegener WA, Goldenberg DM, et al. JAMA Dermatol 2014; 150: 1331–5.

Veltuzumab, a second-generation humanized anti-CD20 antibody, was administered as two 320-mg (188 mg/m²) subcutaneous doses 2 weeks apart to a patient with refractory pemphigus vulgaris, resulting in complete remission of disease off therapy for 2 years. No serious adverse events occurred during 35 months of follow-up.

Depletion of CD20+ B cells by the use of anti-CD20 monoclonal antibody is emerging as a potentially powerful tool in many autoimmune diseases and is approved for use in RA. CD20 is not expressed on pre-B cells or plasma cells, so it is not profoundly immunosuppressive, and the effect only lasts 6 to 10 months, as the CD20+ cells are repopulated from stem cells. Currently approved dosing is 375 mg/m² weekly × 4 for lymphoma or 1000 mg × 2, days 1 and 15, for RA. The original dosing regimen for lymphoma was designed to prevent tumor lysis syndrome in patients with bulky lymphomas. The authors have used the simpler, lower dose RA schedule in a small number of pemphigus vulgaris patients with equivalent efficacy. Toxicity of rituximab is minimal, but the addition of the drug to patients already exposed to corticosteroids and immunosuppressive drugs increases the risk of infection, including one reported fatal case of Pneumocystis jirovecii (formerly known as carinii) pneumonia (PJP) in a patient treated with rituximab and cyclophosphamide. PJP prophylaxis should be considered with the use of this drug. The drug can cause rapid reduction of autoantibody levels in even severely affected cases, with excellent results and often dramatic recoveries. It is possible that a second course of rituximab has an important consolidation role for durable remission. The addition of IVIG to rituximab is reasonable in explosive acute cases; however, according to the current studies its added value in less acute cases is questionable. Rituximab is used most commonly in paraneoplastic pemphigus, where it has a dual role of treating the underlying lymphoproliferative disease as well as the associated autoimmune disease.

Second-Line Therapies

• MMF	B
• Azathioprine	C
• High-dose IVIG	C

Treatment of pemphigus vulgaris and foliaceus with mycophenolate mofetil

Mimouni D, Anhalt GJ, Cummins DL, Kouba DJ, Thorne JE, Nousari HC. Arch Dermatol 2003; 139: 739–42.

Forty-two patients were treated with MMF, 1.5 g twice daily, and standard prednisone therapy. Complete clinical remission was defined as achieving no new lesions with prednisone doses less than 10 mg daily. This was achieved in 70% of patients with pemphigus vulgaris and 55% of patients with pemphigus foliaceus. Therapy was discontinued in only two cases due to adverse effects—one secondary to febrile neutropenia and one for gastrointestinal intolerance.

For pemphigus vulgaris and foliaceus, two effective antimetabolite immunosuppressive drugs are azathioprine and MMF. Mycophenolate has an excellent safety profile, but it is very expensive. Azathioprine appears to be equally effective and is much cheaper, but has much more frequent toxicities. These drugs are added to the systemic corticosteroids, if the indications for their use are met. Once their beneficial effect is observed, the corticosteroids should be progressively tapered, while the second agent is used at full doses for up to 2 to 3 years to induce a durable remission. For both drugs, the doses required are greater than those needed to control other cutaneous diseases because only at high doses does one observe the required inhibition of the synthesis of autoantibodies by B cells.

MMF has approval for two dosing schedules: 1000 mg PO BID in renal transplantation, and 1500 mg PO BID in cardiac transplants. Both dosing regimens have been used in pemphigus, but there is insufficient evidence to recommend one over the other. Onset of action is slow, and remissions are observed in responders after 2 to 12 months of therapy. Monitoring of

complete blood count and liver enzymes should be performed monthly, but cytopenias and hepatotoxicity are rarely observed. Some lymphopenia without neutropenia is common but has no adverse consequences and can correlate with a good clinical effect. Some nausea and diarrhea can occur but improve with dosage reduction. Avoidance of pregnancy is mandatory, as human fetal malformations have occurred with its use.

Azathioprine in the treatment of pemphigus vulgaris. A long term follow-up

Aberer W, Wolff-Schreiner EC, Stingl G, Wolff K. J Am Acad Dermatol 1987; 16: 527–33.

Azathioprine is given in a single daily dose of 3 to 4 mg/kg. At this dose, there is a risk of neutropenia, thrombocytopenia, hepatotoxicity, and severe or debilitating nausea. Monitoring should consist of complete blood count and liver enzymes, initially every 2 weeks. Patients with thiopurine methyltransferase deficiency (TPMT) cannot metabolize the drug effectively and can develop severe pancytopenia during the first 2 months of therapy. Late effects include elevation of liver enzymes and drug fever. The drug also requires 6 to 8 weeks of therapy before its effect on the disease can be judged. The drug is quite effective, but even if one screens patients for TPMT deficiency before starting treatment, the incidence of side effects is greater than with mycophenolate. It is still a useful second-line agent for those who cannot afford mycophenolate. There is also concern that exposure to this drug can increase one's lifetime risk of leukemia or lymphoma, but the risk is very much less than that associated with the use of alkylating agents.

A comparison of oral methylprednisolone plus azathioprine or mycophenolate mofetil for the treatment of pemphigus

Beissert S, Werfel T, Frieling U, Böhm M, Sticherling M, Stadler R, et al. Arch Dermatol 2006; 142: 1447–54.

A prospective, multicenter, randomized, nonblinded clinical trial to compare two parallel groups of patients with pemphigus treated with oral methylprednisolone plus azathioprine or oral methylprednisolone plus MMF. In 13 (72%) of 18 patients with pemphigus receiving oral methylprednisolone and azathioprine, complete remission was achieved after a mean 74 days compared with 20 (95%) of 21 patients receiving oral methylprednisolone and MMF in whom complete remission occurred after a mean 91 days. In

6 (33%) of 18 patients treated with azathioprine, severe adverse effects were documented in contrast to 4 (19%) of 21 patients who received MMF.

Randomized controlled open-label trial of four treatment regimens for pemphigus vulgaris

Chams-Davatchi C, Esmaili N, Daneshpazhooh M, Valikhani M, Balighi K, Hallaji Z, et al. J Am Acad Dermatol 2007; 57: 622–8.

The aim of this randomized study was to compare the efficacy and safety of four treatment regimens for new-onset pemphigus vulgaris ($n = 121$): prednisolone alone, prednisolone plus azathioprine, prednisolone plus mycophenolate mofetil, and prednisolone plus intravenous cyclophosphamide pulse therapy. Results after 1 year were better with adjuvant treatment than with corticosteroid treatment alone. The highest efficacy was noted for azathioprine, followed by cyclophosphamide (pulse therapy), and mycophenolate mofetil. Interestingly, there were no significant differences in side effects among the groups.

High-dose intravenous immune globulin for the treatment of autoimmune blistering diseases

Harman KE, Black MM. Br J Dermatol 1999; 140: 865–74.

Treatment of pemphigus with intravenous immunoglobulin

Bystryn JC, Jiao D, Natow S. J Am Acad Dermatol 2002: 358; 358–63.

Both studies used IVIG in addition to treatment with prednisone and immunosuppressive therapy. IVIG produced a rapid reduction of circulating autoantibody levels, which was accompanied by significant clinical improvement in some cases.

High-dose IVIG can be used for acute control of active pemphigus. This treatment seems to accelerate the catabolism of the autoantibody and reduce circulating levels as effectively as plasmapheresis. It is generally safe and well tolerated but has some risk. A small number of patients can develop thrombotic complications such as deep venous thrombosis or stroke. It is enormously expensive (as much as \$12,000 per treatment for a 70-kg patient) and may lose its effectiveness after repeated treatment cycles. It can be given intravenously at a dose of 2 g/kg body weight, infused in divided doses over 2 to 5 days monthly.

IVIG is used frequently for acute control of severe cases. It can provide disease control for several months while slower acting drugs such as MMF

are used and is safer than plasmapheresis. It can also be used effectively in combination with rituximab. The use of IVIG for extended periods to induce a remission is more controversial and requires better data.

Third-Line Therapies

• Cyclophosphamide	B
• Cyclophosphamide plus plasmapheresis	E
• Chlorambucil	D

Dexamethasone-cyclophosphamide pulse therapy for pemphigus

Pasricha JS, Khaitan BK, Raman RS, Chandra M. Int J Dermatol 1995; 34: 875–82.

Alkylating agents such as cyclophosphamide have a profound effect on inhibition of autoantibody synthesis and are the most effective agents for inducing remission. They also have very significant potential toxicities, which restrict their use to third-line therapy. In countries where the high cost of rituximab limits its use, cyclophosphamide is still frequently used.

Cyclophosphamide is the preferred agent because any neutropenia associated with its use is predictable in onset, and withdrawal of the drug results in rapid recovery of neutrophils (within 1 week to 10 days). There are four ways to administer the drug:

- 1. Daily orally at 2.5 mg/kg. A single morning dose is followed by aggressive fluid consumption throughout the day to rinse metabolites from the bladder and prevent hemorrhagic cystitis. Weekly complete blood counts and urinalysis are required. With this use, a durable remission can be obtained after 18 to 24 months of therapy in almost all cases. This exposure probably increases the patient's lifetime risk of leukemia, lymphoma, or bladder cancer by as much as 5% to 10% over the normal population. This risk is appreciated some 20 to 30 years after treatment. Such treatment can also cause sterility in young patients.**
- 2. Monthly intravenous pulses at a dose of 750 mg/m² body surface area. Monthly intravenous administration reduces the risk of**

hemorrhagic cystitis, but this intermittent use is not as effective in suppressing the disease.

3. Monthly intravenous administration with lower dose oral daily maintenance. This can also be very effective in inducing a remission.

4. Single, very high-dose immunoablative therapy. This experimental treatment is effective in many autoimmune diseases. It employs a dose of intravenous cyclophosphamide of 200 mg/kg, given over 4 days, which induces profound marrow aplasia. Upon recovery, the patients often experience a complete remission. However, unlike the experience with disorders such as aplastic anemia, where remission may last many years, most patients with pemphigus relapse within 2 years of completion of therapy, limiting its usefulness.

Synchronization of plasmapheresis and pulse cyclophosphamide therapy in pemphigus vulgaris

Euler HH, Loffler H, Christophers E. Arch Dermatol 1987; 123: 1205–10.

Plasmapheresis is the only method by which one can rapidly reduce autoantibody levels and is used in patients with very extensive and accelerated disease. Its use involves a total of six high-volume removals (3–3.5 L per removal, three times weekly for 2 consecutive weeks). This must be combined with the concomitant use of systemic corticosteroids and oral or pulse cyclophosphamide. If these drugs are not used, the reduction of autoantibodies removes feedback inhibition to the autoimmune B cells and causes a rebound flare of the disease. This can be blunted only by alkylating agents due to their preferential toxicity to rapidly proliferative B cells. This causes the induction of a durable remission, though cyclophosphamide must still be used at full doses for 18 to 24 months to harden that remission.

The use of chlorambucil with prednisone in the treatment of pemphigus

Shah N, Green AR, Elgart GW, Kerdel F. J Am Acad Dermatol 2000; 42: 85–8.

In patients who develop hemorrhagic cystitis from cyclophosphamide, chlorambucil can be substituted.

Chlorambucil is more difficult to use because the cytopenias induced by it

are more unpredictable and when they occur may take months to resolve.

Ineffectiveness of ciclosporin as an adjuvant to corticosteroids in the treatment of pemphigus

Ioannides D, Chrysomallis F, Bystryn JC. Arch Dermatol 2000; 868: 505–6.

Thirty-three consecutive patients hospitalized with pemphigus vulgaris ($n = 29$) or foliaceus ($n = 4$) were randomized to receive either prednisolone or prednisolone plus ciclosporin, 5 mg/kg daily. The groups were similar in terms of disease severity and demographics. The addition of ciclosporin produced no change in the response to treatment or the total dose of corticosteroid administered. Complications were, however, more common in those patients who received ciclosporin.

Although there are anecdotal cases reporting benefit from the use of ciclosporin, this well-performed study with an impressive number of cases is good evidence that the drug should not be used in pemphigus vulgaris and foliaceus. There is still good anecdotal evidence that ciclosporin may have a role to play in the management of paraneoplastic pemphigus, a disease with a much more complex pathophysiology.

Perforating dermatoses

Roselyn Kellen, and Mark G. Lebwohl

The perforating dermatoses are a varied group of conditions characterized by the transepidermal elimination of dermal material. Four primary conditions are included in the discussion of the perforating disorders:

- Reactive perforating collagenosis, which is characterized by the transepidermal elimination of collagen

- Elastosis perforans serpiginosa (EPS), characterized by transepidermal extrusion of elastic material
- Perforating folliculitis, in which epidermal perforation involves hair follicles
- Kyrle disease, in which dermal connective tissue perforates through the epidermis

Management Strategy

Definitive diagnosis of the perforating disorders depends on the demonstration of transepidermal elimination on skin biopsy.

Differentiation between the different forms of perforating disorders can be accomplished by Masson trichrome stains for collagen (reactive perforating collagenosis), Verhoeff–van Gieson stains for elastic tissue (EPS), and step-sectioning to look for hair follicles (perforating folliculitis). Differentiation between these various disorders may be important, as EPS is associated with other diseases such as pseudoxanthoma elasticum, Down syndrome, osteogenesis imperfecta, Ehlers–Danlos syndrome, Rothmund–Thomson syndrome, Marfan syndrome, and penicillamine treatment. Reactive perforating collagenosis is commonly associated with diabetes and chronic kidney disease.

Acquired perforating dermatoses have been associated with several medications, including sorafenib, natalizumab, azathioprine, and telaprevir. In particular, acquired reactive perforating collagenosis has occurred in patients treated with indinavir, erlotinib, sorafenib, and sirolimus. Perforating folliculitis has been reported in patients treated with tumor necrosis factor- α blockers, nilotinib, lenalidomide, sorafenib; a patient with cystic fibrosis; and a patient who had previously suffered from varicella in the same distribution as the perforating folliculitis lesions.

Management of the perforating diseases involves determination of underlying etiologies. Most often, conditions such as diabetes mellitus and renal failure will be known to the patient who presents with perforating skin lesions. When the underlying cause is not apparent, serum chemistry for renal and liver function tests and oral glucose tolerance test or hemoglobin A_{1c} may be helpful.

Once the diagnosis of underlying diseases is ascertained, treatment is directed at associated symptoms. Pruritus can be managed initially

with *topical* or *intralesional corticosteroids*, *topical anesthetics*, and *menthol*, as well as *oral antihistamines*, but the latter agents are usually not sufficiently effective. Minimizing pruritus is important because many of the perforating disorders typically exhibit a Koebner phenomenon, meaning that lesions develop in traumatized or scratched skin. Topical antipruritic agents such as menthol, phenol, or camphor and topical anesthetics such as lidocaine and pramocaine are useful. *Topical doxepin hydrochloride* or oral antihistamines may also be of some benefit. Trimming the fingernails to minimize trauma to the skin and avoidance of scratching are key elements of treatment. *Topical tretinoin* and *topical tazarotene* have been shown to be effective for some patients. For those patients whose condition is exacerbated by sun exposure, sunscreens may be helpful. Conversely, in patients with renal disease ultraviolet B (UVB) is dramatically effective for pruritus and has been reported to benefit perforating skin lesions as well. If UVB, narrowband UVB, and topical retinoids are ineffective, *oral retinoids*, *allopurinol*, or *antibiotics* can be tried. More recently, case reports have detailed improvement with *amitriptyline* (10–25 mg daily for several weeks) and topical vitamin D analogs, including *tacalcitol* and *maxacalcitol*.

Specific Investigations

- Skin biopsy with Masson trichrome stains and Verhoeff–van Gieson stains
- Serum blood urea nitrogen, creatinine, amino alanine transferase, aspartate amino transferase, alkaline phosphatase, bilirubin, uric acid
- Serum glucose, oral glucose tolerance test, or hemoglobin A_{1c}
- Hepatitis C virus antibodies
- Thyroid function tests

Clinicopathological features of 25 patients with acquired perforating dermatosis

Akoglu G, Emre S, Sungu N, Kurtoglu G, Metin A. Eur J Dermatol 2013; 23: 864–71.

Of the 25 patients with acquired perforating dermatosis, 17 (68%) had acquired reactive perforating collagenosis, 7 patients (28%) had perforating folliculitis, and 1 patient (4%) had Kyrle disease. The most

commonly associated disease was diabetes mellitus (12 patients, 48%). Five patients (20%) had chronic kidney disease, 2 patients had thyroid disease, and 1 patient had hepatitis C.

First-Line Therapies

• Tretinoin 0.1%	D
• Tazarotene gel 0.1%	E
• UVB	E
• Narrowband UVB	D

Familial reactive perforating collagenosis: a clinical, histopathological study of 10 cases

Ramesh V, Sood N, Kubba A, Singh B, Makkar R. J Eur Acad Dermatol Venereol 2007; 21: 766–70.

Ten patients with familial reactive perforating collagenosis were studied. All the patients responded to topical retinoic acid. The authors suggested that sunscreens may benefit patients whose lesions develop in the summer.

Familial reactive perforating collagenosis may be a distinct entity that occurs in infancy or early childhood. It is of interest that sunlight might play a role in the development of this condition, as phototherapy is used therapeutically in adults with perforating disorders.

Tazarotene is an effective therapy for elastosis perforans serpiginosa

Outland JD, Brown TS, Callen JP. Arch Dermatol 2002; 138: 169–71.

A report of two patients with EPS who responded to daily treatment with 0.1% tazarotene gel. A 22-year-old woman had been

treated unsuccessfully with liquid nitrogen cryotherapy, topical tretinoin, oral isotretinoin, and carbon dioxide (CO₂) laser surgery. A 56-year-old woman had failed to respond to cryotherapy, corticosteroids, tretinoin, and triamcinolone acetonide. Both patients were treated with tazarotene. The skin condition of the 22-year-old greatly improved, and that of the 56-year-old improved moderately.

Treatment of acquired perforating dermatosis with narrowband ultraviolet B

Ohe S, Danno K, Sasaki H, Isei T, Okamoto H, Horio TJ. J Am Acad Dermatol 2004; 50: 892–4.

Narrowband UVB resulted in complete clearing in all five patients treated with phototherapy two to three times per week. Narrowband UVB was started at 400 mJ/cm² and increased up to 1500 mJ/cm². Clearing occurred with 10 to 15 treatments. Disease recurred in three patients between 1 and 10 months after discontinuation of narrowband UVB. Two patients remained clear on narrowband UVB maintenance treatment until 7 and 8 months, respectively.

An 8-year-old boy with familial reactive perforating collagenosis affecting the face received narrowband UVB three times a week. After 25 exposures (total cumulative dose of 38,150 mJ/cm²) the lesions completely regressed and the patient was left with scars and pigmentation changes.

Broadband UVB is also a well-established modality for uremic pruritus. Because many patients with perforating diseases have associated renal failure, UVB phototherapy may dramatically benefit pruritus and reduce the number of skin lesions.

Second-Line Therapies

• Allopurinol	D
• Isotretinoin	E
• PUVA	E
• Acitretin	E

Acquired reactive perforating collagenosis: four patients with a giant variant treated with allopurinol

Hoque SR, Ameen M, Holden CA. Br J Dermatol 2006; 154: 759–62.

All four patients failed topical and oral corticosteroids and antibiotics and were started on allopurinol 100 mg once daily despite normal serum uric acid levels. Three of the four experienced dramatic improvement at 2 to 4 months, with prevention of new lesions, a reduction in pruritus, and clearance of existing lesions. The fourth patient died before the follow-up examination.

In another case report, a patient treated with 100 mg allopurinol once daily experienced marked improvement within 4 weeks: the pruritus and the skin lesions resolved, and he was only left with postinflammatory hyperpigmentation. This response was maintained at follow-up 14 months later. Numerous anecdotal reports have documented improvement of perforating disorders with allopurinol treatment, regardless of whether uric acid levels are elevated or normal.

Reactive perforating collagenosis: a condition that may be underdiagnosed

Satchell AC, Crotty K, Lee S. Australas J Dermatol 2001; 42: 284–7.

Three patients with diabetes mellitus were treated for reactive

perforating collagenosis. A 73-year-old woman was treated with 0.5% phenol with 10% glycerine in sorbolene cream. After 1 month of treatment the itch resolved and skin lesions diminished in number and size. A 75-year-old woman responded to treatment with narrowband UVB. The patient received phototherapy three times per week for 2 months, with resolution of her skin lesions. When the condition recurred 6 months later, it again cleared with 3 months of narrowband UVB. A 58-year-old woman who did not respond to corticosteroids, antihistamines, UVB, or PUVA was successfully treated with oral acitretin 25 mg daily, which resolved the itch and cleared the skin lesions.

Kyrle's disease. Effectively treated with isotretinoin

Saleh HA, Lloyd KM, Fatteh S. J Fla Med Assoc 1993; 80: 395–7.

A 63-year-old patient with Kyrle disease and chronic renal failure was treated with oral isotretinoin for 13 weeks. Cutaneous lesions cleared completely.

Reactive perforating collagenosis responsive to PUVA

Serrano G, Aliaga A, Lorente M. Int J Dermatol 1988; 27: 118–9.

A 21-year-old woman with a 10-year history of reactive perforating collagenosis was treated with PUVA four times per week. Improvement was noted in 2 weeks. Lesions stopped developing after completion of PUVA therapy (326 J/cm² total), and no new lesions were noted in over a year of posttreatment observations.

Third-Line Therapies

• Doxycycline	E
• Oral metronidazole	E
• Oral clindamycin	E
• Oral hydroxychloroquine	E
• Imiquimod	E
• Surgical debridement	E
• Cryotherapy	E
• Cantharidin	E
• Ultrapulse laser	E
• CO ₂ laser	E
• Photodynamic therapy	E
• Transcutaneous electrical nerve stimulation (TENS)	E
• Amitriptyline	E
• Tacalcitol, maxacalcitol	E

Successful treatment of acquired reactive perforating collagenosis with doxycycline

Brinkmeier T, Schaller J, Herbst RA, Frosch PJ. *Acta Derm Venereol* 2002; 82: 393–5.

An 87-year-old woman with acquired reactive perforating collagenosis responded to treatment with oral doxycycline 100 mg daily for 2 weeks. Within 5 days of initiation of treatment, new skin lesions ceased to form, and within 10 days of treatment most lesions had healed.

Regression of skin lesions of Kyrle's disease with metronidazole in a diabetic patient

Khalifa M, Slim I, Kaabia N, Bahri F, Trabelsi A, Letaief AO. *J Infect* 2007; 55: e139–40.

Metronidazole 500 mg twice daily for 1 month completely cleared

lesions of Kyrle disease. Lesions did not recur during 12 months of follow-up.

Regression of skin lesions of Kyrle's disease with clindamycin: implications for an infectious component in the etiology of the disease

Kasiakou SK, Peppas G, Kapaskelis AM, Falagas ME. J Infect 2005; 50: 412–6.

A patient with old, uninflamed hyperkeratotic lesions of Kyrle disease and newer inflamed lesions was successfully treated with a combination of oral clindamycin and surgical removal of large lesions.

Sirolimus-induced inflammatory papules with acquired reactive perforating collagenosis

Lübbe J, Sorg O, Malé PJ, Saurat JH, Masouyé I. Dermatology 2008; 216: 239–42.

A patient with acquired reactive perforating collagenosis attributed to sirolimus after liver transplantation responded to oral hydroxychloroquine 200 mg daily even though the sirolimus was continued. Skin remained clear for 6 months, during which time the patient continued on hydroxychloroquine as well as sirolimus.

Imiquimod therapy for elastosis perforans serpiginosa

Kelly SC, Purcell SM. Arch Dermatol 2006; 142: 829–30.

A 14-year-old girl with elastosis perforans serpiginosa was treated with imiquimod cream applied every night for 6 weeks and then three times weekly for the next 4 weeks. After 10 weeks her skin cleared completely.

A new treatment for acquired reactive perforating collagenosis

Oziemski MA, Billson VR, Crosthwaite GL, Zajac J, Varigos GA. Australas J Dermatol 1991; 32: 71–4.

A single patient with reactive perforating collagenosis was successfully treated with surgical debridement and split-skin grafting of the affected areas.

Because skin lesions are often numerous, surgical removal and skin grafting may be impractical.

Elastosis perforans serpiginosa: treatment with liquid nitrogen

cryotherapy and review of the literature

Humphrey S, Hemmati I, Randhawa R, Crawford RI, Hong CH. J Cutan Med Surg 2010; 14: 38–42.

A 13-year-old male with EPS of the face was successfully treated with liquid nitrogen cryotherapy.

Treatment of acquired perforating dermatosis with cantharidin

Wong J, Phelps R, Levitt J. Arch Dermatol 2012; 148: 160–2.

Cantharidin was used to successfully treat the acquired perforating dermatosis in a 65-year-old woman with diabetes and chronic renal failure.

Acquired perforating dermatosis successfully treated with photodynamic therapy

Sezer E, Erkek E. Photodermatol Photoimmunol Photomed 2012; 28: 50–2.

A 60-year-old woman with acquired perforating dermatosis and diabetes mellitus was successfully treated with photodynamic therapy.

Localized idiopathic elastosis perforans serpiginosa effectively treated by the coherent ultrapulse 5000C esthetic laser

Abdullah A, Colloby PS, Foulds IS, Whitcroft I. Int J Dermatol 2000; 39: 719–20.

Portions of lesions of EPS were treated by laser, with complete clearing of treated sites but no changes in untreated sites.

Response of elastosis perforans serpiginosa to pulsed CO₂, Er:YAG, and dye lasers

Saxena M, Tope WD. Dermatol Surg 2003; 29: 677–8.

A 17-year-old male presenting with EPS on the neck was treated with CO₂ laser on the right neck and erbium:yttrium aluminum garnet (Er:YAG) laser on the left neck. Only mild improvement of EPS was achieved, and subtle atrophic scarring occurred on the area treated with the CO₂ laser. The patient then received pulsed dye laser therapy on both sides of the neck, resulting in only minimal improvement of EPS.

Treatment of elastosis perforans serpiginosa with the pinhole

method using a carbon dioxide laser

Yang JH, Han SS, Won CH, Chang SE, Lee MW, Choi JH, et al. *Dermatol Surg* 2011; 37: 524–6.

Conflicting reports concerning the usefulness of the CO₂ laser for EPS suggest that this modality may be useful as a last resort in some, but not all, patients with EPS.

Treatment of pruritus of reactive perforating collagenosis using transcutaneous electrical nerve stimulation

Chan LY, Tang WY, Lo KK. *Eur J Dermatol* 2000; 10: 59–61.

A 47-year-old woman and an 85-year-old woman, each of whom had failed to respond to treatment with topical steroids and antihistamines, received TENS therapy for 1 hour daily over the course of 3 weeks. Skin lesions cleared within 3 months of treatment in both patients.

Effective treatment of uremic pruritus and acquired perforating dermatosis with amitriptyline

Yong A, Chong WS, Tey HL. *Australas J Dermatol* 2014; 55: 54–7.

Two patients with a history of chronic kidney disease were diagnosed with acquired perforating dermatosis, both suffering from severe pruritus. The first patient, whose biopsy was consistent with Kyrle disease, received amitriptyline 25 mg daily. Within 1 week, his itch score markedly decreased and the nodules had flattened. The itch and lesions reappeared after discontinuing amitriptyline but responded to retreatment. The second patient received amitriptyline 10 mg daily and within 2 weeks, the itching resolved and the excoriated papules healed. His dose was later increased to 25 mg daily when the itch reappeared.

Tacalcitol in the treatment of acquired perforating collagenosis

Escribano-Stable JC, Domenech C, Matarredona J, Pascual JC, Jaen A, Vicente J. *Case Rep Dermatol* 2014; 6: 69–73.

A 65-year-old patient who had failed topical corticosteroids and antihistamines achieved complete remission after 2 months of topical tacalcitol once daily. The lesions returned 4 weeks after finishing treatment but responded to retreatment within 3 weeks.

In a different case report, pruritus and papules resolved after the use of 0.0025% maxacalcitol ointment twice daily (total of 60 g) for 2 months.

Acknowledgment

We would like to thank Sarah Markoff for her contributions to the previous edition of this chapter.

Perioral dermatitis

Antonios Kanelleas, and John Berth-Jones

Perioral dermatitis is a persistent erythematous eruption of inflammatory papules (and sometimes pustules) on the chin, perioral areas, and nasolabial folds, characteristically sparing the skin immediately adjacent to the vermilion border. The main symptoms include pruritus, burning sensation, and soreness. It is usually seen in young women but also occurs in childhood.

The etiology is unknown; however, the development of perioral dermatitis is frequently preceded by intentional or inadvertent application of potent topical corticosteroids to the facial skin. The use

of steroid inhalers may also induce perioral dermatitis. A similar eruption involving the eyelids and periorbital skin has been termed *periocular dermatitis*. The granulomatous subset of perioral dermatitis, which is seen in prepubertal children, presents with small flesh-colored or yellow-brown papules.

The suggested relationship of perioral dermatitis with infectious agents and infestations such as *Candida* spp., *Demodex folliculorum*, and fusiform bacteria has not been confirmed. However, a high prevalence of atopy has been found among patients with perioral dermatitis.

Although sometimes described as a variant of rosacea, perioral dermatitis is distinguished from this disease by its distribution, by the relatively monomorphic appearance of the lesions, by the absence of flushing and telangiectasia, and by its tendency to occur in younger patients. Differential diagnoses also include allergic and irritant contact dermatitis, which does not usually spare the lip margins; acne vulgaris; seborrhoeic dermatitis; and lupus miliaris disseminatus faciei.

Management Strategy

Many cases are associated with the use of *potent topical corticosteroids*, and *withdrawal* of this medication is the most important measure in this group. Patients must be warned that the condition may initially flare after this maneuver. Any cosmetic products applied on the area should also be discontinued. So discontinuation of all topical products is a perfectly acceptable initial approach. If the flare proves intolerable, temporary use of a less potent topical corticosteroid can often be helpful. *Systemic tetracyclines* are also frequently employed, and a range of other modalities are used less frequently. In most cases there will be a permanent remission, but relapses may rarely occur. In case of treatment failure, the possibility of contact allergic dermatitis may need to be investigated by patch testing.

Specific Investigation

- No investigation is routinely required

First-Line Therapies

• Withdrawal of topical corticosteroids	B
• Oral tetracyclines	B

Complications of topical hydrocortisone

Guin JD. J Am Acad Dermatol 1981; 4: 417–22.

Perioral dermatitis developed after the use of topical hydrocortisone.

Although usually associated with the use of potent topical corticosteroids, this case suggests that even hydrocortisone may induce perioral dermatitis.

Perioral dermatitis: aetiology and treatment with tetracycline

Macdonald A, Feiwel M. Br J Dermatol 1972; 87: 351–9.

Tetracycline 250 mg given three times daily for a week, then twice daily for 2 to 3 months, proved highly effective in this series of 29 cases.

Perioral dermatitis in renal transplant recipients maintained on corticosteroids and immunosuppressive therapy

Adams SJ, Davison AM, Cunliffe WJ, Giles GR. Br J Dermatol 1982; 106: 589–92.

A report of five cases where perioral dermatitis developed in patients on oral corticosteroids that could not be discontinued. A 2-month course of doxycycline was effective.

There are also a few recent reports that low-dose doxycycline (40 mg daily) has been useful in perioral dermatitis.

Second-Line Therapies

• Topical pimecrolimus	A
• Topical tetracycline	B
• Topical erythromycin	B
• Oral erythromycin	E
• Topical metronidazole	C
• Topical azelaic acid	D
• Oral isotretinoin	E
• Topical adapalene	E
• Photodynamic therapy	B
• Topical praziquantel	B
• Oral azithromycin	D
• Sodium sulfacetamide lotion	D

Pimecrolimus cream (1%) efficacy in perioral dermatitis: results of a randomized, double-blind, vehicle-controlled study in 40 patients

Oppel T, Pavicic T, Kamann S, Bräutigam M, Wollenberg A. J Eur Acad Dermatol Venereol 2007; 21: 1175–80.

Twenty patients were treated with topical pimecrolimus cream 1% twice a day for 4 weeks. The comparison group consisted of 20 patients treated with the vehicle compound. The Perioral Dermatitis

Severity Index (PODSI) score was found to be significantly lower in the pimecrolimus group at the end of the treatment period, whereas no differences between the two groups were observed after a 4-week follow-up period.

A randomized, double-blind, vehicle-controlled study of 1% pimecrolimus cream in adult patients with perioral dermatitis

Schwarz T, Kreiselmaier I, Bieber T, Thaci D, Simon JC, Meurer M, et al. J Am Acad Dermatol 2008; 59: 34–40.

This multicenter, double-blind trial confirmed the findings of the earlier mentioned study. Patients treated with pimecrolimus also reported greater improvement in quality of life.

There are reports linking the use of topical calcineurin inhibitors with the induction of perioral dermatitis and rosacea-like eruptions after treatment for facial inflammatory dermatoses.

Topical tetracycline in the treatment of perioral dermatitis

Wilson RG. Arch Dermatol 1979; 115: 637.

Topical tetracycline, applied twice daily, proved highly effective in this series of 30 patients. Twenty-four cleared completely after 5 to 28 days.

A topical erythromycin preparation and oral tetracycline for the treatment of perioral dermatitis: a placebo-controlled trial

Weber K, Thurmayr R, Meisinger A. J Dermatol Treat 1993; 4: 57–9.

A comparison of the response to topical erythromycin (33 patients), oral tetracycline (35 patients), and placebo (31 patients). Oral tetracycline and topical erythromycin were comparable in efficacy, and both were superior to placebo.

Topical therapy for perioral dermatitis

Bikowski JB. Cutis 1983; 31: 678–82.

Six cases cleared with topical erythromycin.

Identical twins with perioral dermatitis

Weston WL, Morelli JG. Pediatr Dermatol 1998; 15: 144.

Two cases responded to oral erythromycin.

Topical metronidazole in the treatment of perioral dermatitis

Veien NK, Munkvad JM, Nielsen AO, Niordson AM, Stahl D,

Thormann J. J Am Acad Dermatol 1991; 24: 258–69.

A prospective, randomized, double-blind trial with 109 patients. Both groups improved, but 1% metronidazole cream applied twice daily was less effective than oxytetracycline 250 mg twice daily over 8 weeks.

Topical metronidazole gel (0.75%) for the treatment of perioral dermatitis in children

Miller SR, Shalita AR. J Am Acad Dermatol 1994; 31: 847–8.

Three children with perioral or periocular eruptions were treated with topical metronidazole gel (0.75%) twice daily. Significant improvement was observed after 2 months. Complete resolution occurred after 14 weeks.

Azelaic acid as a new treatment for perioral dermatitis: results from an open study

Jansen T. Br J Dermatol 2004; 151: 933–4.

Ten cases were treated with topical 20% azelaic acid cream applied twice daily. Complete clearing was reported in all cases after 2 to 6 weeks. The cream was well tolerated.

Perioral dermatitis with histopathologic features of granulomatous rosacea: successful treatment with isotretinoin

Smith KW. Cutis 1990; 46: 413–5.

Isotretinoin was used successfully in a resistant case.

Perioral dermatitis successfully treated with topical adapalene

Jansen T. J Eur Acad Dermatol Venereol 2002; 16: 175–7.

Successful treatment of one case of perioral dermatitis with topical adapalene gel once daily for 4 weeks. The patient had had no history of steroid use, and previous topical therapy with erythromycin had failed.

Photodynamic therapy for perioral dermatitis

Richey DF, Hopson B. J Drugs Dermatol 2006; 5: 12–6.

Twenty-one patients participated in this prospective split-face study. One half of the face was treated with 5-aminolevulinic acid (ALA)-PDT once weekly for approximately 4 weeks, and the other half was treated with topical clindamycin once daily. Out of 14 patients who completed the study, the sides treated with PDT had a

mean clearance of 92.1%, compared with 80.9% for the clindamycin sides ($p = 0.0227$). The mean patient satisfaction level for PDT was also higher.

Topical praziquantel as a new treatment for perioral dermatitis: results of a randomized vehicle-controlled pilot study

Bribeche MR, Fedotov VP, Jillella A, Gladichev VV, Pukhalskaya DM. Clin Exp Dermatol 2014; 39: 448–53.

Praziquantel (an anthelmintic drug) 3% was applied as a 3% ointment twice daily for 4 weeks and was found to be superior to vehicle in this study with 46 adult subjects. Dermatology Life Quality Index (DLQI) also improved. No serious treatment-related side effects occurred in either group.

Pediatric periorificial dermatitis: clinical course and treatment outcomes in 222 patients

Goel NS, Burkhart CN, Morrell DS. Pediatr Dermatol 2015; 32: 333–6.

A retrospective review of 222 children treated for perioral and/or periocular dermatitis at a single center. A history of previous steroid use was reported in 58.1% before onset of the disease. Treatments employed included oral azithromycin, topical metronidazole, and sodium sulfacetamide lotion, often combining the systemic antibiotic with a topical modality. Ninety-four (72%) of 131 patients who returned for follow-up had complete resolution of symptoms. Adverse effects included pigmentary changes (1.8%), worsening of symptoms (1.8%), gastrointestinal upset (0.9%), irritant dermatitis (0.9%), and xerosis (0.5%).

Peutz–Jeghers syndrome

Chinmoy Bhate, and Robert A. Schwartz

Peutz–Jeghers syndrome (PJS) is a rare hereditary disorder of polyposis. It is characterized by gastrointestinal polyps, mucocutaneous pigmentation, recurrent abdominal pain from intussusceptions, and an increased risk of intestinal and other malignancies.

The pigmented macules of PJS are typically found around the

mouth, eyes, nostrils, and anus; they may also be seen on the hands and feet. These brown to black macules are often round or oval, 1 to 5 mm in diameter, and irregular in shape. They may occasionally manifest with a blue-gray hue. Clinically and histologically, these are simple lentigines.

Most patients with this autosomal dominant disorder have a germline mutation of the STK11/LKB1 (serine/threonine kinase 11) tumor suppressor gene, located at chromosome 19p13.3. A more recently identified second PJS disease locus exists at 19q13.4. The exact mechanism of cancer and hamartoma development remains unclear. Genetic testing may be useful in equivocal cases, as well as in counseling of at-risk families; however, it is not 100% sensitive.

Management Strategy

Management is predicated upon the potential for visceral complications and familial inheritance. This includes an evaluation for associated findings, including gastrointestinal polyps, which occur in nearly all PJS patients, recurrent intussusceptions, gastrointestinal bleeding, and a variety of other internal malignancies. Disease is most often discovered between the ages of 10 and 30 years. Any child seen with recurrent, unexplained abdominal pain should raise concern for intussusception, a medical emergency associated with PJS.

Gastrointestinal polyps are most often found in the small bowel but may also be seen in the stomach, large bowel, and rectum; these polyps are at risk for malignant degeneration.

Esophagogastroduodenoscopy, capsule endoscopy or balloon enteroscopy, and colonoscopy are important in the evaluation and treatment of gastrointestinal polyposis.

Cancers of the stomach, pancreas, esophagus, lung, uterus, and testes (Sertoli cell) all have an elevated relative risk in patients with PJS. Women with this disorder also carry an increased risk of bilateral breast cancer. Ovarian neoplasms, especially granulosa cell tumors, may be seen. Both in men and women, sex cord tumors with annular tubules and sex cord stromal tumors with sexual precocity may develop.

Genetic testing in suspected cases is critical in order to identify familial or de novo mutations. Genetic counseling of PJS patients and their relatives is indicated. Families should be reassured that the mucocutaneous macules are benign and may improve after puberty.

Several therapies for these pigmented macules have been used with varying responses; removal may potentially mask the underlying disorder in patients with undiagnosed PJS.

The *Q-switched Nd:YAG laser* and *ruby laser (Q-switched and short pulsed)* have been used in the treatment of labial macules without sequelae or recurrences. Anesthesia is not usually required, and minimal wound care is necessary. The *CO₂, alexandrite, and argon lasers*, as well as *intense pulsed light*, have also been effective in the treatment of labial macules. Cryosurgery, surgical excision, electrodesiccation, and dermabrasion may lead to scarring and dyspigmentation, often without complete removal of the pigmented macules. Similarly, *trichloroacetic acid* may not produce total resolution.

Specific Investigations

- Gastrointestinal evaluation
- Genetic testing (in some cases)
- Histology of polyps and mucocutaneous macules (if diagnosis is in question)
- Psychosocial evaluation

Rapid detection of germline mutations for hereditary gastrointestinal polyposis/cancers using HaloPlex target enrichment and high-throughput sequencing technologies

Kohda M, Kumamoto K, Eguchi H, Hirata T, Tada Y, Tanakaya K, et al. *Fam Cancer* 2016; 15: 553–62.

The authors discuss traditional means of molecular diagnostics as well as newer, high-throughput sequencing-based tests; they present methodology that may potentially promote more rapid screening with high efficiency and accuracy.

The STK11/LKB1 gene is one among many that are linked with hereditary gastrointestinal polyposis/cancer syndromes. Genetic testing is widely utilized in routine practice, and newer techniques are being evaluated for more efficiency, accuracy, and turnaround time.

ACG clinical guideline: genetic testing and management of hereditary gastrointestinal cancer syndromes

Syngal S, Brand RE, Church JM, Giardiello FM, Hampel HL, Burt RW.

Am J Gastroenterol 2015; 110: 223–63.

A comprehensive document from the American College of Gastroenterology providing guidelines for evaluation, surveillance, and management of patients with a number of hereditary syndromes, including PJS. This review also provides recommendations for surveillance of associated internal malignancies.

Small bowel endoscopy and Peutz-Jeghers syndrome

Korsse SE, Dewint P, Kuipers EJ, van Leerdam ME. Best Pract Res Clin Gastroenterol 2012; 26: 263–78.

This article provides a systematic review of endoscopic techniques used to examine the small bowel in patients with PJS.

Small bowel surveillance is recommended in patients with PJS every 2 to 3 years from the age of 8 to 10 years. Visualization of the small bowel is technically challenging, and a gold standard method has not been established.

Peutz-Jeghers syndrome: a systematic review and recommendations for management

Beggs AD, Latchford AR, Vasen HF, Moslein G, Alonso A, Aretz S, et al. Gut 2010; 59: 975–86.

A review of current genotype–phenotype studies and an outline of consensus recommendations for screening and follow-up from a group of European experts who previously produced guidelines for the management of Lynch syndrome and familial adenomatous polyposis.

Surveillance in PJS aims to (1) reduce polyp burden and the incidence of intussusceptions in young patients and (2) reduce the burden of cancer. Capsule endoscopy allows for thorough, less invasive surveillance of the small bowel for polyposis. Evaluation of the small bowel with upper gastrointestinal (GI) endoscopy, colonoscopy, and double-balloon enteroscopy has been useful in preventing the need for subsequent surgical polypectomy; because double-balloon enteroscopy is often traumatic, it is reserved as a treatment modality.

Quality of life and psychological distress in patients with Peutz-Jeghers syndrome

Van Lier MG, Mathus-Vliegen EM, van Leerdam ME, Kuipers EJ, Looman CW, Wagner A, et al. Clin Genet 2010; 78: 219–26.

A cross-sectional study in order to assess the quality of life and psychological distress in PJS patients compared with the general

population.

Compared with the general population, PJS patients reported a lower general health perception, more limitations due to emotional problems, and a lower mental well-being.

Genetics of the hamartomatous polyposis syndromes: a molecular review

Chen HM, Fang JY. Int J Colorectal Dis 2009; 24: 865–74.

A discussion of hamartoma syndromes, including clinical features and molecular diagnostic modalities, which help differentiate between them and identify at-risk patients.

Peutz–Jeghers syndrome

Heymann WR. J Am Acad Dermatol 2007; 57: 513–4.

A synopsis of the syndrome correlating molecular advances with the cutaneous, malignant, and endocrinologic features of the disorder.

Further observations on LKB1/STK11 status and cancer risk in Peutz–Jeghers syndrome

Lim W, Hearle N, Shah B, Murday V, Hodgson SV, Lucassen A, et al. Br J Cancer 2003; 89: 308–13.

A genotype–phenotype analysis demonstrating significant genetic heterogeneity in PJS.

The authors demonstrated an elevated relative risk of cancer development in patients with PJS. They also demonstrated that PJS may occur either as a result of several types of mutations within the mentioned gene or even in the absence of a mutation.

Peutz–Jeghers syndrome: confirmation of linkage to chromosome 19p13.3 and identification of a potential second locus, on 19q13.4

Mehenni H, Blouin JL, Radhakrishna U, Bhardwaj SS, Bhardwaj K, Dixit VB, et al. Am J Hum Genet 1997; 61: 1327–34.

The authors described the location of the most prevalent mutation in PJS, the LKB1/STK11 gene at location 19p13.3, and identified an additional locus.

Most patients with PJS have associated LKB1/STK11 mutations at location 19p13.3; however, a second disease locus at 19q13.4 has also been demonstrated. Some patients have no mutation at either site, which serves as a limitation to genetic testing for diagnosis.

Harold Jeghers (1904–1990)

Schwartz RA. In: Löser C, Plewig G, Burgdorf WHC, eds. *Pantheon of Dermatology. Outstanding Historical Figures*. Berlin: Springer Verlag, 2013; 553–6.

A biography of Harold Jeghers is presented with a review of this syndrome that carries his name.

First-Line Therapies

• Q-switched Nd:YAG laser	C
• Ruby and alexandrite lasers	D

Q-switched Nd:YAG laser treatment for labial lentigines associated with Peutz-Jeghers syndrome

J Dtsch Dermatol Ges 2015; 13: 551–5.

Eleven patients with PJS received two to six treatments with Q-switched Nd:YAG laser (532 nm) with a spot size of 3 mm, fluence of 1.8 to 2.2 J/cm², and pulse duration ranging from 5 to 20 ns. Eight of 11 patients had greater than 75% clearance with minimal recurrence or complication after a mean follow-up of 41 months.

Q-switched alexandrite laser treatment of oral labial lentigines in Chinese subjects with Peutz-Jeghers syndrome

Xi Z, Hui Q, Zhong L. *Dermatol Surg* 2009; 35: 1084–8.

Fourteen cases of oral labial lentigines in patients with PJS were managed using a single treatment with Q-switched alexandrite laser with a 3-mm handpiece and a fluence of 4.0 to 9.0 J/cm². All exhibited successful elimination without scarring or recurrence at median 2-year follow-up.

Q-switched lasers, in particular the alexandrite laser, are preferred in the treatment of benign melanocytic lesions, including oral labial lentigines in PJS patients; acute side effects included edema, erythema, and occasional bleeding.

Q-switched ruby laser treatment of labial lentigos

Ashinoff R, Geronemus RG. J Am Acad Dermatol 1992; 27: 809–11.

The Q-switched ruby laser, with a wavelength of 694 nm and pulse duration of 40 ns, causes selective damage to pigmented cells. Three patients with labial lentigines treated with the Q-switched ruby laser noted dramatic clearing after one or two treatments with a fluence of 10 cm².

Ruby laser therapy for labial lentigines in Peutz–Jeghers syndrome

Kato S, Takeyama J, Tanita Y, Ebina K. Eur J Pediatr 1998; 157: 622–4.

Two children with PJS and labial lentigines were treated successfully without sequelae or recurrence.

Q-switched ruby laser treatment of tattoos and benign pigmented lesions: a critical review

Raulin C, Schrmack MP, Greve B, Werner S. Ann Plast Surg 1998; 41: 555–65.

This review discusses indications for the use of the Q-switched ruby laser. These include tattoos, café au lait macules, and lentigines, especially those on the lips and eyelids.

Second-Line Therapies

• Other lasers	E
• Intense pulsed light	E
• Cryotherapy	E

Treatment of Peutz–Jeghers lentigines with the carbon dioxide laser

Benedict LM, Cohen B. J Dermatol Surg Oncol 1991; 17: 954–5.

One patient with PJS had successful treatment of perioral lentigines with a CO₂ laser.

Q-switched alexandrite laser in the treatment of pigmented macules in Laugier–Hunziker syndrome

Papadavid E, Walker NP. J Eur Acad Dermatol Venereol 2001; 15: 468–9.

Two patients with labial pigmented macules were treated with the Q-switched alexandrite laser. Recurrences were easily treated again.

Laugier–Hunziker syndrome, a disorder of mucocutaneous pigmentation similar to PJS, has no associated GI abnormalities. Treatment of pigmented lesions in this syndrome may provide insight into the treatment of those seen in PJS.

Treatment of pigmentation of the lips and oral mucosa in Peutz–Jeghers syndrome using ruby and argon lasers

Ohshiro T, Maruyama Y, Nakajima H, Mima M. Br J Plast Surg 1980; 33: 346–9.

Three PJS patients had successful treatment of pigmented oral macules with ruby and argon lasers.

Treatment of facial lentigines in Peutz–Jeghers syndrome with intense pulsed light source

Remington BK, Remington TK. Dermatol Surg 2002; 28: 1079–81.

A 10-year-old child had complete clearance of cosmetically concerning lentigines over the course of 12 treatment sessions to different facial regions. Most resolved with a single treatment.

This report demonstrated the first use of intense pulsed light in PJS and provided a viable alternative to laser treatment.

Simple cryosurgical treatment of the oral melanotic macule

Yeh CJ. Clin Oral Maxillofac Surg 2000; 90: 12–3.

Simple cryotherapy for labial melanotic macules is discussed; a specific protocol is provided.

Cryosurgery needs no sophisticated equipment and is inexpensive. Recurrence is common, and inadequate destruction may occur.

Chemopreventive efficacy of rapamycin on Peutz-Jeghers syndrome in a mouse model

Wei C, Amos CI, Zhang N, Zhu J, Wang X, Frazier ML. Cancer Lett 2009; 18: 149–54.

Rapamycin treatment of mice with LKB1 mutations led to a reduction in both polyp burden and polyp size, suggesting that rapamycin may be an option for chemoprevention in humans with PJS.

Suppression of Peutz-Jeghers polyposis by targeting mammalian target of rapamycin signaling

Wei C, Amos CI, Zhang N, Wang X, Rashid A, Walker CL, et al. Clin Cancer Res 2008; 14: 1167–71.

Mice with germline LKB1 mutations and polyposis were treated with rapamycin at the dose of 2 mg/kg/d for 2 months. Rapamycin decreased the tumor burden of large polyps (>8 mm).

Rapamycin effectively suppresses Peutz–Jeghers polyposis in a mouse model, suggesting that it and other inhibitors of the mammalian target of rapamycin (mTOR) may represent targeted therapy for this disorder.

Pinta and yaws

Omar Lupi, Daniela Martinez, and Helena Camasmie

Pinta and yaws belong to the group of neglected, endemic, and nonvenereal treponematoses. These distinct and chronic diseases predominantly affect economically disadvantaged, isolated, rural areas of tropical and subtropical countries.

Yaws is currently thought to be endemic in 14 countries, mostly in West Africa, Southeast Asia and the Pacific, whereas pinta is restricted to Latin America, in particular Mexico and Colombia. Pinta is caused by *Treponema carateum*, and yaws is caused by *Treponema pallidum* ssp. *pertenue*. Both are gram-negative spirochetes, morphologically and antigenically identical to each other and to the etiologic agent of syphilis; therefore specification has to be based on clinical and epidemiologic aspects. The only known reservoir is humans.

Management Strategy

Both treponematoses are transmitted by direct skin contact through breaks in the skin from small cuts, scratches, or other skin damage. Most patients acquire the infection during childhood. Both diseases comprise multiple stages.

Pinta is considered the most benign among them, with skin-limited manifestations. It is classified into two different clinical stages. The primary stage is divided into two phases: an early phase (initial period) and a secondary phase (period of cutaneous dissemination). The primary lesions appear 7 to 10 days after inoculation and are characterized by erythematous papules on the face and upper and lower extremities. These lesions tend to grow, producing erythemasquamous or hyperpigmented asymptomatic plaques. Within 6 months to 2 to 3 years of the first appearance of lesions, erythemahypochromic patches appear, initiating the period of cutaneous dissemination. They are polymorphic and referred to as *pintides*, affecting larger areas of the body with normal skin in the center.

The hallmark of the late stage, 2 to 5 years after the first lesion, is the appearance of achromic patches, especially over body prominences. Plantar hyperkeratosis is frequent. There is no evidence of involvement of other organs, even after many years.

The initial lesion of yaws is called *mother yaws*, arising at the site of entry of the organism, most commonly on the lower limbs, 21 days after inoculation. *Mother yaws* is an erythematous infiltrated papule or a group of papules on an erythematous base, which may ulcerate. They are painless and considered highly infectious. *Mother yaws* frequently heals spontaneously, leaving an atrophic and hypopigmented scar. Systemic symptoms such as fever and joint pain

are sometimes present, as well as regional lymphadenopathy.

Disseminated cutaneous lesions appear in untreated cases after healing of the initial lesion. Characterizing the secondary stage: a bilateral and symmetric eruption that may be present in two main clinical features: a large one that resembles the mother yaws and is called *daughter yaws* and a micropapular type, called *miniature yaws*. The mostly affected locations are the face and intertriginous moist surfaces. Usually the soles present hyperkeratotic plaques with fissures and pain, forcing the patients to walk with a peculiar gait known as *crab yaws*. Cutaneous lesions usually heal, leaving a hypochromic area. Painful osteoperiostitis and polydactylitis may occur, as well as systemic symptoms (fever, headache, generalized adenopathy, and nocturnal bone pain).

Late tertiary yaws appears in 10% of cases after several years, involving subcutaneous tissues, mucous membranes, bones, and joints. The presence of neurologic, cardiovascular, and ophthalmologic lesions is very controversial. The lesions of late yaws are characterized by nodular and tubercular pianides, gummatous lesions, palmar and plantar keratoderma, osteoarticular lesions, palate and nasal septum destruction (*gangosa*), exostoses of the nasal bridge (*goundou*), and juxtaarticular nodes.

Serologic tests, such as rapid plasma reagin (RPR), venereal disease research laboratory (VDRL), FTA-ABS and *Treponema pallidum* particle agglutination (TPPA) and hemagglutination (TPHA) assays remain the cornerstone of the diagnosis, although they cannot distinguish syphilis from any of the nonvenereal treponematoses. Dark-field microscopic examination, radiologic, and histopathologic studies have also been used. Pathogenic treponemes cannot be cultured in vitro. *T. pallidum* PCR assays can be applied to the diagnosis of endemic treponematoses as a direct method with high sensitivity. Access to these facilities may be difficult for the affected, isolated, rural communities, which brings difficulty to the diagnosis.

There is no proof of a spontaneous cure for the disease, and because cell-mediated immunity is not completely effective, the infection persists indefinitely. Patients may harbor subclinical disease and be contagious for a long time.

Intramuscular *benzathine penicillin* remains the mainstay of treatment for the endemic treponemal diseases for over 50 years. A single dose is effective, which ranges from 1.2 million units for patients over 10 years old, with half the dose necessary for patients

aged under 10 and contacts.

World Health Organization (WHO) programs in the 1950s to 1960s successfully reduced the number of cases of yaws by administering single-dose penicillin, but failure to adequately identify and treat contacts and latent cases led to noneradication of the disease.

A study was conducted in infected children with a 30 mg/kg single oral dose of *azithromycin*, and it was proven to be noninferior to penicillin, with the benefit of avoiding the need for injection equipment and medically trained personnel. Changing to the simpler azithromycin treatment regimen could enable yaws elimination through mass drug administration programs, renewing WHO efforts to eradicate the disease by 2020. Six-month follow-up includes clinical and serologic surveys to detect and treat remaining cases and their contacts. Awareness to the possibility of azithromycin resistance is important, as it has occurred in syphilis.

At present the WHO has not yet developed a specific strategy for the control or eradication of pinta.

Specific Investigations

- Serologic tests
- Dark-field microscopy
- Direct fluorescent antibody test
- Histopathology
- PCR

Yaws

Marks M, Mitjà O, Solomon AW, Asiedu KB, Mabey DC. Br Med Bull. 2015; 113: 91–100.

Dark field microscopy allows direct visualization of spirochaetes.

Genetic diversity in *Treponema pallidum*: implications for pathogenesis, evolution and molecular diagnostics of syphilis and yaws

Smajs D, Norris SJ, Weinstock GM. Infect Genet Evol 2012; 12: 191–202.

Genome analyses also shed light on treponemal evolution and on chromosomal targets for molecular diagnostics of treponemal infections.

A retrospective study on genetic heterogeneity within *Treponema* strains: subpopulations are genetically distinct in a limited number of positions

Čejková D, Strouhal M, Norris SJ, Weinstock GM, Šmajš D. PLoS Negl Trop 2015; 9: e0004110.

Heterogeneous sites likely represent both the selection of adaptive changes during infection of the host and an ongoing diversifying evolutionary process.

Advances in the diagnosis of endemic treponematoses: yaws, bejel, and pinta

Mitjà O, Šmajš D, Bassat Q. PLoS Negl Trop Dis 2013; 7: e2283.

Serologic tests are still considered standard laboratory methods for the diagnosis of endemic treponematoses, and new rapid point-of-care treponemal tests have become available. In the past 10 years, there has been an increasing effort to apply polymerase chain reaction to treponematoses, and whole genome fingerprinting techniques have identified genetic signatures that can differentiate the existing treponemal strains.

Histopathology is important in diagnosis. It is possible to demonstrate the presence of the treponeme in the epidermis through Warthin–Starry staining in all lesions, with the exception of achromic lesions.

First-Line Therapies

• Penicillin G benzathine	B
• Azithromycin (yaws)	B

Pinta: Latin America's forgotten disease?

Stamm LV. Am J Trop Med Hyg 2015; 93: 901–3.

All stages of pinta are treatable with a single intramuscular injection of penicillin.

Serologic cross-reactivity of syphilis, yaws, and pinta

De Caprariis PJ, Della-Latta P. *Am Fam Physician* 2013; 15; 87: 80.

Penicillin G benzathine is the recommended treatment for all three treponemal diseases; a single dose is adequate for yaws, pinta, and primary syphilis, but inadequate for late latent and tertiary syphilis.

Endemic treponemal diseases

Marks M, Solomon AW, Mabey DC. *Trans R Soc Trop Med Hyg* 2014; 108: 601–7.

For endemic treponemal diseases a dose of 1.2 million units is recommended for patients aged 10 or over, whereas a dose of 0.6 million units is recommended for patients aged under 10 and for contacts.

Single-dose azithromycin versus benzathine benzylpenicillin for treatment of yaws in children in Papua New Guinea: an open-label, non-inferiority, randomised trial

Mitjà O, Hays R, Ipai A, Penias M, Paru R, de Lazzari E et al. *Lancet* 2012; 379: 342–47.

A single dose of oral azithromycin (30 mg/kg with a maximum of 2 g) is as effective as intramuscular benzathine penicillin for treatment of yaws in children in Papua New Guinea.

Yaws: renewed hope for eradication

Stamm LV. *JAMA Dermatol* 2014; 150: 933–34.

Although azithromycin is safer than penicillin and should make mass treatment significantly easier, its use will require monitoring for emergence of resistance due to 23S ribosomal RNA point mutations, as observed with the syphilis agent.

Second-Line Therapies

• Tetracycline	E
• Doxycycline	E
• Erythromycin	E

Yaws in the Western Pacific region: a review of the literature

Capuano C, Ozaki M. J Trop Med 2011; 2011: 1–15.

Tetracycline, erythromycin, or doxycycline can be used for patients with penicillin hypersensitivity.

New treatment schemes for yaws: the path toward eradication

Mitjà O, Hays R, Rinaldi AC, McDermott R, Bassat Q. Clin Infect Dis 2012; 55: 406–12.

Oral tetracycline, doxycycline, or erythromycin for 15 days is also likely to be effective. These recommendations, however, are based solely upon known clinical efficacy in small series of patients and not upon the results of any clinical trials

Endemic treponematoses: review and update

Farnsworth N, Rosen T. Clin Dermatol 2006; 24: 181–90.

Penicillin remains the drug of choice, but the tetracycline class of antibiotics and erythromycin also appear to be effective.

Tropical dermatology: bacterial tropical diseases

Lupi O, Madkan V, Tyring SK. J Am Acad Dermatol 2006; 54: 559–78.

This is a large update on bacterial tropical diseases, including pinta and yaws. Alternative therapies such as tetracycline or erythromycin are discussed.

Pitted and ringed keratolysis (keratolysis plantare sulcatum)

Eunice Tan, and John Berth-Jones

Pitted keratolysis (PK) manifests as shallow, punched-out, circular erosions, primarily on weight-bearing, sweaty areas of the feet, and less commonly on the non-weight-bearing areas of the feet and the palms of the hands. This superficial infection of the stratum corneum is caused by *Corynebacterium*, *Dermatophilus*, *Actinomyces*, or *Kytococcus* (formerly named *Micrococcus*). These organisms possess keratin-degrading enzymes and produce sulfur compounds, resulting in a foul odor. Hyperhidrosis and maceration often occur concurrently.

Management Strategy

Most patients experience little or mild irritation. Maceration, foul odor, and soreness are the main reasons for consultation.

Hyperhidrosis, sweat retention, prolonged occlusion, immersion, and increases in the skin pH appear to be important causes of PK.

Industrial workers wearing rubber shoes or soldiers whose feet are continually occluded or wet are at high risk of developing this infection. Initial management strategies should therefore include instruction on *foot hygiene* and *avoidance of occlusive footwear*.

Treatment involves use of topical or systemic antimicrobial agents and/or reduction of the hyperhidrosis.

The topical antibiotic most commonly used by the authors is *fusidic acid*, which can be prescribed as 2% fusidic acid cream or ointment three to four times daily for a week. Topical 1% *clindamycin*, *benzoyl peroxide*, 1% *clindamycin with 5% benzoyl peroxide gel*, 2% or 3% *erythromycin*, *mupirocin ointment*, and *tetracycline and gentamicin sulfate cream* have been reported to be effective. Although 1% clindamycin hydrochloride can be made up with 660 mg dissolved in 55 mL of 70% isopropyl alcohol and 5% propylene glycol, we suggest Dalacin T topical solution may be used instead. This can be applied two or three times daily. Erythromycin 2% cream or ointment has been reported to be effective if used twice daily. We suggest using 2% erythromycin gel, available as Eryacne, or 2% erythromycin solution, available as Stiemycin. Japanese dermatologists have had some success in treating PK with gentamicin sulfate cream, but this is unavailable in the UK. Mupirocin 2% ointment may be administered two to three times daily; 3% tetracycline hydrochloride ointment may be applied one to three times daily. PK has also responded to topical antifungals such

as *clotrimazole* and *miconazole*; 1% clotrimazole cream or 2% miconazole cream or ointment may be applied twice daily. Topical antiseptics can be effective.

Systemic antibiotics can be reserved for severe and resistant cases. A 7-day course of oral erythromycin 250 mg four times a day is usually well tolerated. The use of penicillin or sulfonamides does not seem to be effective. Antibiotic resistance has been reported with *Micrococcus sedentarius* to penicillin, methicillin, ampicillin, oxacillin, and erythromycin.

Topical 20% *aluminum chloride hexahydrate* in absolute anhydrous ethyl alcohol, available as Driclor, may reduce hyperhidrosis and odor, but the pits remain. The solution is applied at night, allowed to dry, and washed off the next day. Initially it should be used daily until the condition is brought under control, when it can be used less frequently. The use of 20% aluminum chloride hexahydrate for palmoplantar hyperhidrosis has not been as successful as its use for axillary hyperhidrosis. Topical 4% *formaldehyde solution* applied with gauze soaks as the patient sits or stands with his or her feet on the gauze in a bowl for 10 to 15 minutes once or twice daily reduces the hyperhidrosis. Alternatively, immersion of the soles of the feet in 5% *formaldehyde* may be utilized. Formalin ointment 40% has been used with some success but is not commercially available in the UK.

Topical 2% *glutaraldehyde* has been reported to have good therapeutic results in PK but sometimes the patient may require the 10% strength to reduce hyperhidrosis. Glutaraldehyde is available in the UK as Cidex (25% or 50% strength), which is used for instrument sterilization, and is somewhat hazardous to handle. Like formaldehyde, glutaraldehyde may cause contact sensitization, but it does not cross-react with formaldehyde.

Iontophoresis is frequently used in palmar and plantar hyperhidrosis and can be used in the treatment of PK. *Botulinum toxin* has also been used. Oral anticholinergics are perhaps excessive.

Various other agents have been tried topically but with limited success. These include 0.1% *triamcinolone acetonide* once or twice daily, *iodochlorhydroxyquin-hydrocortisone cream* (vioform-hydrocortisone) once or twice daily, *flexible collodion*, *Whitfield ointment* (6% benzoic and 3% salicylic acid ointment in a petrolatum base) twice daily, and Castellani paint. Water-repellent silicone ointment has been found not to significantly improve PK.

Specific Investigations

No investigation is routinely required

- Wood light examination may reveal a coral red fluorescence, but this is not consistently helpful
- Dermoscopy may reveal small black pits in a parallel pattern on the ridges of the stratum corneum
- Starch iodine test may identify areas of hyperhidrosis
- Shave biopsies processed with methenamine silver stain, Gram stain, or periodic acid–Schiff stains are more helpful than punch biopsies
- Swabs may be obtained for cultures of the organisms

Pitted keratolysis. The role of *Micrococcus sedentarius*

Nordstrom KM, McGinley KJ, Cappiello L, Zechman JM, Leyden JJ. Arch Dermatol 1987; 123: 1320–5.

Micrococcus sedentarius isolated from PK lesions on the feet of eight patients was tested for antibiotic sensitivities and found to be resistant to penicillin, ampicillin, methicillin, and oxacillin. PK lesions were reproduced in one volunteer inoculated with *M. sedentarius* after 6 weeks of occlusion.

Isolation and characterization of micrococci from human skin, including two new species: *Micrococcus lylae* and *Micrococcus kristinae*

Kloos WE, Torrabene TG, Schleifer KH. Int J Syst Bacteriol 1974; 24: 79–101.

M. sedentarius was observed to be resistant to penicillin, methicillin, and erythromycin, which is characteristic of the genus *Micrococcus*.

First-Line Therapies

• Topical fusidic acid	E
• Topical aluminum chloride hexahydrate	E

Isolation of *Kytococcus sedentarius* from a case of pitted keratolysis

Ertam İ, Aytimur D, Yüksel SE. Ege Tıp Dergisi 2005; 44: 117–8.

A case report of a patient with plantar PK in which *Kytococcus* was isolated, with complete response to 3 weeks of oral erythromycin and topical fusidic acid.

Second-Line Therapies

• Topical mupirocin	E
• Topical tetracyclines	E
• Topical clindamycin	D
• Topical clotrimazole	E
• Topical benzoyl peroxide	D
• Topical erythromycin	C
• Topical miconazole	E
• Oral erythromycin	E
• Topical formaldehyde	E

Pitted keratolysis: successful management with mupirocin 2% ointment monotherapy

Greywal T, Cohen PR. Dermatol Online J 2015; 15: 21.

Complete resolution of a patient with pitted keratolysis occurred

after monotherapy with twice-daily application of mupirocin 2% ointment for a duration of 3 weeks. There was no recurrence at a follow-up visit 8 weeks later.

P1606 *Kytococcus sedentarius* nail infection

Towerser L, Azulay RD, Filho PJS, Fischman-Gompertz O, Hay RJ. J Am Acad Dermatol Supplement 2008; 58: AB88.

A case report of a patient with *Kytococcus* PK and associated nail dystrophy responding to systemic amoxicillin and potassium clavulanate, topical mupirocin cream for feet lesions, and gentamicin sulfate solution for nail lesions.

Pitted keratolysis: a new form of treatment [Letter]

Burkhart CG. Arch Dermatol 1980; 116: 1104.

Three patients with PK were treated with topical 1% clindamycin hydrochloride solution (660 mg dissolved in 55 mL of 70% isopropyl alcohol and 5% propylene glycol). The solution was applied to the plantar surface three times daily, and within 4 weeks there was complete resolution of the clinical lesions.

Road rash with a rotten odor

Schissel DJ, Aydelotte J, Keller R. Military Med 1999; 164: 65–7.

Case report of a soldier treated with topical clotrimazole cream twice a day, topical clindamycin solution twice a day, and topical ammonium chloride each evening. At his 2-week follow-up appointment, he reported resolution of the odor, tenderness, and interdigital pruritus, and at 8 weeks he had complete resolution.

The use of a clindamycin 1%-benzoyl peroxide 5% topical gel in the treatment of pitted keratolysis: a novel therapy

Vlahovic TC, Dunne SP, Kemp K. Adv Skin Wound Care 2009; 22: 564–6.

The combination topical gel of clindamycin 1% with benzoyl peroxide 5% was reported to be effective in four patients, but efficacy required the concurrent use of aluminum chloride hexahydrate solution.

Comparative study of benzoyl peroxide versus clindamycin phosphate in treatment of pitted keratolysis

Kim BJ, Park KU, Kim JY, Ahn JY, Won CH, Lee JH, et al. Korean J

Med Mycol 2005; 10: 144–50.

A total of 44 patients with PK were reported in this study. Seventeen received benzoyl peroxide alone, 15 received clindamycin alone, and 12 received combination benzoyl peroxide and clindamycin therapy. There was no difference in treatment efficacy between monotherapy or combination therapy. Although not significant, the clindamycin group had a slightly higher recurrence rate. Four cases recurred within 3 months and all were related to hyperhidrosis.

Pitted keratolysis: a clinicopathologic review

Stanton RL, Schwartz RA, Aly R. J Am Podiatry Assoc 1982; 72: 436–9.

Topical 2% erythromycin applied twice daily resulted in resolution of PK in both feet within 4 weeks of treatment in one case.

Pitted keratolysis, erythromycin, and hyperhidrosis

Pranteda G, Carlesimo M, Pranteda G, Abruzzese C, Grimaldi M, De Micco S, et al. Dermatol Ther 2014; 27: 101–4.

Erythromycin 3% gel was applied twice daily in an uncontrolled study on 97 patients. Clinical manifestations regressed within 10 days.

Painful, plaque-like, pitted keratolysis occurring in childhood

Shah AS, Kamino H, Prose NS. Pediatr Dermatol 1992; 9: 251–4.

Two children were reported with these lesions; treatment with topical 2% erythromycin solution twice a day was curative in both patients within 3 weeks of commencing treatment.

Ultrastructure of pitted keratolysis

De Almeida Jr HL, De Castro LAS, Rocha NEM, Abrantes VL. Int J Dermatol 2000; 39: 698–709.

A case report of a patient who responded to topical erythromycin with good results.

Coexistent erythrasma, trichomycosis axillaris, and pitted keratolysis: an overlooked corynebacterial triad?

Shelley WB, Shelley ED. J Am Acad Dermatol 1982; 7: 752–7.

A case report of two patients with this triad, one of whom was treated with oral erythromycin 250 mg four times daily and a solution of 20% aluminum chloride applied nightly to the soles. Three weeks later the plantar hyperhidrosis and odor were significantly reduced,

but the pits remained. The other patient declined treatment for PK.

Pitted and ringed keratolysis. A review and update

Zaias N. J Am Acad Dermatol 1982; 7: 787–91.

The author has personal observations (noncontrolled) that treatment of PK with topical clotrimazole, miconazole, erythromycin, tetracycline, clindamycin, glutaraldehyde, formaldehyde, and oral erythromycin are curative. Penicillin has not been useful.

Formaldehyde treatment for pitted keratolysis

Primary Care Dermatologic Society website.

<http://www.pcids.org.uk/patient-information-leaflets> (accessed March 2016).

Patient information leaflet: 5% formaldehyde soaks for 10 minutes daily for 4 to 6 weeks for the treatment of PK.

Third-Line Therapies

• Topical glutaraldehyde	D
• Topical gentamicin	E
• Topical Whitfield ointment	E
• Topical triamcinolone	E
• Topical iodochlorhydroxyquin–hydrocortisone	E
• Topical flexible collodion	E
• Botulinum toxin injections	E

Pitted keratolysis: forme fruste old treatments

Gordon HH. Arch Dermatol 1981; 117: 608.

Buffered glutaraldehyde 2% used with beneficial therapeutic results on PK and hyperhidrosis (uncontrolled personal observations). The author also advises that proper instructions on foot hygiene be given and sandals worn as much as possible. He reports

sensitization to glutaraldehyde in some cases.

Pitted keratolysis: forme fruste. A review and new therapies

Gordon HH. *Cutis* 1975; 15: 54–8.

Buffered glutaraldehyde 2% applied twice daily in five patients resulted in relief of signs and symptoms except in one patient addicted to wearing boots, who continued to have hyperhidrosis. Treatment with gentamicin cream resulted in improvement.

Hyperhidrosis: treatment with glutaraldehyde

Gordon HH. *Cutis* 1972; 9: 375–8.

Eight patients with a mixture of palmar and plantar hyperhidrosis were treated with varying strengths of 2%, 2.5%, 5%, and 10% aqueous glutaraldehyde with good results. Glutaraldehyde 10%, not alkalinized, was found to be rapidly effective but was associated with brown staining. Use of a 5% starting strength three times weekly minimized the tanning, and these patients were then placed on 2% or 2.5% strengths as required for maintenance treatment. None of these patients developed contact dermatitis.

Glutaraldehyde solution

Shah MK. *Indian J Dermatol Venereol Leprol* 2004; 70: 319–20.

Sometimes the patient with PK may require 10% glutaraldehyde to treat the hyperhidrosis. The 10% strength is likely to result in brown staining. Buffering with sodium bicarbonate may reduce the irritation but may also reduce its efficacy and stability. Glutaraldehyde 10% is prepared by mixing 15 mL of water with 10 mL of 25% glutaraldehyde. To buffer to pH 7.5, 1.65 g of sodium bicarbonate is added to 100 mL of 10% glutaraldehyde solution. The buffered solution should be used within half an hour. The author recommends thrice-weekly applications for 2 weeks then once weekly as needed.

Keratolysis plantare sulcatum

Higashi N. *Jpn J Clin Dermatol* 1972; 26: 321–5.

Two patients with KP were treated with topical gentamicin sulfate cream and reported to have good results.

Symptomatic pitted keratolysis

Lamberg SI. *Arch Dermatol* 1969; 100: 10–11.

Report of 12 military personnel with symptomatic PK treated with

various topical agents. One foot was used for treatment, and the other was utilized as a control without treatment or compared with another topical agent. These included steroid creams, antibiotic creams, iodochlorhydroxyquin–hydrocortisone (vioform hydrocortisone) cream, flexible collodion, Whitfield ointment, and formalin in Aquaphor (20–40%). Formalin (40%) ointment appeared to be the most effective and was used for the remainder of both asymptomatic and symptomatic patients with PK. All cases returned to full duty with the ointment after a single outpatient visit, and on reexamination the PK had resolved.

Pitted keratolysis

Gill KA Jr, Buckels LJ. Arch Dermatol 1968; 98: 7–11.

Water-repellent *silicone ointment* has no effect on PK. Lesions resolved spontaneously without treatment after removal from the moist environment.

Plantar hyperhidrosis and pitted keratolysis treated with botulinum toxin injection

Tamura BM, Cucé LC, Souza RL, Levites J. Dermatol Surg 2004; 30: 1510–4.

Two patients resistant to topical and systemic treatments responded completely to one course of low-dose botulinum toxin injections to the plantar aspects of the feet.

Pityriasis rubra pilaris

Anne-Marie Tobin, Brian Kirby, and Mark Lebwohl

Pityriasis rubra pilaris (PRP) is a rare papulosquamous disorder characterized by erythroderma, orange-red keratoderma, and “islands of sparing.” It can be divided into six subtypes based on morphologic phenotype, age of onset, and presence of HIV infection:

- Type I: classical adult; rapid-onset erythroderma, scale, and keratoderma in a craniocaudal pattern
- Type II: atypical adult pattern
- Type III: classical juvenile pattern
- Type IV: atypical juvenile pattern

- Type V: well-circumscribed pattern
- Type VI: HIV-associated PRP

More than 50% of cases are of the classical type I adult-onset PRP. The majority of cases of type I classical PRP go into spontaneous remission after 1 to 3 years.

As PRP is a rare condition, there are no randomized controlled trials assessing treatment efficacy. Treatment recommendations are based on case reports and small case series. PRP has been reported in association with malignancies, including cholangiocarcinoma, metastatic squamous cell carcinoma, colon cancer, and adenocarcinoma of the lung. It is unclear if these are simply chance associations or if they have a role in the development of PRP. There are reports of familial PRP, including rare autosomal-dominant forms of the disease. CARD14 mutations have been reported in familial and sporadic forms of PRP.

Development of PRP after Epstein-Barr virus (EBV) infection has been reported, and antiretroviral therapy has resulted in improvement of type VI PRP. Multiple drugs have also been associated with the development of PRP, including insulin, bevacizumab, sofosbuvir, imatinib, and ponatinib. PRP has also been reported after photodynamic therapy and after treatment with infliximab, a drug that has also been used to treat PRP. There is one report of PRP developing after exposure to dolomite. These reports have been inconsistent and suggest a chance occurrence rather than a true association.

Management Strategy

Topical therapies are primarily used as antipruritic agents. *Emollient* use should be encouraged in combination with emollient baths.

Topical steroids may reduce pruritus but are often ineffective.

There are a few case reports of effective use of both *narrowband UVB* and *PUVA* for PRP. PRP can often be exacerbated by UV light, and we recommend that narrowband UVB and PUVA be only used cautiously and only when other treatments are contraindicated.

Oral retinoids have been the mainstay of therapy for classical type I and type III PRP. Doses of 0.5 mg/kg and upward of *acitretin* are required for adequate control. This often results in significant mucocutaneous side effects and hair loss. Skin fragility and pruritus are common side effects at these doses. It is our practice to initiate

treatment with acitretin for rapid improvement but to add in a second agent if intolerable side effects ensue or if the response is inadequate. Recently a new retinoid, *alitretinoin*, has been used effectively to treat PRP, and it has fewer side effects.

Methotrexate has been reported in several case series as being effective in classical type I PRP. The long-term efficacy of methotrexate is well established. Doses of up to 30 mg weekly are necessary, and concomitant folic acid is recommended. Despite reservations of its use with acitretin regarding hepatotoxicity, it has been reported as a safe combination, and we would concur with that view.

Due to its similarity to psoriasis, PRP has been treated with *TNF- α inhibitors*, *ustekinumab*, *secukinumab*, and *apremilast*. When monotherapy doesn't work, combination therapy can be effective.

Specific Investigations

- Histology
- HIV testing
- Flow cytometry
- Chemistry screen and complete blood count (CBC)

Histology of the affected skin may be useful in aiding the diagnosis. It is important to obtain histology and flow cytometry to rule out other causes of erythroderma, especially cutaneous T-cell lymphoma.

Routine blood tests are recommended as markers of general health and as screening for the use of systemic agents. An HIV test should be done in all patients.

First-Line Therapies

• Retinoids	D
• Methotrexate	D

Late onset pityriasis rubra pilaris type IV treated with low-dose acitretin

Mota F, Carvalho S, Sanches M, Selores M. Acta Dermatovenereol Alp Pannonica Adriat 2016; 25: 15–7.

A 19-year-old with PRP cleared completely after acitretin 25 mg orally every other day for 6 months.

This and other publications advocate acitretin in doses of 0.5 to 0.75 mg/kg daily for PRP.

Alitretinoin (9-*cis* retinoic acid) is effective against pityriasis rubra pilaris: a retrospective clinical study

Amann PM, Susic M, Glüder F, Berger H, Krapf W, Löffler H. Acta Derm Venereol 2015; 95: 329–31.

Four of five patients with PRP responded to oral alitretinoin 30 mg daily for up to 22 weeks.

Where it is available, alitretinoin may be a good alternative retinoid to acitretin because it has fewer mucocutaneous side effects.

Pityriasis rubra pilaris

Griffiths WAD. Clin Exp Dermatol 1980; 5: 105–12.

Methotrexate treatment of PRP is discussed in these papers. In one series, methotrexate was effective in 17 of 42 patients only. This was a retrospective report where various doses and dosing regimens were used. It is the authors' view that doses up to 30 mg weekly may be needed for control.

Second-Line Therapies

• Ciclosporin	E
• TNF- α inhibitors	D
• Ustekinumab	E
• Secukinumab	E
• Apremilast	E

Three cases of pityriasis rubra pilaris successfully treated with cyclosporin A

Usuki K, Sekiyama M, Shimada T, Shimada S, Kanzaki T.
Dermatology 2000; 200: 324–7.

Three cases were successfully treated with 5 mg/kg daily and responded in 3 to 4 weeks. The ciclosporin dose was then gradually tapered.

Some patients require long-term low-dose ciclosporin to maintain remission. Because of the nephrotoxicity of ciclosporin and the malignancies associated with long-term use, switching to alternative therapies should be attempted.

Effectiveness of infliximab in pityriasis rubra pilaris is associated with pro-inflammatory cytokine inhibition

Adnot-Desanlis L, Antonicelli F, Tabary T, Bernard P, Reguiaï Z.
Dermatology 2013; 226: 41–6.

Etanercept-induced clinical remission of type II pityriasis rubra pilaris with rheumatoid arthritis

Kim JH, Park MC, Kim SC. Acta Derm Venereol 2012; 92: 399–400.

Clinical remission of pityriasis rubra pilaris with adalimumab in an adolescent patient

Kim BR, Chae JB, Park JT, Byun SY, Youn SW. J Dermatol 2015; 42: 1122–3.

A systematic review of the literature on the treatment of pityriasis rubra pilaris type I with TNF-alpha antagonists

Petrof G, Almaani N, Archer CB, Griffiths WA, Smith CH. J Eur Acad Dermatol Venereol 2013; 27: e131–5.

Successful treatment of pityriasis rubra pilaris (type 1) under combination of infliximab and methotrexate

Barth D, Harth W, Treudler R, Simon JC. J Dtsch Dermatol 2009; 7: 1071–4.

Eighty-three percent of 15 patients achieved a complete response. In most of these cases the remission achieved was attributable to TNF inhibition. The majority of patients who have been treated with TNF inhibitors have type I classic adult PRP.

The same doses of TNF blockers used for psoriasis have been effective for PRP: etanercept at doses of 25 mg administered subcutaneously twice weekly or 50 mg one to two times per week; subcutaneous adalimumab 80 mg followed by 40 mg every other week; and infusions of infliximab at doses of 5 mg per kg at weeks 0, 2, and 6 and every 6 to 8 weeks thereafter. Clearing occurs in weeks to months, but the condition can recur upon discontinuation of the drug.

Long-term ustekinumab treatment for refractory type I pityriasis rubra pilaris

Di Stefani A, Galluzzo M, Talamonti M, Chiricozzi A, Costanzo A, Chimenti S. J Dermatol Case Rep 2013; 7: 5–9.

A patient with PRP refractory to acitretin, methotrexate, and ciclosporin responded within 4 weeks of his first injection of ustekinumab 45 mg. He achieved complete remission after the third injection and maintained remission on treatment through 64 weeks.

Ustekinumab in psoriasis doses (i.e., 45 mg under 100 kg and 90 mg over 100 kg) at weeks 0 and 4 and every 12 weeks thereafter has been used successfully for PRP in several case reports.

Successful treatment of refractory pityriasis rubra pilaris with secukinumab

Schuster D, Pfister-Wartha A, Bruckner-Tuderman L, Schempp CM. JAMA Dermatol 2016; 152: 1278–80.

A patient with PRP refractory to acitretin responded to secukinumab in the same dose as is used for psoriasis: 300 mg subcutaneously weekly for 5 weeks followed by 300 mg per month. Response was noted in 3 weeks and complete clearing by 8 weeks.

Treatment of refractory pityriasis rubra pilaris with novel phosphodiesterase 4 (pde4) inhibitor apremilast

Krase IZ, Cavanaugh K, Curiel-Lewandrowski C. JAMA Dermatol 2016; 152: 348–50.

A 70-year-old male with PRP developed small cell lymphocytic leukemia shortly after starting infliximab for the PRP. He later responded to apremilast starting at 10 mg per day increased over 5 days to 30 mg twice daily (as is routine for psoriasis).

Third-Line Therapies

• Acitretin and narrowband UVB	E
• Acitretin and UVA1	E
• Intravenous immunoglobulin	E
• Extracorporeal photochemotherapy	E
• Fumaric acid esters	E
• Anti-retroviral therapy	E
• Vitamin A	E

Pityriasis rubra pilaris treated with acitretin and narrow-band UVB (Re-TL-01)

Kirby B, Watson R. Br J Dermatol 2000; 142: 376–7.

This is a single case report of juvenile classic PRP (type III).

Combination ultraviolet A1 radiation and acitretin therapy as a treatment option for pityriasis rubra pilaris

Herbst RA, Vogelbruch M, Ehnis A, Kapp A, Weiss J. Br J Dermatol 2000; 142: 574–5.

This is a case report of long-wave UVA and retinoid in combination for the treatment of classic type I PRP.

Photoaggravated pityriasis rubra pilaris

Evangelou G, Murdoch SR, Palamaras I, Rhodes LE. Photodermatol Photoimmunol Photomed 2005; 21: 272–4.

PRP may be aggravated by UV light, and these treatments should be considered only when other more effective therapies are ineffective or contraindicated.

Extracorporeal photochemotherapy for the treatment of erythrodermic pityriasis rubra pilaris

Hofer A, Mullegger R, Kerl H. Arch Dermatol 1999; 135: 475–6.

Extracorporeal photochemotherapy for the treatment of exanthemic pityriasis rubra pilaris

Haenssle HA, Bertsch HP, Wolf C, Zutt M. Clin Exp Dermatol 2004; 29: 244–6.

These are single case reports of the efficacy of extracorporeal photochemotherapy in PRP.

Type II adult-onset pityriasis rubra pilaris successfully treated with intravenous immunoglobulin

Kerr AC, Ferguson J. Br J Dermatol 2007; 156: 1055–6.

This is a report of the successful use of IVIG at a dose of 2 g/kg given over 3 days. The dose was repeated every 4 weeks. The patient had failed therapy with anti-TNF agents.

Successful treatment of type I pityriasis rubra pilaris with ustekinumab

Ruiz-Villavarde R, Sanchez-Cano D. Eur J Dermatol 2010; 20: 630–1.

Fumaric acid esters: a new treatment modality for pityriasis rubra pilaris

Coras B, Vogt TH, Ulrich H, Landthaler M, Hohenleutner U. Br J

Dermatol 2005; 152: 388–99.

Despite their widespread use in psoriasis, we can find only one case report of fumaric acid ester use in PRP. This was the successful use of fumaric acid esters in a patient with atypical juvenile (type IV) PRP.

HIV-associated pityriasis rubra pilaris: response to triple anti-retroviral therapy

Gonzalez-Lopez A, Velasco E, Pozo T, Del Vilar A. Br J Dermatol 1999; 140: 931–4.

PRP associated with HIV infection may respond to antiretroviral therapy. The response appears to correlate with a reduction in viral load.

Successful treatment of pityriasis rubra pilaris with oral vitamin A in oil (Chocola A) for an 18-month-old child

Kan Y, Sumikawa Y, Yamashita T. J Dermatol 2015; 42: 1210–1.

An 18-month-old infant with PRP was treated with vitamin A 20,000 units daily without response until the dose was increased to 60,000 units daily. Skin lesions resolved after 2 months on that dose, but recurred 2 weeks after the vitamin A was discontinued. The vitamin A was continued intermittently to control the PRP.

Pityriasis lichenoides chronica

Matthew J. Scorer, and Graham A. Johnston

Pityriasis lichenoides chronica (PLC) typically consists of small erythematous papules, which may be purpuric. These develop a characteristic, shiny, micalike scale attached to the center. They occur predominantly over the trunk and proximal limbs. As the name

implies, PLC may persist for many years, though spontaneous resolution does occur. Patients should be warned that relapse is common and that recurrent courses of therapy may be required.

Anecdotally, PLC was said to run a more benign, self-limiting course in children, but more recently it has been shown that in children it is more likely to run an unremitting course, with greater lesional distribution, more dyspigmentation, and a poorer response to treatment. Some authors argue that there is an overlap with cutaneous lymphoma.

Pityriasis lichenoides chronica: stratification by molecular and phenotypic profile

Crowson AN, Morrison C, Li J. Hum Pathol 2007; 38: 479–90.

A prospective study of 46 patients concluded that PLC is an indolent, cutaneous T-cell dyscrasia with a limited propensity for progression to mycosis fungoides.

Management Strategy

There are few therapeutic trials for this condition, and case series are only small. In many therapeutic trials PLC has been grouped together with pityriasis lichenoides et varioliformis acuta (PLEVA), and management strategies are therefore often similar or interchangeable.

Topical corticosteroids are only reported as effective anecdotally in textbooks rather than in studies. They are often used with *antihistamines* to reduce pruritus, but they are not reported to affect the course of the disease.

The majority of reports describe benefits with *UV therapy*, and therefore either UV alone or *psoralen plus UVA (PUVA)* therapy is recommended for all patients. The response appears to be unpredictable, however, and the total dose required is extremely variable.

Antibiotics appear to be more helpful in children, sometimes used in combination therapy.

For severe or refractory cases *methotrexate*, *photochemotherapy*, and *etanercept* have all been described as effective in small numbers of patients.

For most treatment modalities, patients who have been described as improved have usually had fewer new lesions developing, a

shortened disease course, and a greater time to relapse than untreated patients.

Specific Investigation

- Consider skin biopsy

Although a skin biopsy is usually unnecessary in clinically obvious cases, it may be useful before commencing systemic therapy with more potential adverse effects.

An infective etiology is often suggested, but no pathogen has yet been implicated, though associations with toxoplasmosis, human herpesvirus-8 (HHV8), and parvovirus B19 have been described. These reports tend to come from endemic areas, and so investigation for a triggering infection is unnecessary in cases without evidence of specific infection.

The relationship between toxoplasmosis and pityriasis lichenoides chronica

Nassef NE, Hamman MA. J Egypt Soc Parasitol 1997; 27: 93–9.

Twenty-two patients with PLC and 20 healthy controls were examined clinically and serologically for toxoplasmosis. Three (15%) of the controls had toxoplasmosis, compared with 8 (36%) of the patients with PLC. Five of the latter had subsidence of skin lesions after pyrimethamine and sulfapyrimidine treatment.

Pityriasis lichenoides et varioliformis acuta and pityriasis lichenoides chronica: comparison of lesional T-cell subsets and investigation of viral associations

Kim JE, Yun WJ, Mun SK, Yoon GS, Huh J, Choi JH, et al. J Cutan Pathol 2011; 38: 649–56.

Fifty-one patients with pityriasis lichenoides (not subdivided into PLEVA and PLC) were analyzed. HHV-8 was found in 11 (21%) of affected patients but in none of the 25 controls.

Pityriasis lichenoides: a cytotoxic T-cell-mediated skin disorder. Evidence of human parvovirus B19 DNA in nine cases

Tomasini D, Tomasini CF, Cerri A, Sangalli G, Palmedo G, Hantschke M, et al. J Cutan Pathol 2004; 31: 531–8.

Thirty tissue samples from cases of pityriasis lichenoides (both PLEVA and PLC) underwent molecular investigation for parvovirus B19 DNA, which was present in nine cases (30%).

First-Line Therapies

• Ultraviolet B, Psoralen and UVA	C
• Combined UVA and UVB	D
• PUVA	D

Comparative studies of treatments for pityriasis lichenoides

Gritiyarangsarn P, Pruenglampoo S, Ruangratanarote P. J Dermatol 1987; 14: 258–61.

In this open study 30 patients with pityriasis lichenoides were recruited, although the authors did not specify how many had PLEVA and how many PLC. The first group of 8 were given topical corticosteroid, and half had a partial or complete response. The second group were also given oral tetracycline, and the majority had a partial response. The third group of 8 chronic refractory cases were given oral methoxsalen 0.6 mg/kg with UVA three times per week for an average of 2 months; 5 were cleared and 2 had a partial response.

Is narrowband ultraviolet B monotherapy effective in the treatment of pityriasis lichenoides?

Park JM, Jwa SW, Song M, Kim HS, Chin HW, Ko HC, et al. Int J Dermatol 2013; 52: 1013–8.

This retrospective study of 70 patients did not separate PLEVA from PLC but reported a 91.9% complete response rate with narrowband ultraviolet B (NB-UVB). This was not significantly different from the response rate to systemic immunosuppressive therapy or a combination of systemic therapy and NB-UVB.

Narrowband UVB (311 nm, TL01) phototherapy for pityriasis lichenoides

Aydogan K, Saricaoglu H, Turan H. Photodermatol Photoimmunol Photomed 2008; 24: 128–33.

TL-01 phototherapy led to clearance in seven out of eight PLC patients (87.5%) with a mean cumulative dose of 18.4 J/cm² after a mean of 45.8 exposures. Relapses occurred in four patients within a mean period of 6 months.

Phototherapy of pityriasis lichenoides

LeVine MJ. Arch Dermatol 1983; 119: 378–80.

PLC in 12 patients cleared completely after an average of 30 treatments of minimally erythemogenic doses of UVA/UVB from fluorescent sunlamps. The average UV dose required was 388 mJ/cm².

Phototherapy for pityriasis lichenoides: our experience

Macias VC, Marques-Pinto G, Cardoso J. Cutan Ocul Toxicol 2013; 32: 124–7.

This retrospective study reports the use of PUVA or UVA combined with UVB in 13 patients (11 with PLC, 2 with PLEVA). Complete response to PUVA was achieved in 5 patients, with partial response in 2. In the UVA/UVB group, 2 patients had complete response, and 2 had partial response. One patient in each treatment group did not have a therapeutic response.

Comparison of the therapeutic effects of narrowband UVB vs. PUVA in patients with pityriasis lichenoides

Farnaghi F, Seirafi H, Ehsani AH, Agdari ME, Noormohammadpour P. J Eur Acad Dermatol Venereol 2011; 25: 913–6.

This was a study of 15 patients (not stated how many were PLC or PLEVA) who were randomized to receive UVB (complete response 7 of 8, partial 1 of 8) or PUVA (complete 5 of 7, partial 2 of 7). The authors state that the difference in response is insignificant and that both options are acceptable.

Second-Line Therapy

• Erythromycin

C

Pityriasis lichenoides: the differences between children and adults

Wahie S, Hiscutt E, Natarajan S, Taylor A. *Br J Dermatol* 2007; 157: 941–5.

In this retrospective study only two of eight children cleared with erythromycin, whereas three out of four adults cleared without relapse. Phototherapy was more effective in both groups.

Pityriasis lichenoides in childhood: a retrospective review of 124 patients

Ersoy-Evans S, Greco MF, Mancini AJ, Subasi N, Paller AS. *J Am Acad Dermatol* 2007; 56: 205–10.

This was a retrospective study of 124 children, of whom 46 had PLC. The median age of onset was 60 months and median duration was 20 months (range 3–132 months). Two thirds of children had at least a partial response to erythromycin.

Childhood pityriasis lichenoides and oral erythromycin

Hapa A, Ersoy-Evans S, Karaduman A. *Pediatr Dermatol* 2012; 29: 719–24.

The records of 24 children (age range 2–14), 15 with PLC, 6 with PLEVA, and 3 overlap started on erythromycin (30–50 mg/kg/day for 1–4 months), were reviewed. Sixty-four percent showed a good response at 1 month, rising to 83% at 3 months. Of 16 patients with follow-up, 3 relapsed (time not given).

Third-Line Therapies

• Methotrexate	E
• Acitretin plus PUVA	E
• UVA1	E
• Topical tacrolimus	E
• Photodynamic therapy	E
• Etanercept	E

Methotrexate treatment of pityriasis lichenoides and lymphomatoid papulosis

Lynch PJ, Saied NK. *Cutis* 1979; 23: 635–6.

Three patients received methotrexate 25 mg/week intramuscularly or orally. All responded within weeks, but two relapsed on cessation of therapy.

Pityriasis lichenoides chronica induced by adalimumab therapy for Crohn's disease: report of 2 cases successfully treated with methotrexate

Said BB, Kanitakis J, Graber I, Nicolas JF, Saurin JC, Berard F. *Inflamm Bowel Dis* 2010; 16: 912–3.

Pityriasis lichenoides chronica induced by infliximab, with response to methotrexate

López-Ferrer A, Puig L, Moreno G, Camps-Fresneda A, Palou J, Alomar A. *Eur J Dermatol* 2010; 20: 511–2.

Adalimumab-induced pityriasis lichenoides chronica that responded well to methotrexate in a patient with psoriasis

Martínez-Peinado C, Galán-Gutiérrez M, Ruiz-Villaverde R, Solorzano-Mariscal R. *Actas Dermosifiliogr* 2016; 107: 167–9.

There are four reported cases of PLC, all thought to have been caused by anti-TNF α therapies, that responded well to methotrexate.

Photochemotherapy for pityriasis lichenoides: 3 cases

Panse I, Bourrat E, Rybojad M, Morel P. *Ann Dermatol Venereol* 2004; 131: 201–3.

One patient with pityriasis lichenoides and two patients with PLEVA unresponsive to other therapies, including topical corticosteroids, antibiotics, and UVB, responded within weeks to acitretin plus PUVA.

Medium-dose ultraviolet A1 therapy for pityriasis lichenoides varioliformis acuta and pityriasis lichenoides chronica

Pinton PC, Capezzera R, Zane C, De Panfilis G. *J Am Acad Dermatol* 2002; 47: 410–4.

Eight patients (five with PLC and three with PLEVA) were treated. Three patients with PLC showed complete clinical and histologic recovery. Two showed partial improvement.

Successful treatment of pityriasis lichenoides with topical tacrolimus

Simon D, Boudny C, Nievergelt H, Simon HU, Braathen LR. *Br J Dermatol* 2004; 150: 1033–5.

Two children with long-lasting refractory PLC were cleared of skin lesions after 14 and 18 weeks of treatment, respectively.

Pityriasis lichenoides chronica: good response to photodynamic therapy

Fernandez-Guarino M, Harto A, Reguero-Callerjas ME, Urrutia S, Jaen P. *Br J Dermatol* 2008; 158: 198–200.

A woman with 15 lesions of PLC had each occluded with methyl aminolevulinic acid for 3 hours followed by a 595-nm pulsed dye laser as a light source (one pulse for each lesion). Lesions cleared after only one treatment.

Etanercept in therapy multiresistant overlapping pityriasis lichenoides

Nikkels AF, Gillard P, Pierard GE. *J Drugs Dermatol* 2008; 7: 990–2.

A 65-year-old woman had a 5-year history of pityriasis lichenoides unhelped by UVB, PUVA, methotrexate, dapsone, and ciclosporin. She was commenced on etanercept with marked improvement in pruritus and inflammation after 2 months and no new lesions after 4 months when treatment was stopped. However, she relapsed after 1 month.

Conflictingly, there are reports of etanercept, infliximab, and adalimumab causing pityriasis lichenoides.

Pityriasis lichenoides et varioliformis acuta

David Veitch, and Graham A. Johnston

Pityriasis lichenoides et varioliformis acuta (PLEVA) is an eruption of small, erythematous papules that become vesicular and hemorrhagic. Some ulcerate and necrose, leaving pitted scars. The name refers to the morphology, not the duration of the condition,

because a significant proportion of cases regress, with or without treatment, only to recur. Patients should be warned that relapse is common and that recurrent courses of therapy may be required. Febrile ulceronecrotic Mucha–Habermann disease is a rare and severe form of PLEVA characterized by an abrupt onset of an ulceronecrotic eruption associated with a high fever and systemic symptoms.

Management Strategy

There are only a handful of controlled trials for this condition, and large series are rare. Unfortunately, in many therapeutic trials PLEVA is often reported together with and alongside pityriasis lichenoides chronica, and management strategies are therefore often similar or interchangeable.

Although a “wait and see” approach is justifiable in infants, children should be given a 6-week course of *high-dose erythromycin*. Tetracycline should not be given because of its effects on dentition.

Topical corticosteroids are only reported anecdotally in textbooks rather than in studies. They are used with *antihistamines* to reduce pruritus but have no reported effect on disease course.

Second-line therapy in children, and possibly first-line in adults, is *UV light* or *psoralen plus ultraviolet A (UVA) (PUVA)*. The only comparative study has shown Psoralen and ultraviolet A (PUVA) to be more effective.

In more extensive or symptomatic disease *low-dose methotrexate* is useful, and *systemic corticosteroids* or *ciclosporin* have also been used.

In Mucha–Habermann disease, given its severe nature, *combination therapy* is often prescribed. Intravenous immunoglobulin (IVIG) has been utilized recently.

Specific Investigation

- Consider skin biopsy

A diagnostic skin biopsy is unnecessary in clinically obvious cases but may be useful to exclude lymphomatoid papulosis or before commencing aggressive systemic therapy. Classically a lichenoid infiltrate is seen in the superficial dermis with parakeratosis in the stratum corneum and keratinocyte necrosis in the epidermis. There

may be red cell extravasation, including trapped red cells in the epidermis, and a lymphocytic infiltration around the dermal vascular plexus and the dermoepidermal junction.

An infective etiology for PLEVA is suggested by reports of clustering of cases, resolution after tonsillectomy, and occurrence in five members of a family. Varicella-zoster virus (VZV) has been isolated from lesional skin, and DNA from VZV has been demonstrated using polymerase chain reaction (PCR) in skin samples of patients with PLEVA. Case reports exist associating PLEVA with parvovirus, adenovirus in the urine, Staphylococci from throat cultures, Epstein–Barr virus, toxoplasmosis, and Human immunodeficiency virus (HIV) therefore investigation for an infective trigger may be useful.

Pityriasis lichenoides in childhood: a retrospective review of 124 patients

Ersoy-Evans S, Greco MF, Mancini AJ, Subaşı N, Paller AS. J Am Acad Dermatol 2007; 56: 205–10.

The clinical similarity between PLEVA and primary varicella infection and the appearance of cases after chickenpox pointed to the possibility of VZV involvement in this disorder.

Is varicella-zoster virus involved in the etiopathogeny of pityriasis lichenoides?

Boralevi F, Cotto E, Baysse L, Jouvencel AC, Léauté-Labrèze C, Taïeb A. J Invest Dermatol 2003; 121: 647–8.

VZV PCR in skin samples was positive in 8/13 cases (61.5%) of histologically confirmed PLEVA.

Pityriasis lichenoides: a cytotoxic T-cell-mediated skin disorder. Evidence of human parvovirus B19 DNA in nine cases

Tomasini D, Tomasini CF, Cerri A, Sangalli G, Palmedo G, Hantschke M, et al. J Cutan Pathol 2004; 31: 531–8.

This study suggested that pityriasis lichenoides is mediated by a cytotoxic T-cell effector population.

The identification of parvovirus B19 DNA in nine cases may be interpreted ambiguously.

Febrile ulceronecrotic Mucha-Habermann disease: proposed diagnostic criteria and therapeutic evaluation

Nofal A, Assaf M, Alakad R, Amer H, Nofal E, Yosef A. Int J Dermatol 2016; 55: 729–38.

The authors propose constant features that must be present to secure a diagnosis of FUMHD (fever, acute onset of generalized ulceronecrotic papules and plaques, rapid and progressive course, histopathology consistent with PLEVA) and variable features that may help avoid missing cases (previous history of PLEVA, mucous membrane involvement, systemic involvement).

First-Line Therapies

• Oral erythromycin	C
• Oral or IV aciclovir	C

Pityriasis lichenoides in childhood: a retrospective review of 124 patients

Ersoy-Evans S, Greco MF, Mancini AJ, Subasi N, Paller AS. J Am Acad Dermatol 2007; 56: 205–10.

This was a retrospective study of 124 children, 71 of whom had PLEVA. The disease was recurrent in 77%. Erythromycin was given to 79.7% of the affected children, and 66.6% of these showed at least a partial response.

Pityriasis lichenoides in children: therapeutic response to erythromycin

Truhan AP, Hebert AA, Esterly NB. J Am Acad Dermatol 1986; 15: 66–70.

In this retrospective uncontrolled study, 11 children aged 2 to 11 years with biopsy-proven PLEVA were given oral erythromycin 200 mg three or four times daily. Nine improved within a month, and 2 to 6 months after stopping the drug there was only one recurrence. One patient improved on an increased dose, and one failed to respond.

Further case reports describe response to roxithromycin and azithromycin.

Second-Line Therapies

• Broadband ultraviolet B (UVB)	C
• Narrowband UVB	D
• PUVA	D
• Acitretin and PUVA	E

Pityriasis lichenoides in children: a long term follow-up of 89 cases

Gelmetti C, Rigoni C, Alessi E, Ermacora E, Berti E, Caputo R. J Am Acad Dermatol 1990; 23: 473–8.

In a retrospective review of 89 cases seen since 1974 the authors did not differentiate between the treatment of PLEVA and that of pityriasis lichenoides chronica (PLC). However, 77 of the children were treated with 4- to 8-week courses of (presumably broadband) UVB phototherapy, which seemed to alleviate symptoms and acute eruptions without modifying the course of the disease. The remaining 12 patients were given oral erythromycin 20 to 40 mg/kg daily for 1 to 2 weeks, and the response was described as “moderately effective.”

Comparative studies of treatment for pityriasis lichenoides

Gritiyarangsarn P, Pruenglampoo S, Ruangratanarote P. J Dermatol 1987; 14: 258–61.

In this open study 30 patients with pityriasis lichenoides were recruited, although the authors did not specify how many had PLEVA and how many PLC. The first group of eight patients were given topical corticosteroid, and half had a partial or complete response. The second group were given corticosteroid plus oral tetracycline, and the majority had a partial response. The third group of eight patients with chronic refractory pityriasis lichenoides were given oral methoxsalen 0.6 mg/kg with UVA three times a week for an average of 2 months; five cleared and two had a partial response.

Narrowband UVB (311 nm, TL01) phototherapy for pityriasis lichenoides

Aydogan K, Saricaoglu H, Turan H. Photoderatol Photoimmunol Photomed 2008; 24: 128–33.

TL01 treatment led to a complete response in 15 out of 23 PLEVA patients with a mean cumulative dose of 23 J/cm² after a mean of 43.4 exposures. There was a partial response in 8 patients (34.8%) with a cumulative dose of 15.6 J/cm² after a mean of 32.3 exposures.

Photochemotherapy for pityriasis lichenoides

Panse I, Bourrat E, Rybojad M, Morel P. Ann Dermatol Venereol 2004; 131: 201–3.

Two patients, aged 6 and 18 years, presented with a 1-month and 3-month history of PLEVA, respectively. They had received different treatments without significant effect: topical corticosteroids, antibiotic, UVB therapy, and dapsone. A combination of acitretin and PUVA was described as dramatically effective within a few weeks.

Third-Line Therapies

• Methotrexate	E
• ciclosporin	E
• Systemic corticosteroids	E
• Intravenous immunoglobulin	E
• Azithromycin and topical tacrolimus	E

Febrile ulceronecrotic Mucha-Habermann disease: two cases with excellent response to methotrexate

Griffith-Bauer K, Leitenberger SL, Krol A. Pediatr Dermatol 2015; 32: 307–8.

Two biopsy-proven cases of this condition in 6- and 7-year-old boys. One was treated with clindamycin and corticosteroids with

minimal benefit. The other was treated with corticosteroids and cefazolin without benefit. Both were then commenced on 7.5 mg/week of methotrexate, leading to clinical improvement within 4 weeks.

Methotrexate treatment in children with febrile ulceronecrotic Mucha-Habermann disease: case report and literature review

Bulur I, Kaya Erdoğan H, Nurhan Saracoglu Z, Arik D. Case Rep Dermatol Med 2015; 357973.

Eleven-year-old male with biopsy-proven Mucha–Habermann disease treated unsuccessfully with 10 days of 32 mg/day methylprednisolone. Marked improvement was seen after 6 weeks of 15 mg/week methotrexate.

Febrile ulceronecrotic Mucha-Habermann disease in a 34-month-old boy: a case report and review of the literature

Perrin BS, Yan AC, Treat JR. Pediatr Dermatol 2012; 29: 53–8.

Thirty-four-month-old boy treated with corticosteroids, IVIG, dapsone, and aciclovir, without complete resolution of disease. He was then commenced on methotrexate 15 mg/week with disease resolution at 6 weeks.

Resistant pityriasis lichenoides et varioliformis acuta in a 3-year-old boy: successful treatment with methotrexate

Lazaridou E, Fotiadou C, Tsorova C, Trachana M, Trigoni A, Patsatsi A, et al. Int J Dermatol 2010; 49: 215–7.

A 3-year-old boy was diagnosed with biopsy-proven PLEVA. The only therapeutic approach that eventually managed to cease the disease evolution was the combination of prednisolone (1 mg/kg for 8 weeks) and methotrexate (5 mg/week for 8 weeks).

Successful therapy of cyclosporin A in pityriasis lichenoides et varioliformis acuta preceded by hand, foot and mouth disease

Lis-Świąty A, Michalska-Bańkowska A, Zielonka-Kucharzewska A, Pyłacz-Gumprecht A. Antivir Ther 2015; 21(3):273–5.

Enteroviral infection complicated by biopsy-proven PLEVA in a 30-year-old woman. Treatment with 3 mg/kg/day cyclosporin A resulted in rapid clinical improvement and discontinuation after 4 weeks.

Successful long-term use of cyclosporin A in HIV-induced

pityriasis lichenoides chronica

Griffiths JK. J AIDS 1998; 18: 396.

A 42-year-old woman with AIDS developed biopsy-proven Pityriasis lichenoides chronica (PLC), which then developed into life-threatening, febrile, ulceronecrotic PLEVA. Treatment with ciclosporin 200 mg daily produced a rapid response, though prolonged maintenance treatment was required. Interestingly, the severity of symptoms appeared to parallel the viral load.

Pityriasis lichenoides et varioliformis acuta: case report and review of the literature

Pereira N, Brinca A, Manuel Brites M, José Julião M, Tellechea O, Gonçalo M. Case Rep Dermatol 2012; 4: 61–5.

A 63-year-old man with biopsy-proven PLEVA was treated with erythromycin (1 g/day) and methylprednisolone (32 mg/day) reduced gradually over 5 months, with a slow but complete response.

Transition of pityriasis lichenoides et varioliformis acuta to febrile ulceronecrotic Mucha–Habermann disease is associated with elevated serum tumor necrosis factor-alpha

Tsianakas A, Hoeger PH. Br J Dermatol 2005; 152: 794–9.

The authors describe a child whose progression from PLEVA to Mucha–Habermann disease was accompanied by a rapid rise in serum tumor necrosis factor (TNF)- α . She was treated successfully with methotrexate.

The authors postulate that therapy with TNF antagonists may be indicated in these cases.

Febrile ulceronecrotic Mucha-Habermann disease: treatment with infliximab and intravenous immunoglobulins and review of the literature

Meziane L, Caudron A, Dhaille F, Jourdan M, Dadban A, Lok C, et al. Dermatology 2012; 225: 344–8.

A 65-year-old woman with a resistant form of Mucha–Habermann disease was treated with the TNF-alpha inhibitor infliximab (5 mg/kg 6 weekly). However, despite every 6 weeks for 12 months of treatment the patient began to develop new lesions, and treatment became complicated by severe sepsis. The introduction of IVIG (2 mg/kg monthly) induced improvement after “several” months.

High dose immunoglobulins and extracorporeal photochemotherapy in the treatment of febrile ulceronecrotic Mucha–Habermann disease

Marenco F, Fava MT, Quaglino P, Bernengo G. *Dermatol Ther* 2010; 23: 419–22.

A 23-year-old man responded to IVIG (400 mg/kg/day for 5 days monthly) plus methotrexate 10 mg/m² weekly with remission after five courses. He was then started on extracorporeal chemotherapy as maintenance treatment.

Successful association in the treatment of pityriasis lichenoides et varioliformis acuta

Di Constanzo L, Balato N, La Bella S, Balato A. *J Eur Acad Dermatol Venereol* 2009; 23: 971–2.

A 9-year-old girl who failed on oral erythromycin showed “significant improvement” on oral azithromycin 500 mg/day for 3 consecutive days on alternate weeks and daily topical tacrolimus 0.1% ointment. Total duration of treatment was not stated, but there was no recurrence at 4 months.

Pityriasis rosea

Anna E. Muncaster

Pityriasis rosea is a common, acute, self-limiting, papulosquamous disorder affecting the trunk and limbs. It is usually seen in the 10- to 35-year age group and has a recorded incidence of between 0.39% and 4.8% in dermatology patients. It has a classical clinical appearance and is associated with little or no constitutional upset, but can have associated itching. Secondary syphilis and drug eruptions are diagnostic pitfalls.

Management Strategy

Pityriasis rosea usually resolves spontaneously after approximately 6 weeks, and, if asymptomatic, reassurance is all that is required.

Epidemiologic and microbiologic studies have strongly suggested an infectious etiology, most likely viral. The most likely culprits are human herpesvirus-6 (HHV-6) and -7, and in fact reactivation of latent HHV-6 or -7 is postulated but as yet there is no definite proof of causality. Studies have also looked at, but failed to prove, an etiologic role for HHV-8, and there have been two case reports of a pityriasis rosea-like eruption occurring in patients with H1N1 influenza A virus. There have been case reports of pityriasis rosea-like eruptions after many drugs, including captopril, ketotifen, and more recently adalimumab, imatinib mesylate, and etanercept. However, there is no evidence that true pityriasis rosea is drug induced.

For patients who do require treatment, *topical corticosteroids* may be helpful, although evidence for this is purely anecdotal. *Emollients* and oral *antihistamines* have also been mentioned as being of some benefit, as has *ultraviolet light*.

Studies have shown that UVB can reduce itch and disease severity, and a study using low-dose UVA1 phototherapy showed significant reduction in the severity and extent of the disease but little impact on pruritus.

For patients with more extensive severe eruptions, *oral prednisolone* can be tried; however, this should be used with caution, as there are also reports that oral steroids can exacerbate the condition.

A trial of *oral erythromycin* produced complete clearance after 2 weeks in the majority of patients. The best results with all the treatments noted earlier have been obtained when treatment is started within the first 2 weeks of the appearance of the eruption. There has been one case report of vesicular pityriasis rosea responding to 10 days of oral erythromycin at a dose of 250 mg four times a day, but further trials using oral erythromycin, azithromycin, and clarithromycin have all failed to show any benefit.

Oral *acyclovir* has been used in pityriasis rosea at both high and low doses with positive results. One study compared high-dose acyclovir with erythromycin and found acyclovir to be more effective. There has also been one case report of pityriasis rosea clearing after oral acyclovir and one showing clearance with dapsone.

Specific Investigations

- Consider mycologic examination

- Consider syphilis serology

First-Line Therapies

• Topical corticosteroids	E
• Emollients	E
• Oral antihistamines	E

Pityriasis rosea update: 1986

Parsons JM. J Am Acad Dermatol 1986; 15: 159–67.

The author relates his own experience of using topical corticosteroids, emollients, and oral antihistamines in the treatment of pityriasis rosea. He claims all three treatments to have been of some benefit.

A comprehensive review article.

Interventions for pityriasis rosea

Chuh AAT, Dofitas BL, Comisel CG, Reveiz L, Sharma V, Garner SE, et al. Cochrane Database Syst Rev 2007; 2: CD005068.

The authors found that good evidence for the efficacy of most treatments for pityriasis rosea was lacking and suggest more research is needed to fully evaluate erythromycin and other treatments.

Second-Line Therapies

• UVB	B
• UVA1	C

Treatment of pityriasis rosea with UV radiation

Arndt KA, Paul BS, Stern RS, Parrish JA. Arch Dermatol 1983; 119: 381–2.

Twenty patients with symptomatic and extensive pityriasis rosea were treated with UVB phototherapy in a bilateral comparison study using the left side of their body as a control. Five consecutive daily erythemogenic exposures resulted in both clinical and subjective improvement in disease severity and pruritus in 50% of the patients.

UVB phototherapy for pityriasis rosea: a bilateral comparison study

Leenitaphong V, Jiamton S. J Am Acad Dermatol 1995; 33: 996–9.

Seventeen patients with extensive pityriasis rosea were treated unilaterally with 10 daily erythemogenic doses of UVB in a bilateral comparison study using 1 J of UVA to the other half of the body as a control. This resulted in a significant reduction in disease severity in 15 out of the 17 patients but no difference in pruritus.

UVB phototherapy for pityriasis rosea

Valkova S, Trashlieva M, Christova PJ. Eur Acad Dermatol Venereol 2004; 18: 111–2.

In a letter to the editor the authors describe a study of 101 patients (including children) who received broadband UVB either to half the body (24 patients), using UVA on the other half as a control, or to the whole body (77 patients). They showed clearance of the disease in both groups, with those patients having more severe disease requiring significantly more treatments.

Low-dose ultraviolet A1 phototherapy for treating pityriasis rosea

Lim SH, Kim SM, Oh BH, Ko JH, Lee YW, Choe YB, et al. Ann Dermatol 2009; 21: 230–6.

Fifteen patients were treated with UVA1 starting at doses of 10 to 20 J/cm² using 20% increments up to 30 J/cm² given two to three times a week until complete clearance was achieved. Twelve out of the 15 patients showed complete clearance, and the other 3 showed significant improvement with less than 25% of lesions persisting. The mean number of treatments was 6.5.

Third-Line Therapies

• Oral prednisolone	D
• Oral erythromycin	B
• Oral acyclovir	A
• Dapsone	E

One year review of pityriasis rosea at the National Skin Centre, Singapore

Tay YK, Goh CL. Ann Acad Med Singapore 1999; 28: 829–31.

In this retrospective case note study of 368 patients, 20 with extensive pruritic disease were treated with short reducing courses of prednisolone over 2 to 3 weeks, with improvement.

Pityriasis rosea: exacerbation with corticosteroid treatment

Leonforte JF. Dermatologica 1981; 163: 480–1.

This was a case series of 18 patients, all of whom had received oral

corticosteroids for pityriasis rosea. Five were observed while they received their corticosteroid course, and the other 13 were seen after completing their course. In those patients who did report an exacerbation, this was worse the higher the dose of corticosteroid received, the longer the course of treatment, and in those who were treated earlier on in their disease.

Erythromycin in pityriasis rosea: a double-blind, placebo-controlled clinical trial

Sharma PK, Yadav TP, Gautam RK, Taneja N, Satyanarayana L. J Am Acad Dermatol 2000; 42: 241–4.

Ninety patients, including children, were randomly assigned to a treatment or a control group. Those in the treatment group received 2 weeks of oral erythromycin 250 mg four times a day for adults or 25 to 40 mg/kg in four divided doses for children. Of patients in the treatment group, 73% had a complete response compared with none of the controls.

Vesicular pityriasis rosea: response to erythromycin treatment

Miranda SB, Lupi O, Lucas E. J Eur Acad Dermatol Venereol 2004; 18: 622–5.

A case report of a 32-year-old woman with a 6-week history of biopsy-proven vesicular pityriasis rosea who achieved almost complete clearance after 10 days of oral erythromycin at a dose of 250 mg four times a day. No recurrence was observed during a 4-month follow-up period.

The comparison between the efficacy of high dose acyclovir and erythromycin on the period and signs of pityriasis rosea

Eshani A, Esmaily N, Noormohammadpour P, Toosi S, Hosseinpour A, Hosseini M, et al. Indian J Dermatol 2010; 55: 246–8.

In this randomized controlled trial 15 patients with pityriasis rosea were treated with erythromycin 400 mg four times a day for 10 days and the other 15 with acyclovir 800 mg five times a day for 10 days. When evaluated at 8 weeks, 13 out of the 15 patients treated with acyclovir had complete response compared with only 6 of the patients on erythromycin, which was statistically significant. No patients achieved complete response within the first 2 weeks.

A randomized, double-blind, placebo-controlled study of efficacy

of oral acyclovir in the treatment of pityriasis rosea

Ganguly S. J Clin Diag Res 2014; 8: YC01–4

In this randomized, double-blind, placebo-controlled trial 38 patients were started on high-dose acyclovir (800 mg five times daily for adults, 20 mg/kg for children four times daily) for 7 days, and 35 were assigned to the placebo group. Results from day 7 and 14 showed a statistically significant response in the treatment group over placebo with 53.33% complete response at day 7 compared with 10% placebo and 86.66% response at day 14 compared with 33.33% in the placebo group

Use of high-dose acyclovir in pityriasis rosea

Drago F, Veccio F, Rebora A. J Am Acad Dermatol 2006; 54: 82–5.

In this placebo-controlled trial, 87 consecutive patients were treated with either oral acyclovir (800 mg five times daily) or placebo for 1 week. At 14 days 78.6% of treated patients achieved complete regression, compared with only 4.4% of the placebo group.

Low dose acyclovir may be an effective treatment against pityriasis rosea: a random investigator-blind clinical trial on 64 patients

Rassai S, Feily A, Sina N, Abtahian SA. J Eur Acad Dermatol Venereal 2011; 25: 24–6.

Sixty-four patients with pityriasis rosea were enrolled in this randomized, comparative, investigator-blinded trial. Patients were randomized to receive acyclovir 400 mg five times a day for 1 week or control. Fifty-four patients completed the study. At the 4-week follow-up 92.8% of patients in the acyclovir group had significant reduction of erythema compared with 61.5% of patients in the control group.

Antivirals for pityriasis rosea

Castanedo-Cazares JP, Lepe V, Moncada B. Photodermatol Photoimmunol Photomed 2004; 20: 110.

In a letter to the editor the authors relate the successful treatment of a case of pityriasis rosea with a short course of oral acyclovir. Dosage and length of treatment were not stated.

Dapsone treatment in a case of vesicular pityriasis rosea

Anderson CR. Lancet 1971; 2: 493.

A case report of a 55-year-old man with histologically proven pityriasis rosea resistant to oral prednisolone responding to dapsone 100 mg twice daily for 1 month.

Polycystic ovary syndrome

Kristina J. Liu, and Rachel V. Reynolds

Polycystic ovary syndrome (PCOS) is a common endocrine disorder affecting 6% to 25% of reproductive-aged women. It is characterized by hyperandrogenism, menstrual irregularities, polycystic ovaries, and metabolic derangement.

Management Strategy

Several diagnostic criteria for PCOS exist, including definitions from the National Institutes of Health (NIH), the Rotterdam criteria, and the Androgen Excess & Polycystic Ovary Syndrome Society.

Polycystic ovary syndrome diagnostic criteria

1990 National Institutes of Health criteria (both criteria required)

- Chronic anovulation
- Clinical and/or biochemical signs of hyperandrogenism

2003 Rotterdam criteria (two out of three criteria required)

- Oligoovulation or anovulation
- Clinical and/or biochemical signs of hyperandrogenism
- Polycystic ovaries by ultrasound and exclusion of other etiologies (congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome)

2009 Androgen Excess and Polycystic Ovary Syndrome Society (both criteria are required)

- Oligoovulation or anovulation or polycystic ovaries
- Clinical and/or biochemical signs of hyperandrogenism

Box adapted from Setji TL, Brown AJ. Polycystic ovary syndrome: update on diagnosis and treatment. Am J Med 2014; 127: 912–9.

Treatment of PCOS is targeted toward decreasing androgen excess, normalizing menses, and ameliorating metabolic syndrome and cardiovascular complications. Although treatment of the reproductive and metabolic complications decreases the risk of endometrial cancer and cardiovascular issues, treatment of cutaneous disease is also integral to the care of these patients and their quality of life.

Cutaneous manifestations resulting from androgen excess may include acne in 25% to 35%, hirsutism in 40% to 92%, female pattern alopecia, seborrhea, and, in some, acanthosis nigricans, a sign of hyperinsulinemia. Therefore as dermatologists, we are in a unique position to identify and treat patients early in the course of their disease.

Cutaneous manifestations, including acne and hirsutism, may be targeted using topical or oral retinoids and/or topical or systemic antibiotics. If the response is inadequate, combined oral

contraceptives (OCPs) and/or antiandrogen therapy may be beneficial. Mechanical hair removal methods may be utilized. In patients with PCOS, lifestyle modification is the first-line treatment, and weight loss may correct all metabolic abnormalities. In those with inadequate response, insulin resistance may be treated with insulin-sensitizing agents, such as metformin.

PCOS is associated with several mental health problems, including depression and anxiety, body dissatisfaction and eating disorders, diminished sexual satisfaction, and lowered health-related quality of life. Patients should be evaluated for psychological issues and referred for appropriate counseling as needed.

Specific Investigations

- Ovary ultrasound imaging
- Serum androgen levels (testosterone, dehydroepiandrosterone sulfate (DHEA-S), 17-hydroxyprogesterone)
- Pregnancy (urine or serum hCG)
- Other hormone tests (follicle-stimulating hormone (FSH), luteinizing hormone (LH), thyroid stimulating hormone (TSH), prolactin, 24-hour urine free cortisol)
- Metabolic factors, diabetes (body mass index (BMI), fasting lipid panel, oral glucose-tolerance test)
- Blood pressure

Polycystic ovary syndrome: a review for dermatologists. Part I. Diagnosis and manifestations

Housman E, Reynolds RV. J Am Acad Dermatol 2014; 71: 847.e1–e10.

PCOS is a common disorder that affects up to 8% of women of reproductive age. Other etiologies of hyperandrogenism and anovulation should be ruled out before making a diagnosis of PCOS.

Metformin and lifestyle modification in polycystic ovary syndrome: systematic review and meta-analysis

Naderpoor N, Shorakae S, de Courten B, Misso ML, Moran LJ, Teede HJ. Hum Reprod Update 2015; 21: 560–74.

A meta-analysis comparing the effects of lifestyle modification, metformin, or the combination of these two therapies on metabolic, reproductive, anthropometric, and psychological outcomes.

Lifestyle modification together with metformin is associated with improved menstruation and lower BMI in women with PCOS compared with either therapy alone.

Impaired glucose tolerance, type 2 diabetes and metabolic syndrome in polycystic ovary syndrome: a systematic review and meta-analysis

Moran LJ, Misso ML, Wild RA, Norman RJ. Hum Reprod Update 2010; 16: 347–63.

Women with PCOS have increased glucose levels, type 2 diabetes, and metabolic syndrome.

PCOS is strongly linked with insulin resistance and glucose intolerance. Screening for impaired glucose tolerance requires an oral glucose-tolerance test (75 g, 0- and 2-hour values), as HbA_{1c} demonstrates lower sensitivity in comparison.

Meta-analysis of cardiovascular disease risk markers in women with polycystic ovary syndrome

Toulis KA, Goulis DG, Mintziori G, Kintiraki E, Eukarpidis E, Mouratoglou SA, et al. Hum Reprod Update 2011; 17: 741–60.

A meta-analysis of 130 studies revealed that women with PCOS have more coronary artery calcification, vascular endothelial dysfunction, and elevated C-reactive protein and homocysteine levels. Although women with PCOS have increased serum concentrations of cardiovascular disease (CVD) risk markers, an association with increased incidence of CVD is unclear.

Periodic assessment of diabetes, blood pressure, fasting lipid panel, and BMI is recommended in women with PCOS.

Risk of endometrial, ovarian and breast cancer in women with polycystic ovary syndrome: a systematic review and meta-analysis

Barry JA, Azizia MM, Hardiman PJ. Hum Reprod Update 2014; 20: 748–58.

Women of all ages with PCOS are three times more likely to develop endometrial cancer, but there is no evidence of increased risk of breast cancer or ovarian cancer.

First-Line Therapies

• Weight loss	A
• Topical and systemic therapy for acne	A
• Oral contraceptives	A
• Topical eflornithine	B
• IPL (intense pulsed light)/laser hair removal	B
• Minoxidil	B

Lifestyle changes in women with polycystic ovary syndrome

Moran LJ, Hutchison SK, Norman RJ, Teede HJ. Cochrane Database Syst Rev 2001; 7: CD007506.

Lifestyle intervention improves hyperandrogenism (based on clinical hirsutism and total testosterone level), waist circumference, and fasting insulin. Weight management is proposed as an initial treatment strategy.

Treatment of hirsutism and acne in hyperandrogenism

Moggetti P, Toscano V. Best Pract Res Clin Endocrinol Metab 2006; 20: 221–34.

Topical retinoids are the first-line therapy for comedonal acne and may be combined with a topical antibiotic. Azelaic acid demonstrates moderate antibacterial, antiinflammatory, and keratolytic activity. Topical benzoyl peroxide is weakly comedolytic, but is a potent antibiotic. Concomitant use of benzoyl peroxide decreases incidence of antibiotic resistance.

Topical treatments are first-line therapy in acne. In the presence of scarring acne or treatment failure, oral therapy is indicated.

Polycystic ovary syndrome: a review for dermatologists. Part II. Treatment

Buzney E, Sheu J, Buzney C, Reynolds RV. J Am Acad Dermatol 2014; 71: 859.e1–e15.

Combination OCPs are effective for hirsutism, with the addition of spironolactone (starting at 50 mg per day) when appropriate. Topical therapies remain first line for acne, and in patients who fail to respond, addition of combination OCPs are effective. Finasteride and flutamide lack sufficient data for recommendation of their use.

Combination OCPs have demonstrated efficacy for hirsutism and acne in patients with PCOS with low side effect profiles.

Combined oral contraceptive pills for treatment of acne

Arowojolu AO, Gallo MF, Lopez LM, Grimes DA. Cochrane Database Syst Rev 2012; 7: CD004425.

Combined oral contraceptives (COCs) reduced acne lesion counts, severity grades, and self-assessed acne. Those containing chlormadinone acetate or cyproterone acetate (CPA) were more effective than levonorgestrel. Overall, few differences in efficacy were found between the COC types in treatment of acne.

Food and Drug Administration (FDA)–approved OCPs for acne include norgestimate/EE (ethinyl estradiol), norethindrone acetate/EE, and drospirenone/EE.

Hirsutism: an evidence-based treatment update

Somani N, Turvy D. Am J Clin Dermatol 2014; 15: 247–66.

Physical modalities are recommended as first-line treatments, including the use of electrolysis for permanent hair removal and lasers for permanent hair reduction. Other recommended therapies include OCPs and antiandrogens.

Randomized, double-blind clinical evaluation of the efficacy and safety of topical eflornithine HCl 13.9% cream in the treatment of women with facial hair

Wolf JE Jr, Shander D, Huber F, Jackson J, Lin CS, Mathes BM, et al. Int J Dermatol 2007; 46: 94–8.

Topical eflornithine cream, applied twice daily for 24 weeks, significantly reduced hair length and mass.

A randomized controlled trial of laser treatment among hirsute women with polycystic ovary syndrome

Clayton WJ, Lipton M, Elford J, Rustin M, Sherr L. Br J Dermatol 2005; 152: 986–92.

Treatment with alexandrite laser reduced severity of facial hair and

decreased depression and anxiety in patients with PCOS.

Evidence-based treatments for female pattern hair loss: a summary of a Cochrane systematic review

van Zuuren EJ, Fedorowicz Z, Carter B. Br J Dermatol 2012; 167: 995–1010.

Minoxidil induced a moderate increase in hair regrowth in patients with androgenic alopecia.

Second-Line Therapies

• Antiandrogens	B
• Metformin	B

Spironolactone versus placebo or in combination with steroids for hirsutism and/or acne

Brown J, Farquhar C, Lee O, Toomath R, Jepson RG. Cochrane Database Sys Rev 2009; 2: CD000194.

Spironolactone 100 mg daily resulted in subjective decrease in hair growth. There was no evidence for effectiveness in treating acne.

In general, spironolactone is considered the first choice in antiandrogen drugs in the treatment of hirsutism. Lower-grade evidence supports anecdotal efficacy in acne.

Comparison of spironolactone, flutamide, and finasteride efficacy in the treatment of hirsutism: a randomized, double blind, placebo-controlled trial

Moggetti P, Tosi F, Tosti A, Negri C, Misciali C, Perrone F, et al. J Clin Endocrinol Metab 2000; 85: 89–94.

Forty hirsute female subjects were randomized to receive spironolactone 100 mg daily, flutamide 250 mg daily, finasteride 5 mg daily, or placebo. All treatment groups revealed similar reduction in

hair diameter.

Due to high cost and potential adverse liver effects, flutamide is rarely used.

Antiandrogens should not be used without effective contraception, given the potential risk for feminization of a male fetus.

Metformin use in women with polycystic ovary syndrome

Johnson NP. Ann Transl Med 2014; 2: 56.

Metformin improves insulin resistance and anovulatory infertility in women with PCOS.

Limited evidence suggests that metformin may improve hirsutism and acne in PCOS. Five hundred mg three times daily has been suggested in the literature.

Third-Line Therapies

• Pioglitazone	D
• Rosiglitazone	D

Thiazolidinediones for the therapeutic management of polycystic ovary syndrome: impact on metabolic and reproductive abnormalities

Elkind-Hirsch KE. Treat Endocrinol 2006; 5: 171–87.

Convincing data from appropriately powered randomized controlled trials are still needed to determine whether thiazolidinediones are safe and effective in PCOS.

When should an insulin sensitizing agent be used in the treatment of polycystic ovary syndrome?

Frank S. Clin Endocrinol (Oxf) 2011; 74: 148–51.

Metformin has been shown to be safer than other insulin-sensitizing agents.

Polymorphic light eruption

Warwick L. Morison, and Elisabeth G. Richard

Polymorphic light eruption is the most common photodermatosis, with a prevalence of 10% to 20% in temperate climates, particularly among young women. It develops on sun-exposed body parts hours to a day or more after specific exposure to sunlight, usually in spring

or early summer. The morphology varies, with papular or papulovesicular forms being most common, and the rash is always pruritic. Plaques, insect-bite type, and erythema multiforme variants are much less common. In most patients the tendency to develop polymorphic light eruption diminishes with repeated exposures to sunlight, a phenomenon called *hardening*.

Management Strategy

The treatment of polymorphic light eruption consists of two phases: treatment of established disease after the rash has appeared, and the prevention of the rash in patients known to have the disease.

Application of a *midpotency* or *high-potency corticosteroid cream or ointment*, two or three times daily, is usually sufficient to reduce symptoms and clear the rash in most patients with established disease. Use of topical corticosteroids as treatment is based on historical clinical experience rather than formal clinical studies. A few patients with extensive disease and marked symptoms require *oral prednisone* in a dose of 60 to 80 mg for a few days, followed by rapid reduction of the dose over a week.

Preventive management is the best choice for patients diagnosed with the disease. The majority of patients with polymorphic light eruption have high-threshold disease, so they require prolonged exposure to sunlight or artificial sources of ultraviolet (UV) radiation to trigger the reaction. Most of these individuals do not seek medical advice but learn to limit their exposure to levels below their threshold or, in some cases, to prevent the disease by use of sunscreens. Patients seeking medical advice usually have low-threshold disease, often triggered by 15- to 30-minute exposures to sunlight, leading to marked limitation of outdoor activities.

The initial approach to the prevention of polymorphic light eruption is *avoidance of exposure to sunlight* using a combination of reduced time spent outdoors, restriction of exposure to early morning and late afternoon hours, wearing of protective clothing, and application of *broadband sunscreens* that protect against both UVA and UVB wavelengths. This strategy is most likely to be effective in patients with high-threshold disease and those triggered by UVB radiation.

The most effective approach for patients with low-threshold disease is desensitization using a course of *PUVA (psoralen–UVA)*, *narrowband*

(311 nm) UVB phototherapy, or broadband UVB phototherapy in spring, followed by regular exposures to sunlight during summer to maintain tolerance. Photo(chemo)therapy stimulates the hardening phenomenon and aims to induce photoadaptation. This approach is successful in preventing polymorphic light eruption in up to 90% of patients, but requires planning, as treatment lasts for about a month. Patients who develop polymorphic light eruption while on treatment should continue therapy and may require topical or oral corticosteroids to control the rash.

Hydroxychloroquine, β -carotene, *Polypodium leucotomos*, and *nicotinamide* are reported to provide moderate and safe protection in polymorphic light eruption and may be considered in patients unable to undertake, or who are unresponsive to, desensitization therapy. Hydroxychloroquine is sometimes a useful preventive measure during a brief winter vacation in a warm climate. It should be started 3 days before the vacation in a dose of 400 mg daily and continued throughout the vacation.

Specific Investigations

- Skin biopsy
- Phototesting
- Lupus serologies

Marked papillary dermal edema – an unreliable discriminator between polymorphous light eruption and lupus erythematosus or dermatomyositis

Pincus LB, LeBoit PE, Goddard DS, Cho RJ, McCalmont TH. *J Cutan Pathol* 2010; 37: 416–25.

The histologic pattern of this subgroup is characteristic but not pathognomonic.

Clinical and therapeutic aspects of polymorphous light eruption

Dummer R, Ivanova K, Scheidegger EP, Burg G. *Dermatology* 2003; 207: 93–5.

Clinical aspects and photoprovocation testing are reviewed. Narrowband UVB is recommended as the first line for photohardening, with PUVA as second line.

An optimal method for experimental provocation of polymorphic light eruption

van de Pas CB, Hawk JLM, Young A, Walker SL. Arch Dermatol 2004; 140: 286–92.

Solar-simulated radiation was effective in inducing the rash in almost 70% of patients, and there was no difference in success rate between previously affected and previously unaffected skin.

Because 100% of patients have developed polymorphic light eruption from exposure to sunlight or an indoor source of UV radiation such as a suntan parlor, the most reliable method of reproducing the eruption is to request the patient to deliberately expose his or her skin to the source of light that produced his or her rash and to return for inspection and biopsy. Polymorphic light eruption can be induced by UVA and/or UVB.

The prevalence of antinuclear antibodies in patients with apparent polymorphic light eruption

Murphy GM, Hawk JLM. Br J Dermatol 1991; 125: 448–51.

Of 142 patients with a history consistent with polymorphic light eruption, 6% had a positive Ro antibody test or subsequently developed lupus erythematosus. A lupus panel of tests is essential in patients being considered for active desensitization treatment.

First-Line Therapies

• Restriction of sun exposure	E
• Sun screens	A
• Protective clothing	E
• Mid- to high-potency topical corticosteroids	E

A new ecamsule-containing SPF 40 sunscreen cream for the prevention of polymorphous light eruption: a double-blind, randomized, controlled study in maximized outdoor conditions

DeLeo VA, Clark S, Fowler J, Poncet M, Loesche C, Soto P. Cutis 2009; 83: 95–103.

A broad-spectrum sunscreen containing two UVA filters was significantly better at preventing flares of polymorphous light eruption than a similar product containing just one UVA filter.

Textiles and sun protection

Robson J, Diffey BL. Photodermatol Photoimmunol Photomed 1990; 7: 32–4.

Transmission of UV radiation through clothing varies greatly, providing an “SPF” in this study from 2 for a polyester blouse to 1571 for cotton denim jeans. The tightness of the weave is the main variable determining transmission of light. Transmission of UV radiation for all fabrics is increased when a fabric is wet.

Clothing and hats are now available specifically designed to provide protection from sunlight while maintaining a high level of comfort.

Second-Line Therapies

• PUVA therapy	C
• Narrowband (311 nm) phototherapy	C
• Broadband UVB phototherapy	C

UVB phototherapy and photochemotherapy (PUVA) in the treatment of polymorphic light eruption and solar urticaria

Addo HA, Sharma SC. Br J Dermatol 1987; 116: 539–47.

Patients were treated with a regular schedule of oral PUVA or high-dose (erythemogenic) broadband UVB phototherapy three times weekly for 5 weeks during the spring and were then instructed to maximize their exposure to sunlight during summer. Ninety percent of PUVA-treated patients and about 70% of UVB-treated patients were free of symptoms of polymorphic light eruption during the summer. Development of the eruption during the active treatment was common, usually mild, and did not interfere with treatment.

A comparison of narrowband (TL-01) and photochemotherapy

(PUVA) in the management of polymorphic light eruption

Bilsland D, George SA, Gibbs NK, Aitchison T, Johnson BE, Ferguson J. Br J Dermatol 1993; 129: 708–12.

A regular schedule of oral PUVA therapy or narrowband (311 nm) phototherapy was given to patients three times a week for 5 weeks in the spring, resulting in about 85% of patients in each treatment group being adequately protected from developing polymorphic light eruption during the summer. The necessity for regular sun exposure every week during the summer may not have been emphasized.

Third-Line Therapies

• Prednisolone	A
• Hydroxychloroquine	A
• β -Carotene	C
• Nicotinamide	B
• Azathioprine	E
• Ciclosporin	E
• Flavonoid antioxidant	A
• Topical liposomal DNA repair enzymes	A
• <i>Polypodium leucotomos</i>	B
• LED photoprevention	C

Efficacy of short-course oral prednisolone in polymorphic light eruption: a randomized controlled trial

Patel DC, Bellaney GJ, Seed PT, McGregor JM, Hawk JLM. Br J Dermatol 2000; 143: 828–31.

A 7-day course of 25 mg prednisolone daily was superior to

placebo when started at the onset of the rash. This low dose of steroid is suitable for managing patients who are on brief vacations in a sunny climate.

Prednisone would be a suitable alternative.

Hydroxychloroquine in polymorphic light eruption: a controlled trial with drug and visual sensitivity monitoring

Murphy GM, Hawk JLM, Magnus IA. Br J Dermatol 1987; 116: 379–86.

Hydroxychloroquine in a dose of 400 mg daily for 1 month, and 200 mg daily for 2 months, was superior to placebo in preventing development of the rash; however, almost all patients did have a rash and irritation during the trial. The degree of protection was judged to be moderate and was related to serum level of the drug; the dose of 400 mg daily provided better protection. No visual toxicity was observed.

Comparison of PUVA and beta-carotene in the treatment of polymorphous light eruption

Parrish JA, Le Vine MJ, Morison WL, Gonzalez E, Fitzpatrick TB. Br J Dermatol 1979; 100: 187–91.

β-Carotene (3.0 mg/kg) in a twice-daily divided dose given for the entire summer provided full protection for 30% of patients and partial protection for another 20%. There were no adverse effects.

Treatment of polymorphous light eruption with nicotinamide: a pilot study

Neumann R, Rappold E, Pohl-Markl H. Br J Dermatol 1986; 115: 77–80.

Nicotinamide given in a dose of 1 g orally three times daily starting 2 days before sun exposure provided complete protection in 60% of patients. The dose was reduced to 2 g daily after 1 week; about half of these patients developed polymorphic light eruption. A few patients had mild fatigue.

Successful treatment of severe polymorphous light eruption with azathioprine

Norris PG, Hawk JLM. Arch Dermatol 1989; 125: 1377–9.

Two patients with year-round photosensitivity triggered by as little as 1 to 2 minutes of sun exposure and unresponsive to all standard treatments were treated with 0.8 to 2.5 mg/kg of azathioprine daily for

3 months, with complete remission of symptoms and normal sun tolerance.

The erythematous responses to UVB radiation were reduced in both patients and to UVA radiation in one, which is an unusual finding in typical cases of polymorphic light eruption.

Prophylactic short-term use of cyclosporine in refractory polymorphic light eruption

Lasa O, Trebol I, Gardeazabal J, Diaz-Perez JL. J Eur Acad Dermatol Venereol 2004; 18: 747–8.

Ciclosporin in a dose of 3 to 4 mg/kg/day over 2 or 4 weeks was effective in preventing the development of an eruption in three patients during a short vacation in a sunny climate. The patients had not responded to other preventive measures. No adverse effects were observed, and this appears to have promise as a prophylactic treatment in patients resistant to other therapies.

Polymorphous light eruption (PLE) and a new potent antioxidant and UVA-protective formulation as prophylaxis

Hadshiew IM, Treder-Conrad C, Bülow RV, Klette E, Mann T, Stäb F, et al. Photodermatol Photoimmunol Photomed 2004; 20: 200–4.

A flavonoid antioxidant plus a broad-spectrum sunscreen was more effective in preventing PLE than sunscreen alone or placebo.

Topical liposomal DNA-repair enzymes in polymorphic light eruption

Hofer A, Legat FJ, Gruber-Wackernagel A, Quehenberger F, Wolf P. Photochem Photobiol Sci 2011; 10: 1118–28.

After-sun lotion containing liposomal DNA-repair enzymes decreased polymorphous light eruption symptoms. Of note, pretreatment with SPF30 sunscreen prevented polymorphous light eruption in this group of susceptible patients.

Oral administration of a hydrophilic extract of *Polypodium leucotomos* for the prevention of polymorphic light eruption

Tanew A, Radakovic S, Gonzalez S, Venturini M, Calzavara-Pinton P. J Am Acad Dermatol 2012; 66: 58–62.

Photopro provocation tests were administered to 35 polymorphic light eruption patients before and after an open label, 2-week course of *Polypodium leucotomos* 720 mg to 1200 mg daily depending on weight.

Thirty percent of patients with UVA-induced polymorphic light eruption did not respond to the repeat exposure, and 28% of those induced by UVB did not respond to the second exposure. For the remaining patients, significantly more exposure was required to elicit polymorphic light eruption.

This study suggests that pretreatment with Polypodium leucotomos for 2 weeks before sun exposure and during the period of sun exposure may be beneficial.

Photoprotective activity of oral *Polypodium leucotomos* extract in 25 patients with idiopathic photodermatoses

Caccialanza M, Percivalle S, Piccinno R, Brambilla R. Photodermatol Photoimmunol Photomed 2007; 23: 46–7.

Daily oral administration of *Polypodium leucotomos* extract provided improvement in over 40% of patients in terms of tolerance to sun exposure without developing PLE.

LED photoprevention: reduced MED response following multiple LED exposures

Barolet D, Boucher A. Lasers Surg Med 2008; 40: 106–12.

In patients with and without history of PLE, pretreatment with 660 nM light power LED light source reduced redness at all MEDs tested.

Porokeratoses

Agustin Martin-Clavijo, and John Berth-Jones

The porokeratoses are a group of disorders of keratinization characterized by lesions with a peripheral keratotic ridge, manifesting histologically as a cornoid lamella. Terminology and classification are debated, but the main recognized forms are (1) disseminated forms, of which disseminated superficial actinic porokeratosis (DSAP) is predominant; (2) porokeratosis of Mibelli (PM); (3) palmoplantar porokeratosis (porokeratosis palmaris, plantaris et disseminata – PPPD); and (4) linear porokeratosis (LP). An autosomal-dominant mode of inheritance has been reported in the disseminated form,

which is not always “actinic” in origin. Overexpression of the p53 tumor suppression protein has been identified in the cornoid lamella. Porokeratotic lesions are progressive and carry malignant potential, especially large long-standing lesions and the linear variants. In addition, the lesions can cause pruritus and represent a cosmetic problem for some patients.

Management Strategy

The family history should be reviewed and the patient’s immune function assessed, particularly with the disseminated forms. Discontinuation of immunosuppression has led to resolution of lesions in some patients.

The lesions are usually asymptomatic, but may be pruritic, and the palmoplantar variant may cause functional disability due to pain and discomfort.

Treatment is not always required, but may be indicated, not only for cosmetic benefit and symptomatic relief but also to reduce the risk of malignancy. Optimal therapy therefore depends on the type and extent of porokeratosis and the level of concern over malignant progression. Management should include avoidance of irradiation (UV or x-rays) and observation for signs of malignant transformation (squamous cell carcinoma, basal cell carcinoma, Bowen disease).

When present, pruritus associated with disseminated lesions is often responsive to *topical corticosteroids*. Localized disease responds to “surgical” methods such as *cryotherapy*, *CO₂ laser*, *curettage and cautery*, or *excision*, but these can result in significant scarring, especially when the lesions are numerous.

Topical 5-fluorouracil, *imiquimod*, and *vitamin D analogs* can be helpful, but only partial responses are likely in DSAP. Inflammatory reactions are likely when using 5-fluorouracil or imiquimod and indicate a greater likelihood of response. With some caution, these modalities can be used under occlusion, treating one area at a time. In the authors’ experience results are inconsistent, even with occlusion.

Systemic retinoids have been effective in localized and systemic disease, but there have been reports of exacerbation of preexisting lesions. Recurrence is common on discontinuation of therapy, and a long-term maintenance dose may be required. This modality might also reduce the risk of malignant transformation.

A recent report of the use of topical ingenol mebutate may prove to be an advance if the results are found to be consistent.

There is one report of genital DSAP responding partially to *topical diclofenac*, but a subsequent case series demonstrated very limited benefit. There are also reports of the effectiveness of *topical retinoids*, *dermabrasion*, *various lasers and IPL*, *corticosteroids*, and *topical photodynamic therapy*. Treatments used in combination have included *CO₂ laser and tacalcitol*, *CO₂ laser and photodynamic therapy*, *5-fluorouracil and imiquimod*, and *calcipotriol with adapalene*.

Specific Investigations

- Biopsy
- Dermoscopy
- Assessment of immune function

Dermoscopy for the diagnosis of porokeratosis

Delfino M, Argenziano G, Nino M. J Eur Acad Dermatol Venereol 2004; 18: 194–5.

Dermoscopic examination of DSAP showed a characteristic central scarlike area with a single or double “white track” structure at the margin. The histopathologic correlate of the linear structure was shown to be the cornoid lamella.

First-Line Therapy

- | | |
|---------------|---|
| • Cryotherapy | D |
|---------------|---|

Porokeratosis of Mibelli: successful treatment with cryosurgery

Dereli T, Ozyurt S, Osturk G. J Dermatol 2004; 31: 223–7.

Eight patients with 20 lesions received treatment with 30-second cycles of cryospray followed by sharp dissection of the lesion border. Most lesions resolved after one treatment; two required one further

treatment.

Cryosurgery of porokeratosis plantaris discreta

Limmer BL. Arch Dermatol 1979; 115: 582–3.

Twenty-one lesions of porokeratosis in 11 patients were treated with cryotherapy, resulting in a cure rate of 90.5%. The lesions were pared before treatment. There was no evidence of recurrence over an average follow-up period of 22 months.

Second-Line Therapies

• 5-Fluorouracil	D
• Imiquimod	E
• Vitamin D analogs	E

Fluorouracil ointment treatment of porokeratosis of Mibelli

Gonçalves JC. Arch Dermatol 1973; 108: 131–2.

Six patients with facial lesions were treated with 5% fluorouracil ointment three times daily. The treatment was maintained for 8 to 10 days after a strong inflammatory response occurred. There was no recurrence at 9-month follow-up.

Disseminated superficial porokeratosis: rapid therapeutic response to 5-fluorouracil

Shelley WB, Shelley ED. Cutis 1983; 32: 139–40.

Resolution of porokeratosis was observed after 3 weeks of daily application of 5% 5-fluorouracil cream. There was no recurrence at 5-month follow-up.

Porokeratosis of Mibelli: successful treatment with 5% imiquimod cream

Agarwal S, Berth-Jones J. Br J Dermatol 2002; 146: 338–9.

A 3-cm lesion of PM on the leg was initially treated with topical imiquimod 5% cream five times a week for 3 months, with no improvement. Subsequent treatment with imiquimod 5% cream five times a week under occlusion with an adhesive polythene dressing was successful. There was no recurrence at 1 year.

Disseminated superficial actinic porokeratosis treated effectively with topical imiquimod 5% cream

Arun B, Pearson J, Chalmers R. Clin Exp Dermatol 2011; 3: 509–11.

One patient with DSAP responded to imiquimod 5% cream five times a week for 6 weeks.

Disseminated superficial actinic porokeratosis: treatment with topical tacalcitol

Bohm M, Luger TA, Bonsmann G. J Am Acad Dermatol 1999; 40: 479–80.

DSAP responded to 5 months of topical daily treatment with 0.0004% tacalcitol and remained clear on alternate-day maintenance therapy.

Disseminated superficial actinic porokeratosis responding to calcipotriol

Harrison PV, Stollery N. Clin Exp Dermatol 1994; 19: 95.

Three patients were treated with topical calcipotriol daily for 6 to 8 weeks. An overall improvement of 50% to 75% was noted and maintained for up to 6 months in two patients.

Third-Line Therapies

• Systemic retinoids	D
• Topical retinoids	E
• CO ₂ laser	D
• Nd:YAG laser	E
• Pulsed dye laser	E
• Ruby laser	E
• Fractional photothermolysis	E
• Intense pulse light (IPL)	D
• Photodynamic therapy	E
• Dermabrasion	E
• Fluor-hydroxy pulse peel	E
• Corticosteroids	E
• Diclofenac 3% gel	C
• Ingenol mebutate	E
• 5-Fluorouracil with imiquimod cream	E
• Photodynamic therapy with CO ₂ laser	E
• Excision and skin graft	E
• Ciclosporin (for intense pruritus)	E
• Cantharidin	E

Generalized linear porokeratosis: a rare entity with excellent response to acitretin

Garg T, Ramchander Varghese B, Barara M, Nangia A. *Dermatol Online J* 2011; 17: 3.

A patient with generalized LP was treated with acitretin 0.5 mg/kg. There was marked flattening of the lesions after 6 weeks but not complete resolution after 5 months of treatment.

Disseminated porokeratosis Mibelli treated with Ro 10-9359

Bundino S, Zina AM. *Dermatologica* 1980; 160: 328–36.

Two patients with DSAP were treated with 50 to 75 mg daily of etretinate, with significant clinical improvement after 5 weeks; 25 mg daily was sufficient to maintain the results. Recurrence was observed 3 to 4 weeks after cessation of treatment.

Treatment of disseminated superficial actinic porokeratosis with a new aromatic retinoid (Ro 10-9359)

Kariniemi A, Stubb S, Lassus A. *Br J Dermatol* 1980; 102: 213–4.

Treatment with 50 to 100 mg daily of etretinate led to significant clinical improvement and resolution of pruritus within 40 days. A dose of 25 mg on alternate days was required to maintain the results. After 6 months of treatment the patient developed follicular hyperkeratosis with tiny keratin horns on the skin of both forearms.

Porokeratosis plantaris, palmaris, et disseminata. Report of a case and treatment with isotretinoin

McCallister RE, Estes SA, Yarbrough CL. *J Am Acad Dermatol* 1985; 13: 598–603.

A patient with familial PPPD received treatment with 1 mg/kg daily of isotretinoin. Significant clinical improvement was noted after 3 months of treatment. Two months after discontinuation of treatment a gradual recurrence was observed.

A case of extensive linear porokeratosis with evaluation of topical tretinoin versus 5-fluorouracil as treatment modalities

Grover C, Goel A, Nanda S, Khurana N, Reddy BS. *J Dermatol* 2005; 32: 1000–4.

One patient with LP was treated with topical tretinoin and 5-fluorouracil. Both agents were efficacious, but tretinoin was better tolerated.

Calcipotriol and adapalene therapy for disseminated superficial actinic porokeratosis

Nakamura Y, Yamaguchi M, Nakamura A, Muto M. Indian J Dermatol Venereol Leprol 2014; 80: 373–4.

Calcipotriol 0.005% ointment was applied in the morning and adapalene (0.1%) gel at night. After 3 months the skin lesions improved substantially, leaving only slight hyperpigmentation.

Treatment of porokeratosis of Mibelli with CO₂ laser vaporization versus surgical excision with split-thickness skin graft

Rabbin PE, Baldwin HE. J Dermatol Surg Oncol 1993; 19: 199–202.

CO₂ vaporization resulted in better cosmetic and functional improvement than split-skin grafting in the same patient.

Treatment of lichen amyloidosis (LA) and disseminated superficial porokeratosis (DSP) with frequency-doubled Q-switched Nd:YAG laser

Liu HT. Dermatol Surg 2000; 26: 958–62.

A patient's face and arms were treated four times, 1 month apart, resulting in marked improvement, but not complete clearance, of the lesions.

Successful treatment of porokeratosis with 585 nm pulsed dye laser irradiation

Alster TS, Nanni CA. Cutis 1999; 63: 265–6.

This is a case of LP that responded to a series of 585-nm pulsed dye laser treatments.

Treatment of disseminated superficial actinic porokeratosis (DSAP) with the Q-switched ruby laser

Lolis MS, Marmur ES. J Cosmet Laser Ther 2008; 10: 124–7.

This patient received three treatments with Q-switched ruby laser (694 nm) with good improvement.

Fractional photothermolysis: a novel treatment for disseminated superficial actinic porokeratosis

Chrastil B, Glaich AS, Goldberg LH, Friedman PM. Arch Dermatol 2007; 143: 1450–2.

Two patients received three to six courses of fractionated

photothermolysis (erbium-doped fiber laser). Both patients reported 50% improvement.

Disseminated superficial actinic porokeratosis improved with fractional 1927-nm laser treatments

Ross NA, Rosenbaum LE, Saedi N, Arndt KA, Dover JS. *J Cosmet Laser Ther* 2016; 18: 53–5.

Two patients were successfully treated with the 1927-nm thulium fiber fractional laser.

Unconventional use of intense pulsed light

Piccolo D, Di Marcantonio D, Crisman G, Cannarozzo G, Sannino M, Chiricozzi A, et al. *Biomed Res Int* 2014: 1–10.

Successful use of IPL in a series of 10 cases. Split 550-nm filter pulses, of 5 to 10 msec, with a 10-msec delay, and fluence of 10 to 12 J/cm² were applied up to four times at intervals of 20 to 30 days.

Topical photodynamic therapy in disseminated superficial actinic porokeratosis

Nayeemuddin FA, Wong M, Yell J, Rhodes LE. *Clin Exp Dermatol* 2002; 27: 703–6.

A report on three patients treated with 20% aminolevulinic acid cream under occlusion for 5 hours before illumination with 100 J/cm² of broadband red light (Waldmann 1200). Resolution of two lesions of DSAP was observed in one case, but the response could not be reproduced in this or two other cases.

Successful treatment of disseminated superficial actinic porokeratosis with methyl aminolevulinate-photodynamic therapy

Cavicchini S, Tournalaki A. *J Dermatol Treat* 2006; 17: 190–1.

This case demonstrated a striking improvement in response to two treatments, 1 week apart, using methyl aminolevulinate cream 160 mg/g applied with occlusion for 3 hours before illumination with a red light (Aktilite) 37 J/cm².

Response of linear porokeratosis to photodynamic therapy in an 11-year-old girl

Garrido-Colmenero C, Ruiz-Villaverde R, Martínez-García E, Aneiros-Fernández J, Tercedor-Sánchez J. *J Dermatol Case Rep* 2015;

9: 118–9.

Methyl aminolevulinate hydrochloride cream 160 mg/g (Metvix) was applied under occlusion for 2 hours and lesions illuminated with a dose of 37 J/cm² (Aktilite) over 8 minutes. Treatment was repeated 3 weeks later. The authors assessed the result as good.

Successful treatment of porokeratosis of Mibelli with diamond fraise dermabrasion

Spencer JM, Katz BE. Arch Dermatol 1992; 128: 1187–8.

No recurrence observed at 15-month follow-up, but the lesion healed with slight hyperpigmentation and mild hypertrophy in a 79-year-old Filipino woman.

Linear porokeratosis: successful treatment with diamond fraise dermabrasion

Cohen PR, Held JL, Katz BE. J Am Acad Dermatol 1990; 23: 975–7.

An excellent cosmetic result. No recurrence or scarring observed after 8 months.

The use of fluor-hydroxy pulse peel in actinic porokeratosis

Teixeira SP, de Nascimento MM, Bagatin E, Hassun KM, Talarico S, Michalany N. Dermatol Surg 2005; 31: 1145–8.

This is a case of DSAP treated with a combination of a 70% glycolic peel and a 5% 5-fluorouracil solution every 2 weeks for 4 months. The result was improvement in the appearance and texture of the treated areas and reduced dyskeratosis and epidermal atypia.

Dexamethasone pulse treatment in disseminated porokeratosis of Mibelli

Verma KK, Singh OP. J Dermatol Sci 1994; 7: 71–2.

A familial case of progressive porokeratosis received pulses of 100 mg dexamethasone in 5% dextrose intravenously on 3 consecutive days in a month. No new lesions appeared after the first pulse, and clinical improvement was noted after four pulses. There was an 80% improvement after 18 pulses. The patient was then lost to follow-up.

Diclofenac sodium 3% gel as a potential treatment for disseminated superficial actinic porokeratosis

Marks S, Varma R, Cantrell W, Chen SC, Gold M, Muellenhoff M, et al. J Eur Acad Dermatol Venereol 2009; 23: 42–5.

An open-label, multicenter trial; 17 patients were treated with 3% diclofenac applied twice daily for 3 to 6 months to a target area. The areas treated progressed less than the untreated areas.

Treatment of disseminated superficial actinic porokeratosis with topical diclofenac gel: a case series

Vlachou C, Kanelleas A, Martin-Clavijo A, Berth-Jones J. *J Eur Acad Dermatol Venereol* 2008; 22: 1343–5.

Eight patients with DSAP were treated with 3% diclofenac gel (Solaraze gel) twice daily for at least 6 months. At 6 months a partial improvement was seen in two cases but no improvement in the others.

Treatment of porokeratosis of Mibelli with ingenol mebutate: a possible new therapeutic option

Kindem S, Serra-Guillén C, Sorní G, Guillén C, Sanmartín O. *JAMA Dermatol* 2015; 151: 85–6.

A patient was treated with two courses, separated by a month, of ingenol mebutate 0.015% gel, applied once daily for 3 consecutive days. Resolution of the hyperkeratotic annular component was observed, although the treatment did not improve the central area of atrophy and hypopigmentation.

Porokeratosis of Mibelli: successful treatment with 5% topical imiquimod and topical 5% 5-fluorouracil

Venkatarajan S, LeLeux TM, Yang D, Rosen T, Orengo I. *Dermatol Online J* 2010; 16: 10.

A patient with PM was treated with 5-fluorouracil twice a day and 5% imiquimod cream once a day for 12 weeks, leading to resolution of the lesion.

Photodynamic therapy combined with CO₂ laser vaporization on disseminated superficial actinic porokeratosis: a report of 2 cases on the face

Kim HS, Baek JH, Park YM, Kim HO, Lee JY. *Ann Dermatol* 2011; 23: S211–3.

Two patients were treated with CO₂ laser to the cornoid lamella followed by photodynamic therapy. There was marked response after four treatments.

Recalcitrant digital porokeratosis of Mibelli: a successful surgical treatment

Shahmoradi Z, Sadeghiyan H, Pourazizi M, Saber M, Abtahi-Naeini B. N Am J Med Sci 2015; 7: 295–6.

A case successfully treated by excision and split-thickness skin graft.

Inflammatory disseminated pruritic porokeratosis with a good response to ciclosporin

Montes-Torres A, Camarero-Mulas C, de Argila D, Gordillo C, Daudén E. Actas Dermo-Sifiliogr 2016; 107: 261–2.

Intense distressing pruritus was improved by ciclosporin, initially at 4 mg/kg day. Dose reduction below 1 mg/kg/day resulted in recurrence of pruritus. This is proposed to be a subgroup of highly symptomatic, inflammatory porokeratosis with a low risk of malignant transformation.

Use of this immunosuppressant drug would be contraindicated in most cases of porokeratosis, as the danger of promoting malignancy outweighs the severity of the symptoms.

Treatment of porokeratosis of Mibelli with cantharidin

Levitt JO, Keeley BR, Phelps RG. J Am Acad Dermatol 2013; 69: e254–5.

Two cases of porokeratosis of Mibelli treated successfully with one application of a thin film of cantharidin to the circumference of the lesion.

Porphyria cutanea tarda

Maureen B. Poh-Fitzpatrick

The term *porphyria cutanea tarda* (PCT) encompasses several related inherited or acquired disorders in which insufficient hepatic

uroporphyrinogen decarboxylase enzyme activity causes overproduction of polycarboxylated porphyrins. These porphyrins mediate cutaneous photosensitivity manifested as fragility, bullae, hypertrichosis, dyspigmentation, sclerodermoid features, and scarring. PCT usually presents in adults but occasionally in children. Multiple factors may contribute to its expression: mutant uroporphyrinogen decarboxylase genes, hemochromatosis (HFE) genes, or other predisposing genetic determinants; ethanol abuse; smoking; medicinal estrogen; iron overload; hepatitis and/or human immunodeficiency viral infections (HIV); chronic dialysis treatment; toxic aromatic hydrocarbon exposure; and, rarely, hepatic tumors. Increased tissue iron, a common feature of alcoholism, hepatitis C infection, hemochromatosis, and end-stage renal disease, plays a central role in the pathogenesis of PCT. Iron-dependent partial oxidation of uroporphyrinogen to uroporphomethene, a competitive inhibitor of uroporphyrinogen decarboxylase, may be the mechanism by which its activity is reduced in PCT (Phillips et al. Proc Natl Acad Sci USA 2007; 104: 5079–84). Iron-enhanced complete oxidation of porphyrinogens accumulated due to inhibited enzyme activity yields photoactive porphyrins. Hepatic siderosis or porphyrin crystallization in hepatocytes may lead to hepatocellular carcinoma in long-standing active PCT. Ferropdepletion by serial phlebotomy is the preferred first-line therapy for PCT patients with iron overload.

Management Strategy

Precise diagnosis is essential because optimal management calls for remission induction using strategies inappropriate for other porphyrias or pseudoporphyrias. Associated disorders that may influence management (viral infections, hemochromatosis, or other causes of iron overload; lupus erythematosus; diabetes mellitus; anemias) should be identified. Sun exposure and mechanical skin trauma should be minimized until full clinical remission is achieved. Eliminating contributory factors and pursuing ferropdepletion by *serial phlebotomy*, *iron chelation*, or *erythropoiesis stimulation*, or increasing porphyrin excretion with *chloroquine* or *hydroxychloroquine*, can reproducibly induce biochemical and clinical remissions. Phlebotomy and hydroxychloroquine protocols adjusted for pediatric parameters are available. Alternative therapies are less well established. Porphyrin excretion can also be increased by *enteric sorbents* or

metabolic alkalization. Antiviral drugs may benefit PCT coincident with hepatitis C or HIV infections. *Vitamins E and C, plasmapheresis or plasma exchange, high-flux hemodialysis, and cimetidine* have had limited use. Hepatoerythropoietic porphyria, caused by coinheritance of two uroporphyrinogen decarboxylase gene mutations, resists induction of remission and thus requires lifelong vigilant photoprotection. *Photothermolysis* using light with selected wavelengths may reduce persistent hypertrichosis.

Specific Investigations

- Porphyrin concentrations and types in erythrocytes, serum or urine, feces
- Hematologic and iron profiles, serum ferritin, hemochromatosis gene analysis
- Liver function profile; serum α -fetoprotein level, liver imaging, liver biopsy if clinically indicated
- Hepatitis A, B, and C and human immunodeficiency viral serologies
- Fasting blood glucose
- Serum antinuclear antibody
- Mutation analysis of the uroporphyrinogen decarboxylase gene

Hepatitis C, porphyria cutanea tarda and liver iron: an update

Ryan Caballes F, Sendi H, Bonkovsky HL. Liver Int 2012; 32: 880–93.

A review emphasizing pathophysiologic roles of hepatitis C virus, iron-facilitated oxidative stress, and hepcidin (a key regulator of iron absorption and metabolism that is downregulated in PCT). Treatment guidelines are offered.

Porphyria cutanea tarda, hepatitis C, and HFE gene mutations in North America

Bonkovsky HL, Poh-Fitzpatrick MB, Pimstone N, Obando J, Di Bisceglie A, Tattrie C, et al. Hepatology 1998; 27: 1661–9.

Of 70 American patients with PCT, 53% had evidence of hepatitis C infection, and 43% of 26 patients had HFE gene mutations associated with hereditary hemochromatosis.

Hepatocellular carcinoma risk in patients with porphyria cutanea

tarda

Gisbert JP, Garcia-Buey L, Alonso A, Rubio S, Hernandez A, Pajares JM, et al. Eur J Gastroenterol Hepatol 2004; 16: 689–92.

Recommendations include viral hepatitis serologies and liver biopsy at initial evaluation. PCT patients with hepatitis C infection or advanced fibrosis/cirrhosis should be monitored with semiannual ultrasonography and serum α -fetoprotein testing.

The decision for liver biopsy should be weighed carefully. Patients without risk factors for hepatic siderosis or other liver pathology (e.g., women with estrogen use as the only PCT-inducing factor) may not need this invasive procedure.

First-Line Therapies

• Opaque sunscreens, physical sunlight barriers	C
• Serial phlebotomies	B
• Chloroquine, hydroxychloroquine	B

Efficiency of opaque photoprotective agents in the visible light range

Kaye ET, Levin JA, Blank IH, Arndt KA, Anderson RR. Arch Dermatol 1991; 127: 351–5.

Efficacy and quality of sunscreens containing zinc oxide, titanium dioxide, and iron oxide are described.

Minimizing sunlight exposure by lifestyle changes, opaque sunscreens, protective clothing, window glass barrier filters, etc., is essential until photosensitivity remits completely.

Treatment of porphyria cutanea tarda by phlebotomy

Ippen H. Semin Hematol 1977; 14: 253–9.

Repeated venesection resulted in reduction of porphyrins and serum iron, improvement of photocutaneous lesions, and normalization of liver function tests in the majority of 351 patients.

Phlebotomy schedules should be adjusted to the tolerance of individual patients, typically ranging from 200 to 500 mL of whole blood at twice-

weekly to fortnightly or monthly intervals. Keeping hemoglobin over 10 to 11 g/dL minimizes symptoms of iatrogenic anemia.

Childhood-onset familial porphyria cutanea tarda: effects of therapeutic phlebotomy

Poh-Fitzpatrick MB, Honig PJ, Kim HC, Sassa S. J Am Acad Dermatol 1992; 27: 896–900.

Pediatric phlebotomy guidelines are described.

Plasma ferritin levels as a guide to the treatment of porphyria cutanea tarda by venesection

Ratnaike S, Blake D, Campbell D, Cowen P, Varigos G. Australas J Dermatol 1988; 29: 3–8.

Phlebotomy can be terminated when iron stores, as reflected by plasma ferritin concentration, have fallen to low-normal levels.

Reduction of porphyrins in plasma (or serum or urine) and clinical improvement typically begin during therapy and continue for weeks to months after venesection stops. Clinical improvement precedes full biochemical normalization.

Treatment of porphyria cutanea tarda with chloroquine

Kordač V, Semrádová M. Br J Dermatol 1974; 90: 95–100.

Twenty-one adults received oral chloroquine 125 mg twice weekly until cutaneous blistering and fragility ceased and urinary uroporphyrins fell below three times the normal limit. Mean duration of treatment was 8.5 months (range 4–11 months) in 19 patients. Serum transaminases and urinary uroporphyrins rose during initial weeks of therapy and then progressively diminished.

Chloroquine risks include irreversible retinopathy after large cumulative doses (>100–300 g), but this is infrequent at dose rates <4 mg/kg daily (<6.5 mg/kg daily for hydroxychloroquine). Ophthalmologic examination is recommended at baseline; if normal, no further testing is needed unless treatment continues beyond 5 years (unlikely for PCT). The risk of hemolysis can be minimized by pretreatment testing for glucose-6-phosphate dehydrogenase deficiency and interval monitoring of hematologic profiles during therapy.

Childhood-onset porphyria cutanea tarda: successful therapy with low-dose hydroxychloroquine (Plaquenil)

Bruce AJ, Ahmed I. J Am Acad Dermatol 1998; 38: 810–4.

A 4-year-old child given hydroxychloroquine 3 mg/kg twice weekly for 14 months, plus vitamin E 200 U/day, achieved remission without adverse side effects.

Choice of therapy in porphyria cutanea tarda

Adjarov D, Naydenova E, Ivanov E, Ivanova A. Clin Exp Dermatol 1996; 21: 461–2.

The effectiveness of phlebotomy (500 mL weekly for 4 weeks, then monthly) versus oral chloroquine 250 mg twice weekly alone versus combined phlebotomy/chloroquine therapies was retrospectively analyzed in unequal groups totaling 115 patients. Remissions occurred more quickly and reliably with phlebotomy than with chloroquine. Combined therapy shortened the mean total treatment course by approximately 1.5 months only when initial urinary uroporphyrin levels exceeded 3000 nmol/24 hours.

Others found remissions more rapid with chloroquine than with venesection (10.2 months in 24 patients, 12.5 months in 15 patients, respectively). Combination therapy was quickest (3.5 months in 20 patients) (Seubert S, Seubert A, Stella AM, Guzman H, Battle A. Z Hautkr 1990; 65: 223–5). In another study, urinary porphyrin excretion significantly improved in 22 of 30 hydroxychloroquine-treated subjects (200 mg twice weekly), but in only eight of 31 phlebotomy-treated subjects (400 mL whole blood twice monthly) after 1 year, while clinical improvement was similar in both groups. (Cainelli T, Di Padova C, Marchesi L, Gori G, Rovagnati P, Podenzani SA, et al. Br J Dermatol 1983; 108: 593–600). Low-dose hydroxychloroquine (13 subjects) was similarly effective as biweekly phlebotomy (17 subjects) in inducing normal plasma porphyrin levels (6.1 and 6.9 months, respectively). (Singal AK, Kormos-Hallenberg C, Lee C, Sadagoparamanujam VM, Grady JJ, Freeman DH, et al. Clin Gastroenterol Hepatol 2012; 10: 1402–9).

Hemochromatosis (HFE) gene mutations and response to chloroquine in porphyria cutanea tarda

Stolzel U, Kostler E, Schuppan D, Richter M, Wollina U, Doss MO, et al. Arch Dermatol 2003; 139: 379–80.

Chloroquine was effective in heterozygotes with one of the major HFE mutations (C282Y, H63D) or in compound heterozygotes, but C282Y homozygotes failed to improve; serum iron decreased only in patients with PCT and wild-type HFE. Phlebotomy was the recommended therapy for patients with PCT and HFE gene

mutations.

Second-Line Therapies

• Iron chelation	B, C
• Erythropoietin	E

Liver iron overload and desferrioxamine treatment of porphyria cutanea tarda

Rocchi E, Cassanelli M, Borghi A, Paolillo F, Pradelli M, Pellizzardi S, et al. *Dermatologica* 1991; 182: 27–31.

Ferrodepletion by desferrioxamine 1.5 g subcutaneous pump infusions 5 days/week (18 patients) or 200 mg/kg infused intravenously once weekly (5 patients) or by serial phlebotomies (22 patients) led to clinical remission after nearly 6 months with all treatments. Normalization of serum ferritin and uroporphyrins occurred at approximately 11 months with chelation and approximately 13 months with venesection; liver function improved with both modalities.

Subcutaneous chelation is expensive and cumbersome and thus is best reserved for cases in which first-line therapies are inadequate or inappropriate.

Deferasirox for porphyria cutanea tarda

Pandya AG, Nezafati KA, Ashe-Randolph M, Yalamanchili R. *Arch Dermatol* 2012; 148: 898–901.

Among eight patients considered to have PCT treated with deferasirox 250 to 500 mg/day orally for 6 months, reductions in blistering (eight), urinary porphyrins (six), and serum ferritin levels (eight) resulted.

Although true PCT was questionable in two cases, these promising results encourage larger confirmatory trials.

Successful treatment of haemodialysis-related porphyria cutanea tarda with deferoxamine

Pitche P, Corrin E, Wolkenstein P, Revuz J, Bagot M. *Ann Dermatol Venereol* 2003; 130: 37–9.

Intravenous deferoxamine 40 mg/kg weekly for 6 weeks led to normalization of clinical and biological signs of PCT in one patient that persisted for 12 months in the setting of end-stage renal disease and chronic hemodialysis.

Successful treatment of hemodialysis-related porphyria cutanea tarda with deferoxamine

Stockenhuber F, Kurz R, Grimm G, Moser G, Balcke, P. *Nephron* 1990; 55: 321–4.

Erythropoietin for the treatment of porphyria cutanea tarda in a patient on long-term hemodialysis

Anderson KE, Goeger DE, Carson RW, Lee SM, Stead RB. *N Engl J Med* 1990; 322: 315–7.

An end-stage renal disease patient treated with chronic hemodialysis received erythropoietin 150 U/kg after every dialysis session, plus several low-volume phlebotomies. Reticulocytosis and lowered serum ferritin and plasma porphyrin levels followed, and blistering resolved.

Management of porphyria cutanea tarda in the setting of chronic renal failure: a case report and review

Shieh S, Cohen JL, Lim HW. *J Am Acad Dermatol* 2000; 42: 645–52.

High-dose erythropoietin (80–360 U/kg U thrice weekly) plus 100-mL phlebotomies weekly for several months was followed by clinical remission, normalized serum ferritin, and 10-fold lower plasma porphyrin levels in one patient. Positive and negative aspects of alternative treatment for PCT in the context of renal failure are reviewed, including several third-line therapies listed next.

Third-Line Therapies

• Antiviral therapies for hepatitis C virus or human immunodeficiency virus	E
• Vitamin E, vitamin C	D
• Plasmapheresis, plasma exchange	D
• High-flux hemodialysis	D
• Enteric sorbents (cholestyramine, activated charcoal)	D
• Metabolic alkalization by oral sodium bicarbonate	D
• Cimetidine	E
• Photothermolysis	E

Highly active antiretroviral therapy leading to resolution of porphyria cutanea tarda in a patient with AIDS and hepatitis C

Rich JD, Mylonakis E, Nossa R, Chapnick RM. Dig Dis Sci 1999; 44: 1034–7.

The association between PCT and HIV infection is less well established than that of PCT with hepatitis C infection. Coinfection with hepatitis C virus may trigger PCT in patients with HIV infection.

Dramatic resolution of skin lesions associated with porphyria cutanea tarda – interferon-alpha therapy in a case of chronic hepatitis C

Shiekh MY, Wright RA, Burruss JB. Dig Dis Sci 1998; 43: 529–33.

Anecdotal reports of PCT improvement during interferon treatment of concurrent hepatitis C infection must be balanced against those of PCT appearing 1–4 months after initiation of interferon/ribavirin protocols (Thevenot T, Bachmeyer C, Hammi R, Dumouchel P, Ducamp-Posak I, Cadranel JF. J Hepatol 2005; 42: 607–8). Ribavirin-induced hemolysis may increase liver iron, thereby triggering PCT. Measures to reduce liver iron (e.g., phlebotomy) prior to initiation of interferon, especially when combined with ribavirin, are recommended in patients with viral hepatitis and coincident symptomatic PCT or indices of excess tissue iron stores.

Treatment of chronic hepatitis with boceprevir leads to remission of porphyria cutanea tarda

Aguilera M, Laguno M, To-Figueras J. Br J Dermatol 2014; 171: 1595–6.

A patient with both HIV and hepatitis C infections whose PCT had not improved with chloroquine and phlebotomy achieved biochemical and clinical remission 2 months after boceprevir was

added to a pegylated interferon/ribavirin regimen to which he had been previously unresponsive.

High-dose vitamin E lowers urine porphyrin levels in patients affected by porphyria cutanea tarda

Pinelli A, Trivulzio S, Tomasoni L, Bertolini B, Pinelli G. Pharmacol Res 2002; 45: 355–9.

Oral vitamin E (1 g daily) reduced urinary uroporphyrin levels and attenuated skin lesions during a 4-week trial in five subjects, who continued to imbibe at least 1.5 L of red wine each day.

Although urinary porphyrin levels were lower during vitamin E treatment, they remained very abnormal. Convincing confirmatory studies are needed.

Porphyria cutanea tarda: a possible role for ascorbic acid

Anderson KE. Hepatology 2007; 45: 6–8.

Deficiencies of vitamin C (ascorbic acid) and perhaps other antioxidants may facilitate development of PCT. Adequate dietary or supplemental vitamin C and other nutrients should be ingested by patients with PCT but should not usually be used as primary therapy instead of phlebotomy or chloroquine/hydroxychloroquine.

Removal of plasma porphyrins with high-flux hemodialysis in porphyria cutanea tarda associated with end stage renal disease

Carson RW, Dunnigan EJ, DuBose TD Jr, Goeger DE, Anderson KE. J Am Soc Nephrol 1992; 2: 1445–50.

High-flux hemodialysis removes porphyrins more effectively than conventional techniques.

Treatment of hemodialysis related porphyria cutanea tarda with plasma exchange

Disler P, Day R, Burman N, Blekkenhorst G, Eales L. Am J Med 1982; 72: 989–93.

This may aid patients with PCT and chronic renal failure for whom other treatments are unavailable.

The adsorption of porphyrins and porphyria precursors by sorbents: a potential therapy for the porphyrias

Tishler PV, Gordon RJ, O'Connor JA. Meth Find Exp Clin Pharmacol 1982; 4: 125–31.

Metabolic alkalization therapy in porphyria cutanea tarda

Perry HO, Mullanax MG, Weigand SE. Arch Dermatol 1970; 102: 359–67.

Cimetidine in the treatment of porphyria cutanea tarda

Horie Y, Tanaka K, Okano J, Ohgi N, Kawasaki H, Yamamoto S, et al. Intern Med 1996; 35: 717–9.

In this report cimetidine reduced porphyrin levels within 2 weeks. This benign treatment might be offered to patients unwilling or unable to try standard therapeutic approaches.

Convincing confirmatory reports are needed.

Successful and safe treatment of hypertrichosis by high-intensity pulses of noncoherent light in a patient with hepatoerythropoietic porphyria

Garcia-Bravo M, Lopez-Gomez S, Segurado-Rodriguez MA, Morán-Jiménez MJ, Méndez M, Enriquez de Salamanca R, et al. Arch Dermatol Res 2004; 296: 139–40.

Hypertrichosis was almost completely removed after seven sessions, without development of skin lesions.

Port wine stain ("nevus flammeus")

Dawn Z. Eichenfield, and Lawrence F. Eichenfield

Port wine stains (PWS), also known as *nevus flammeus*, are benign capillary malformations of the superficial cutaneous vasculature. These lesions are almost always congenital, though they may be acquired secondary to trauma and, thus, may rarely develop in adolescence or adulthood. The head and neck are sites of predilection, but any part of the integument can be affected. Morphologically, these lesions present as light pink to red patches that typically grow

proportionately with the child's somatic growth. Unlike the salmon patch (also known as *nevus simplex* or *angel kiss*), which usually disappears within 1 or 2 years, untreated PWS persist throughout a patient's life and tend to darken with time. Confusing this clinical picture is the fact that PWS may appear to lighten during the first 3 to 6 months of life; this is a physiologic change most likely due to the decrease in blood hemoglobin concentration (typically 15–17 g/dL at birth to a nadir of 8–10 g/dL by age 3 months) and should not be interpreted as a sign of clinical resolution. Skin thickening and the development of surface irregularities (nodules or “blebs”) and soft tissue hypertrophy may also occur, especially in the V2 distribution. PWS may also present with an inflammatory component consisting of scaling, excoriations, oozing, and crusting, which resembles an eczematous dermatitis.

Although the exact molecular pathogenesis of these capillary malformations has yet to be elucidated, it is believed that complex, localized defects in pathways controlling embryogenesis and angiogenesis play crucial roles. Recent whole-genome sequencing of DNA from paired samples of affected and normal tissue from persons with Sturge–Weber syndrome (SWS) has shown that a nonsynonymous single-nucleotide-activating mutation in *GNAQ* (c.548G→A, p.Arg183Gln) encoding a $G\alpha_q$ protein responsible for the hydrolysis and inactivation of GTP and thus mediating increased downstream MAP kinase signaling is associated with both SWS-associated and nonsyndromic PWS. Mutations in *RASA1* encoding the p120-rasGTPase-activating protein (p120-rasGAP) along the Ras/MAP kinase pathway have been identified in patients with atypical capillary malformations, with or without concurrent arteriovenous malformations or arteriovenous fistulas. Evolving work using targeted next-generation sequencing has uncovered several somatic mutations seen with PWS in association with overgrowth syndromes (e.g., *PIK3CA*, *GNA11*). Further research is needed to elucidate how these genes influence PWS development, why certain PWS seem to follow specific anatomic distributions, and if therapies may be developed targeting specific genetic pathways.

In addition to being potentially cosmetically distressing and at risk for long-term deformation, PWS may be associated with serious physical, social, and psychological sequelae. The presentation of a PWS on the face in the V1 distribution, for example, has been classically linked to the development of ocular and/or neurologic

complications in the form of glaucoma or SWS, especially with complete unilateral involvement of V1; bilateral involvement of V1; or a combination of V1, V2, and V3. Of note, anatomic variation in the distribution of V1 and V2 at the medial and lateral canthus (the so-called *watershed areas*) has resulted in considerable difficulty in definitively defining distribution of a PWS occurring in these areas. Several papers have posited alternative methods of characterizing facial PWS and risk of SWS, highlighting segmental patterns that differ from traditional dermatomal designations. Two papers show that the distribution of facial PWS appears to follow the embryonic vasculature of the face instead of following the traditional delineation of the trigeminal nerve, with hemifacial (upper quarter and cheek involvement) and median (forehead) patterns representing the strongest predictor of SWS and possible later neural and ophthalmologic complications.

PWS may also be associated with limb overgrowth and complex malformations (e.g., capillary–venous, capillary–venous–lymphatic, capillary–arteriovenous); evaluation of nonfacial PWS for limb overgrowth or evidence of complex malformations may warrant consideration of magnetic resonance imaging/magnetic resonance angiography (MRI/MRA) if symptomatic and/or referral to genetics or multidisciplinary vascular lesion clinics for diagnostic evaluation and management.

Management Strategy

Because of the well-recognized, predictable physical and psychosocial comorbidities associated with PWS, many specialists advocate treatment of PWS as soon as possible after birth. Support for early intervention is based on the fact that the lesions themselves are physically smaller in size and comprise vessels that are smaller in diameter and more superficial; thus early treatment may improve responsiveness, decrease the overall number of treatments, and reduce the likelihood of long-term adverse outcomes.

Many therapeutic modalities have been used to treat PWS, including surgical excision and grafting, dermabrasion, cryotherapy, sclerotherapy, radium implants, x-ray therapy, electrocautery, tattooing, and cosmetic camouflage. Vascular-targeted photodynamic therapy has also been used for patients with darker skin types, with long-term studies in the Chinese population demonstrating mixed

results and several serious complications. These modalities have limited results, and many—if not all of them—have been associated with unfavorable outcomes.

Various *lasers* have been used, including CO₂, Nd:YAG, argon, and copper vapor lasers, but results have been unsatisfactory, with the risk of scarring unacceptably high. Consequently, the *flashlamp-pumped pulsed dye laser* (PDL) is considered by most authorities to be the gold standard of treatment for PWS. A lack of controlled studies with single parameter differences has made it difficult to optimize treatment settings. In general, wavelengths of 585 to 595 nm, fluences of 4 to 13 J/cm², spot sizes of 2 to 10 mm, and pulse durations of about 0.45 ms (short-pulse PDL characterized by the clinical end point of immediate purpura) to 1.5 ms (long-pulse PDL) are generally utilized, allowing for a deep, safe, and specific action that is confined to the targeted vasculature. Lightening and/or reduction in size of the stain is directly related to the number of treatments. Initial treatments usually give the highest percentage of improvement. Generally, the smaller, more superficial vessels are targeted first, and deeper, larger-caliber vessels may require longer pulse durations or longer wavelengths. Graying of tissue is an indication of possible overtreatment. Other modalities have been used for refractory PWS, including long-pulsed alexandrite and Nd:YAG lasers, intense-pulsed light, and photodynamic therapy.

Swelling, erythema, and pain are frequently present immediately after treatment with PDL. Other potential adverse events include postinflammatory dyspigmentation (especially in darker-skinned patients), immediate postlaser purpura, and recurrence of the lesion itself. Rarely, blistering, crusting, scarring, and infection may also occur. For these reasons, a test area may be performed before a full treatment session. Sun exposure can drastically affect pigmentary changes, and sun avoidance/protection should be optimized between treatment sessions. Before and after photos are a helpful tool for demonstrating clinical efficacy and for assuaging patient and family fears.

Cooling the skin via an attached device utilizing a targeted cryogenic spray or by application of a cool air machine is crucial to minimizing damage to surrounding tissues and reducing the risk of postoperative complications. Cold compresses and/or bags of ice applied immediately to the treated area are also useful for preventing postoperative complications.

Measures to overcome the pain and anxiety associated with laser use include topical anesthetics such as lidocaine 4% gel, eutectic mixture of 2.5% lidocaine and 2.5% prilocaine, local lidocaine infiltration, nerve block, sedation, and general anesthesia. Concerns about general anesthesia and potential neurotoxic effects in young children have been raised and should be considered in discussions about approaches to therapy, though not negating the utility and effectiveness of early laser therapy.

Topical daily treatment with 1% rapamycin cream after laser treatment may improve responsiveness to laser therapy through an unknown mechanism, possibly by decreasing vascular proliferation through the mTOR and HIF-1 α pathway, resulting in statistically significant photographic improvements and patient-described subjective improvement of their lesions.

Specific Investigations

- Ophthalmologic examination in infants with V1 PWS (or equivalent facial pattern).
- MRI/MRA may be considered in infants with V1 PWS, hemifacial, or median patterns or suspected SWS to delineate the extent of central nervous system (CNS) abnormalities and in PWS that may be associated with complex vascular malformations or overgrowth syndromes. CT is an alternative, but not preferred, imaging method.
- Genetic testing for mutation analysis can be considered.

Facial port wine stain and Sturge–Weber syndrome

Enjolras O, Riche MC, Merland JJ. *Pediatrics* 1985; 76: 48–51.

SWS was present in 28.5% of patients with PWS covering the V1 trigeminal sensory area alone or in association with V2 and V3, and 9.5% had glaucoma. None of the patients with PWS located in the V2 and/or the V3 areas had ocular or pial vascular abnormalities.

Sturge–Weber syndrome in patients with facial port-wine stain

Piram M, Lorette G, Sirinelli D, Herbreteau D, Giraudeau B, Maruani A. *Pediatr Dermatol* 2012; 29: 32–37.

This cross-sectional study of 259 patients with facial PWS included 15 patients with a diagnosis of SWS. All patients with SWS showed

involvement of the V1 trigeminal cutaneous area. SWS was significantly associated with bilateral topography of the PWS, its extension to another territory, and involvement of the upper eyelid.

This study provides valuable data to support risk stratification of a facial PWS for SWS and glaucoma based on anatomic distribution.

Facial port-wine stain: when to worry?

Melancon JM, Dohil MA, Eichenfield LF. *Pediatr Dermatol* 2012; 29: 131–3.

A “comment” on the aforementioned article by Piram et al. discussing the anatomic variations that have made direct comparison of the available literature difficult and providing insight in terms of management.

Location of port wine stains and the likelihood of ophthalmic and/or central nervous system complications

Tallman B, Tan OT, Morelli JG, Piepenbrink J, Stafford TJ, Trainor S, et al. *Pediatrics* 1991; 87: 323–7.

Among patients with trigeminal PWS, 8% had evidence of eye and/or CNS involvement. PWS of the eyelids, bilateral distribution, and unilateral PWS involving all three branches of the trigeminal nerve were associated with a significantly higher likelihood of having eye and/or CNS complications.

Patients with such presentations should be screened for glaucoma, and the risk of CNS involvement should be discussed with the family and appropriate testing considered.

New vascular classification of port-wine stains: improving prediction of Sturge-Weber risk

Waelchli R, Aylett SE, Robinson K, Chong WK, Martinez AE, Kinsler VA. *Br J Dermatol* 2014; 171: 861–7.

Of 192 children with facial PWS seen in 2011 to 2013, PWS involving any part of the forehead, which involves all three divisions of the trigeminal nerve, which corresponds well to the embryonic vascular development of the face, was the best predictor of adverse outcomes.

Children with PWS on any part of the forehead should undergo ophthalmologic evaluation and brain MRI.

A prospective study of risk for Sturge-Weber syndrome in

children with upper facial port-wine stain

Dutkiewicz AS, Ezzedine K, Mazereeuw-Hautier J, Lacour JP, Barbarot S, Vabres P, et al. J Am Acad Dermatol 2015; 72: 473–80.

In this prospective multicenter study of 66 patients, 11 presented with SWS and 4 had suspected SWS without neurologic manifestations. These patients predominantly had hemifacial or median PWS patterns that were high risk for SWS.

Hemifacial or median PWS patterns conform to areas of somatic mosaicism and are high risk for SWS.

Sturge–Weber syndrome and dermatomal facial port wine stains: incidence, association with glaucoma, and pulsed tunable dye laser treatment effectiveness

Hennedige AA, Quaba AA, Al-Nikib K. Plast Reconstruct Surg 2008; 121: 1173–80.

In this study of 874 patients, SWS occurred in 3% of all patients with facial PWS and 10% of those whose PWS were in a dermatomal distribution. Although both SWS and glaucoma occurred in patients with only V1 involvement, the risk increased substantially with V1 + V2 and V1 + V2 + V3 involvement. No patients with only V3 involvement had eye or CNS findings.

Children at risk of SWS should have ophthalmologic examination in the neonatal period and require ophthalmologic follow-up because glaucoma may develop subsequent to initial presentation.

Sturge–Weber syndrome. The current neuroradiologic data

Boukobza M, Enjolras O, Cambra M, Merland J. J Radiol 2000; 81: 765–71.

Neonatal neuroimaging workup using CT or MRI may not demonstrate the pial anomaly and may be delayed or repeated after 6 to 12 months in an at-risk infant with V1 PWS.

First-Line Therapy

• Pulsed dye laser	B
--------------------	----------

Anatomic differences of port wine stains in response to treatment with pulsed dye laser

Renfro L, Geronemus RG. Arch Dermatol 1993; 129: 182–8.

Centrofacial lesions and lesions involving dermatome V2 responded less favorably than lesions located elsewhere on the head and neck.

Facial port wine stains in childhood: prediction of the rate of improvement as a function of the age of the patient, size and location of the port wine stain and the number of treatments with the pulsed dye (585 nm) laser

Nguyen CM, Yohn JJ, Huff C, Weston WL, Morelli JG. Br J Dermatol 1998; 138: 821–5.

Major determinants of treatment response, in order of decreasing importance, are PWS location, size, and patient age. The most successful responses are seen in young patients (under 1 year of age) with small PWS (<20 cm²) located over bony areas of the face, such as the central forehead. The greatest percentage of size reduction occurred after the first five treatments. There was less reduction in size with subsequent treatments.

Why do port-wine stains (PWS) on the lateral face respond better to pulsed dye laser (PDL) than those located on the central face?

Yu W, Ma G, Qiu Y, Chen H, Jin Y, Yang X, et al. J Am Acad Dermatol 2016; 74: 527–35.

In 13 patients with PWS who underwent PDL treatments in both central and lateral areas of the face, lateral facial PWS responded better to PDL treatments than did PWS located in the central face.

Efficacy of early treatment of facial port wine stains in newborns: a review of 49 cases

Chapas AM, Eickhorst K, Geronemus RG. Lasers Surg Med 2007; 39: 563–8.

Patients who received treatment with the cryogen spray-cooled 595-nm PDL before 6 months of age achieved a mean 88.6% clearance after 1 year after an average of nine treatments. Higher clearance rates were observed for smaller lesions and V1 dermatome lesions.

Treatment of port wine stains (capillary malformations) with the flash lamp pumped pulsed dye laser

Goldman MP, Fitzpatrick RE, Ruiz-Esparza J. J Pediatr 1993; 122: 71–7.

Initial treatment in children with PWS results in approximately 40% improvement, and each subsequent treatment up to six adds a further increment of 10% improvement. Treatments should be continued as long as there is incremental improvement.

Double pass 595 nm pulsed dye laser at a 6 minute interval for the treatment of port-wine stains is not more effective than single pass

Peters MA, Drooge AM, Wolkerstorfer A, van Gemert MJ, van der Veen JP, Bos JD, et al. Lasers Surg Med 2012; 44: 199–204.

In each patient ($n = 16$), two similar PWS areas were randomly allocated to PDL with either a single pass (595 nm; 12 J/cm² fluence; 7-mm spot; 1.5-ms pulse duration) or, as a new treatment, a double pass (11 J/cm²). Test areas were treated two times, 8 weeks apart. At 3 months, follow-up, no significant difference was noted in any of the outcomes.

High-fluence modified pulsed dye laser photocoagulation with dynamic cooling of port wine stains in infancy

Geronemus RG, Quintana AT, Lou WW, Kauvar AN. Arch Dermatol 2000; 136: 942–3.

Early intervention using a modified PDL with a longer wavelength (595 nm), broader pulse width (1.5 ms), dynamic cooling spray, and high-energy fluences can result in lightening or clearing of PWS with minimal risk of adverse effects.

Redarkening of port-wine stains 10 years after pulsed-dye-laser treatment

Huikeshoven M, Koster PH, deBorgie CA, Beek JF, van Gemert MJ, van der Horst CM. N Engl J Med 2007; 356: 1235–40.

After follow-up for a median of 9.5 years, PWS, on average, were darker than when measured after the last of the five initial treatments, although still lighter than when measured before treatment.

Patients should be counseled that due to progressive ectasia of PWS vessels, “recurrence,” or redarkening of the stain, is a possibility.

Effects of percutaneous local anaesthetics on pain reduction during pulse dye laser treatment of port wine stains

McCafferty DF, Woolfson AD, Handley J, Allen G. Br J Anaesth 1997; 78: 286–9.

Both EMLA and 4% tetracaine gel were statistically superior to placebo in reducing pain caused by the laser treatment.

Effect of the topical anesthetic EMLA on the efficacy of pulsed dye laser treatment of port wine stains

Ashinoff R, Geronemus RG. J Dermatol Surg Oncol 1990; 16: 1008–11.

The use of topical anesthetic creams or sedating agents has been shown not to interfere with laser therapy.

Cryogen spray cooling and higher fluence pulsed dye laser treatment improve port wine stain clearance while minimizing epidermal damage

Chang CJ, Nelson JS. Dermatol Surg 1999; 25: 767–72.

A retrospective study of 196 patients with head and neck PWS, indicating the statistically significant advantage of using a cryogen spray-cooling device with PDL by permitting higher light dosages and a subsequently higher clearance rate without increasing the rate of complications.

General anesthesia for pediatric dermatologic procedures: risks and complications

Cunningham BB, Gigler V, Wang K, Eichenfield LF, Friedlander SF, Garden JM, et al. Arch Dermatol 2005; 141: 573–6.

A review of 881 cases performed on 269 pediatric patients, 88% of which were PDL treatment of vascular lesions, including PWS. There were no life-threatening events, and the mortality rate was zero.

The use of general anesthesia for dermatologic procedures performed in a children's hospital setting is safe with a low rate of complications.

Anesthetic neurotoxicity—clinical implications of animal models

Rappaport BA, Suresh S, Hertz S, Evers AS, Orser BA. N Engl J Med 2015; 372: 796–7.

A perspective paper discussing possible animal studies and ongoing clinical studies in children undergoing prolonged or repeated general anesthesia.

While awaiting clinical studies that can definitively determine whether anesthetics cause injury in humans, surgeons, anesthesiologists, and parents should consider carefully how urgently surgery is needed, particularly in

children under 3 years of age.

US Safety Warning: about using general anesthetics and sedation drugs in young children

<https://www.fda.gov/downloads/Drugs/DrugSafety/UCM533197.pdf>

The U.S. Food and Drug Administration (FDA) has communicated that repeated or lengthy use of general anesthetic and sedation drugs during surgeries or procedures in children younger than 3 years may affect the development of children's brains. Health care professionals should balance the benefits of appropriate anesthesia in young children against the potential risks. Discuss with parents, caregivers, and pregnant women the benefits, risks, and appropriate timing of surgery or procedures requiring anesthetic and sedation drugs. Anesthetic and sedation drugs are necessary for infants, children, and pregnant women who require surgery or other painful and stressful procedures, especially when they face life-threatening conditions requiring surgery that should not be delayed. In addition, untreated pain can be harmful to children and their developing nervous systems.

Second-Line Therapies

• Alexandrite 755-nm laser	B
• Neodymium:yttrium–aluminum–garnet (Nd:YAG) laser	B
• Intense pulsed light source	B

Split-face comparison of intense pulsed light with short- and long-pulsed dye lasers for the treatment of port-wine stains

Babilas P, Schremi S, Eames T, Hohenleutner U, Szeimies RM, Landthaler M. *Lasers Surg Med* 2010; 42: 720–7.

This study evaluated the efficacy and side effects of intense pulsed light (IPL) treatment of PWS in a direct comparison to the short-pulsed dye laser (SPDL) and the long-pulsed dye laser (LPDL). Test spots were applied with IPL (555–950 nm; pulse duration 8–14 ms [single pulse]; fluence 11 to 17.3 J/cm²) versus SPDL (585 nm; pulse duration 0.45 ms; fluence 6 J/cm²) versus LPDL (585/590/595/600 nm;

pulse duration 1.5 ms; fluence 12/14/16/18 J/cm²) in a side-by-side modus. Subjects included those with both untreated ($n = 11$) and previously treated ($n = 14$) PWS, and lesion clearance was evaluated by three blinded investigators based on follow-up photography 6 weeks after treatment. In both untreated and previously treated PWS, IPL treatments were rated significantly better than SPDL; in both groups, IPL and LPDL treatments did not differ significantly. Side effects were rare with all modalities.

Intense pulsed light source for the treatment of dye laser resistant port-wine stains

Bjerring P, Christiansen K, Troilius A. J Cosmet Laser Ther 2003; 5: 7–13.

A greater than 50% reduction was achieved after four treatments with IPL source in 46.7% of 15 patients with PWS previously treated by PDL. None of the lesions located in V2 responded.

There are several case reports of successful treatment of resistant PWS with IPL source. However, controlled studies are needed to confirm this observation.

Treatment of hypertrophic and resistant port wine stains with a 755 nm laser: a case series of 20 patients

Izikson L, Nelson JS, Anderson RR. Lasers Surg Med 2009; 41: 427–32.

Many PWS that respond well initially to PDL treatment may reach a response plateau, and many hypertrophic PWS are less responsive to PDL in general. Based on the theory of selective photothermolysis, the deoxyhemoglobin and oxyhemoglobin in the deeper vessels within these lesions may be targeted with a 755-nm laser. This retrospective case review of 20 patients demonstrated the utility of the 755-nm laser for improving hypertrophic and treatment-resistant PWS in both adult and pediatric patients. Most commonly encountered complications included pain, edema, bullae, crusting, and rare scarring.

Some scarring with the 755-nm laser is inevitable if one uses the laser enough; however, the technique for PWS is difficult enough that these authors recommend its use by experienced laser specialists only.

Treatment endpoints for resistant port wine stains with a 755 nm laser

Izikson L, Anderson RR. J Cosmet Laser Ther 2009; 11: 52–5.

Deeper vessels may be targeted with the near-infrared light from the 755-nm laser. It is more difficult to assess laser-induced changes within the deeper dermis, however, and adverse effects include deep dermal burns. The authors treated a resistant PWS with a 755-nm laser at high fluences (40–100 J/cm²; 1.5-ms pulse duration) with a dynamic cooling device. Mild-to-moderate lightening of the PWS was associated with the immediate clinical end point of a transient gray color that gradually evolved into persistent deep purpura within several minutes. The authors recommend judicious use of 755 nm for resistant PWS.

Long-pulsed neodymium:yttrium–aluminum–garnet laser treatment for port wine stains

Yang MU, Yaroslavsky AN, Farinelli WA, Flotte TJ, Rius-Diaz F, Tsao S, et al. *J Am Acad Dermatol* 2005; 52: 480–90.

Treatment achieved similar 50% to 75% clearing with both the PDL and the Nd:YAG laser at minimum purpura dose (MPD). The PDL performed significantly better than the Nd:YAG at fluences lower than 1 MPD, and scarring occurred in the only patient who was treated with the Nd:YAG laser at a fluence greater than 1 MPD.

Nd:YAG may be an alternative treatment option, although there is a narrow margin at which this laser is both safe and effective.

Combined 595 nm and 1064 nm laser irradiation of recalcitrant and hypertrophic port-wine stains in children and adults

Alster TS, Tanzi EL. *Dermatol Surg* 2009; 35: 914–9.

The purpose of this study was to evaluate the safety and efficacy of a novel device that delivers sequential pulses of 595-nm and 1064-nm wavelengths in the treatment of recalcitrant and hypertrophic PWS. Twenty-five subjects (aged 2–75) with skin types I to III were identified showing incomplete clearance after 10+ (mean = 16.9) prior PDL treatments. Nineteen had a PWS in a trigeminal location and six on the extremities. Subjects were treated at 6- to 8-week intervals. Continued improvement was noted in these resistant lesions. Side effects included transient erythema, edema, mild purpura, and rare vesicle formation.

A direct comparison of pulsed dye, alexandrite, KTP and Nd:YAG lasers and IPL in patients with previously treated capillary malformations

McGill DJ, MacLaren W, Mackay IR. *Lasers Surg Med* 2008; 40: 390–8.

Patients with PWS previously treated with PDL were treated using the alexandrite, KTP (potassium titanyl phosphate), and Nd:YAG lasers and IPL, with additional PDL patches as a control. Fifty-five percent of patients achieved some lightening with the alexandrite laser, although a high percentage also developed hyperpigmentation or scarring. Thirty-three percent achieved some lightening with IPL, 11% each for KTP and Nd:YAG, and 28% with further PDL pulses.

Third-Line Therapies

• Potassium titanyl phosphate laser	B
• Imiquimod (as antiangiogenic therapy)	B
• Photodynamic therapy	B
• Rapamycin (as antiangiogenic therapy)	B

Potassium titanyl phosphate laser treatment of resistant port-wine stains

Chowdhury MU, Harris S, Lanigan SW. *Br J Dermatol* 2001; 144: 814–7.

A greater than 50% reduction was seen in 17% of 30 patients with PWS previously treated by PDL; 20% of patients experienced side effects, including scarring or hyperpigmentation.

Treatment of PWS with KTP laser is advocated by some, although studies have shown it to have limited utility and an increased incidence of scarring.

Pilot study examining the combined use of pulsed dye laser and topical imiquimod versus laser alone for treatment of port wine stain birthmarks

Chang CJ, Hsiao YC, Mihm MC Jr, Nelson JS. *Lasers Surg Med* 2008; 40: 605–10.

This retrospective review of 20 Asian subjects (aged 3–56 years) with PWS used three test sites on each subject for treatment assignments to the following regimens: (1) PDL + imiquimod; (2) PDL

alone; and (3) imiquimod alone. PDL sites were treated once with a 585-nm wavelength, 10 J/cm² fluence, 1.5-ms pulse duration, and 7-mm spot size, with cryogen spray cooling. For the PDL + imiquimod and imiquimod-alone test sites, subjects applied imiquimod topically once a day for 1 month after PDL exposure or alone. Subjects were followed at 1, 3, 6, and 12 months after PDL exposure to evaluate all three test sites. The primary efficacy measurement was the quantitative assessment of blanching responses as measured by a DermoSpectrometer to calculate the hemoglobin index of each site at follow-up visits after PDL exposure. The authors report statistically significant differences in blanching responses over time favoring PDL + imiquimod compared with either PDL alone or imiquimod alone. Some evidence of redarkening, thought to be related to revascularization of blood vessels, was noted at 12 months at test sites treated with PDL + imiquimod and PDL alone. Transient hyperpigmentation was noted but had resolved on all sites without medical intervention within 6 months. The authors note that clinical validation in larger patient samples is necessary.

Enhanced port-wine stain lightening achieved with combined treatment of selective photothermolysis and imiquimod

Tremaine AM, Armstrong J, Huang YC, Elkeeb L, Ortiz A, Harris R, et al. *J Am Acad Dermatol* 2012; 66: 634–41.

Twenty-four patients with PWS were treated with PDL and randomized to apply posttreatment placebo cream or imiquimod 5% cream for 8 weeks. Chromameter measurements were taken at baseline and compared with measurements taken 8 weeks posttreatment. The change in erythema and the change in color between normal-appearing skin and PWS skin were the primary end points. Greater reduction in erythema and greater color improvement were noted with imiquimod. The authors note that the true clinical duration of effect is unknown. Minor skin irritation and other adverse events were noted.

Photodynamic therapy of port-wine stains: long-term efficacy and complication in Chinese patients

Xiao Q, Li Q, Yuan KH, Cheng B. *J Dermatol* 2011; 38: 1146–52.

The authors profess that PDL is not suitable for PWS patients with Fitzpatrick skin type V or with nodular lesions. In this retrospective study, the authors studied 642 Chinese patients who had received

PDT in a 5-year period (totaling 3066 treatment sessions; average of 2.6–8.2 sessions per patient). Seventy percent of patients had more than 25% clearing, and over 5% of patients had complete clearing. Ten percent of patients experienced complications that included hyperpigmentation (4.3%), scabbing (2.2%), blistering (1.4%), hypopigmentation (1.2%), prolonged blistering that persisted for >2 months (<0.7%), photoallergy (0.6%), and eczematous dermatitis (0.4%).

Topical rapamycin combined with pulse dye laser in the treatment of capillary vascular malformations in Sturge-Weber syndrome: phase II, randomized, double-blind, intraindividual placebo-controlled clinical trial

Marques L, Nunez-Cordoba JM, Aquado L, Pretel M, Boixeda P, Naqore E, et al. J Am Acad Dermatol 2014; 72: 151–8.

In 23 patients with SWS and facial PWS, four interventions were evaluated: placebo, PDL + placebo, rapamycin, and PDL + rapamycin. PDL + rapamycin showed a statistically significant improvement visually subjectively per patient and had a lower percentage of vessels in histologic analysis.

Topical daily treatment with 1% rapamycin cream after laser treatment may improve responsiveness to laser therapy by decreasing vascular proliferation.

Postinflammatory hyperpigmentation and other disorders of hyperpigmentation

Seemal Desai

Pigmentary disorders are among the most common conditions encountered in dermatologic practice. They may be due to increased activity of melanocytes or proliferation of the latter. The spectrum includes both congenital and acquired conditions. The latter can further be divided into localized dermatoses such as postinflammatory hyperpigmentation, melasma, etc., or generalized dermatoses such as those seen secondary to malignancy, metabolic disorders, autoimmune diseases, etc. The conditions presenting with predominant epidermal hypermelanosis present clinically with brownish pigmentation, whereas those with dermal hypermelanosis present with slate gray-colored macules. This chapter describes some of these common acquired dermatoses and gives a brief overview of the treatment options available.

Postinflammatory Hyperpigmentation

It is a common acquired cause of hypermelanosis that results from cutaneous injury/inflammation. It is more commonly seen in patients with skin of color (Fitzpatrick skin type IV–VI) than Caucasians. The population with higher phototypes is believed to be more prone to postinflammatory hyperpigmentation due to higher epidermal melanin content. The resulting pigmentation is also more intense and prolonged. Overproduction of melanin after cutaneous inflammation has been suggested as the etiology of the pigmentation. Common disorders that lead to postinflammatory hyperpigmentation include acne, allergic reactions, insect bite, atopic dermatitis, cutaneous infection, hypersensitivity reaction, drug-induced cutaneous injury, papulosquamous disorders, etc. The increase in the activity of the melanocytes after the cutaneous insult is secondary to the release of cytokines, chemokines, and reactive oxygen species. These mediators of inflammation lead to increased activity of melanocytes and tyrosinase. After an insult, the pigment can also be released into the dermis by the basal keratinocytes. This pigment when phagocytosed by the dermal macrophages imparts a slate blue color to the skin, in contrast to the brownish color seen after epidermal hypermelanosis.

Freckles

Freckles are pigmented, tan-colored, tiny macules present over the

sun-exposed area of the face such as the nose and malar area. The pigmentation of the lesions varies according to the sun exposure. The lesions are more common among the light-skinned individuals. Light microscopy reveals increased pigmentation of the basal layer with normal number of melanocytes.

Lentigines

Lentigines present clinically similar to freckles but have a few differentiating features. The color of the lesion is unaffected by sun exposure in contrast to freckles (increased pigmentation noticed on sun exposure). The histopathology of the lesion reveals increased number of basal melanocytes. The most common type is lentigo simplex, also called a *simple lentigo*. The lesions present at birth or soon after. Sun exposure and medical diseases have no association with this type.

The “solar lentigo,” “old age spot,” or “senile freckles” present on sun-exposed parts of the body such as face, forearms, dorsa of hands, and bald scalp. With aging, basal cells containing lipofuscin bodies accumulate in the basal layer. With increased aging more and more aged cells accumulate and form a brown spot.

PUVA lentigo is commonly seen in patients undergoing PUVA therapy.

Ink spot lentigo, also called *sunburn lentigo*, is a result of sun exposure. The lesions are located over the shoulders and are indicators of increased risk of skin cancer.

Apart from the previously mentioned types, lentigines can be part of lentiginosis syndromes such as LEOPARD syndrome, Moynahan syndrome, Peutz–Jeghers syndrome, etc.

Melasma

Melasma is a common acquired disorder of pigmentation that is encountered in females of child-bearing age. It is derived from the Greek word *melas* meaning black. Melasma appearing in pregnancy is referred to as *chloasma*. It has also been reported in men and constitutes less than 10% of the cases. Although all races are affected, the highest incidence is seen among populations living in regions where there is intense ultraviolet light exposure such as in Latinos of

Caribbean origin, Asians, and African descendants. The etiology of melasma is multifactorial and includes both genetic factors and environmental influences. Exposure to sunlight, phototoxic drugs, pregnancy, oral contraceptives, thyroid dysfunction, and cosmetics are some of the environmental triggers that have been implicated in the pathogenesis. Ultraviolet light leads to melanocortin hormone stimulation in the melanocytes, which eventually leads to increase in melanogenesis. Recently the role of visible light has also been shown to play a role in the pathogenesis.

The lesions clinically consist of well-defined, brownish to tan-colored macules with irregular, serrated borders present over the facial convexities (forehead, cheek), neck, and forearm. Based on the clinical pattern three types have been described: the centrofacial pattern involving forehead, cheeks, chin, and upper lip; the malar type involving cheeks and lip; and the mandibular pattern involving the ramus of the mandible. Histologic examination reveals increased pigmentation of the epidermis and dermis with perivascular lymphohistiocytic infiltrate.

Periorbital Hyperpigmentation

It is a common complaint affecting both sexes and all races. It presents clinically as homogeneous areas of hyperpigmentation present around the eyes. The condition gets worse with age due to thinning of skin and loss of subcutaneous fat around the eyes. Periorbital melanosis can be secondary to an inflammatory process such as atopic/allergic dermatitis, fixed drug eruption, erythema dyschromicum perstans, etc. Other etiologic factors include dermal melanin deposition, superficial placement of blood vessels, and anatomic factors such as prominent lacrimal sulcus, loss of periorbital fat, edema, and chronic photodamage.

Riehl Melanosis

Riehl melanosis, also called *pigmented contact dermatitis*, is an acquired pigmentary anomaly presenting as grayish to brown areas of reticulate pigmentation over the forehead and temples. It is a photocontact dermatitis resulting from the use of photosensitizing chemicals such as coal tar, minoxidil, cosmetics, etc. Ultraviolet

radiation plays an important role by inducing a photoallergic reaction. Other photoexposed sites such as neck, forearm, and dorsa of hands are also frequently involved. Histologic examination reveals degeneration of the basal cell layer with pigment incontinence in the dermis and lymphohistiocytic infiltrate.

Phototoxic Dermatitis

It is a condition due to the reaction between a photosensitizing substance and ultraviolet radiation. The phototoxic substances implicated include systemic drugs, topically applied cosmetics, fragrances, and plants containing furocoumarins. The lesions may present as bullae and erythema in the acute stage and resolve to leave behind patches of hyperpigmentation. Berloque dermatitis is a condition resulting from the use of bergamot oil in fragrances and colognes. The pigmentation is present at the sites of application of perfumes such as the retroauricular area and sides of the neck. Histology of the lesions reveals increased melanin in the basal layer and dermal melanophages.

Erythema Dyschromicum Perstans

Erythema dyschromicum perstans, also called *ashy dermatosis* or *gray dermatosis*, is an acquired cause of hyperpigmentation presenting as brownish macules situated over the trunk, face, and extremities. It was first described by Ramirez, and it has been more commonly reported among the Latin American population. Etiology is unknown. Possible causative factors that have been implicated include oral ingestion of x-ray contrast media, hepatitis C infection, and environmental contaminants. The disease is more common among Hispanics, and there is no sexual predilection. The lesions are oval grayish-colored macules over the trunk and proximal extremities. The initial lesions have a raised erythematous border that disappears later. Histopathologic examination of the initial lesion shows vacuolization of the basal layer with mononuclear infiltrate in the dermis. Older lesions show only pigment incontinence.

Lichen Planus Pigmentosus

It is a variant of lichen planus reported from the Indian subcontinent and the Middle East. It presents with coalescing grayish macules present over the sun-exposed parts. The lesions clinically resemble erythema dyschromicum perstans but can be distinguished by lack of inflammatory border and presence of lesions in sun-exposed parts. Histology reveals basal layer degeneration, bandlike lymphohistiocytic infiltrate present in the dermis, and Civatte bodies.

Poikioderma of Civatte

Poikioderma is a term that clinically represents a triad of pigmentation, atrophy, and telangiectasia. It is mostly seen in fair-skinned middle-age to elderly females. Sun exposure has been implicated as one of the most important factors in its pathogenesis. The distribution of the lesions in sun-exposed areas also favors the role of actinic damage in its causation. Other causative factors include photosensitizing cosmetics and fragrances. Lesions clinically consist of reticulate pigmentation along with atrophy and telangiectasia present along the sides of the cheeks and neck. Sun-protected sites, such as below the chin, are often spared. Light microscopic examination of lesions reveals atrophy of the epidermis, degeneration of the basal layer, and pigment incontinence and lymphocytic infiltrate in the dermis.

Management Strategy

The diagnosis of these hyperpigmentary dermatoses is often clinical; the need for a thorough history and examination cannot be underestimated. The age at onset, progression of lesions, characteristics and distribution of the lesions, and any preceding cutaneous lesion should be noted. History of drug intake, any systemic disorder, and hormonal abnormality should be ruled out before beginning treatment. Detailed history regarding the use of fragrances and cosmetics is essential to reach a correct diagnosis. Histopathology and dermoscopy may aid when the diagnosis is unclear.

Many compounds are available for the treatment of hypermelanosis. The selection of a therapeutic option is dependent on a number of factors such as past treatment taken, the therapeutic response reported, sensitivity of skin, Fitzpatrick skin type, etc. The

role of sun protection cannot be underestimated in the treatment of pigmentation disorders. Patients with Fitzpatrick skin types IV to V who are exposed to high ultraviolet radiation particularly benefit by the use of sunscreens. Sunscreen with a broad spectrum of sun protection is pivotal in the prevention and treatment of these disorders. Physical sunscreens containing zinc oxide and titanium oxide are preferred over the chemical sunscreens, which carry a risk of allergic contact dermatitis. Physical sunscreens are also cosmetically more acceptable as they cause less exothermic reaction and thus are more suitable for patients living in hot and humid conditions.

Evaluation of the effectiveness of a broad-spectrum sunscreen in the prevention of chloasma in pregnant women

Lakhdar H, Zouhair K, Khadir K, Essari A, Richard A, Seit   S, et al. J Eur Acad Dermatol Venereol 2007; 21: 738–42.

Two hundred women older than 18 years and less than 3 months pregnant were included in the study. Patients were prescribed sunscreen (SPF 50+, UVA-PF 28) every 2 hours. Participants were advised to avoid sunlight, heat, scrubbing, rubbing, and use of photosensitizing products. Follow-up was done at 3, 6, and 9 months. A total of 185 patients completed the study. Evaluation was done by the patient and the dermatologist (colorimetric evaluation) at each follow-up visit. Among the 185 patients completing the study 38% finished with lighter skin, 21% with darker, and 41% unchanged. Only five new cases of chloasma were noted among the total 185 participants at the end of the study corresponding to 2.7%, and only two cases reported worsening of existing melasma. The study demonstrated an effective role of the use of broad-spectrum sunscreen in the prevention of chloasma during pregnancy.

Recently the role of visible light in the pathogenesis of melasma has been stressed. Wavelength in the visible spectrum interferes with the action of depigmenting agents and increases risk of relapses posttreatment. It has been shown to increase inflammatory response after sun exposure, increasing the neutrophil and macrophage infiltration. Visible light increases the sun-induced photodamage and induces cell vacuolization and melanocytic response. It also makes the cells more susceptible to damage by solar radiation.

The treatment of all hyperpigmentation disorders includes a common group of depigmenting agents ([Table 200.1](#)). The prototype

drug is hydroquinone and is considered the gold standard, although it is not available everywhere. The efficacy of any new depigmenting agent is compared with hydroquinone.

First-Line Therapies

- 4% hydroquinone
- Hydroquinone plus other depigmenting agent
- Hydroquinone allergy/long-term use: arbutin, kojic acid, azelaic acid

A randomized controlled trial of the efficacy and safety of a fixed triple combination (fluocinolone acetonide 0.01%, hydroquinone 4%, tretinoin 0.05%) compared with hydroquinone 4% cream in Asian patients with moderate to severe melasma

Chan R, Park KC, Lee MH, Lee ES, Chang SE, Leow YH, et al. Br J Dermatol 2008; 159: 697–703.

This was a multicenter trial in nine centers (Korea, Philippines, Singapore, and Hong Kong) on 260 Southeast Asian patients with melasma. The study population was randomized into two groups: one group received triple combination (fluocinolone acetonide 0.01%, hydroquinone 4%, tretinoin 0.05%) and the other 4% hydroquinone for a total of 8 weeks. A questionnaire-based assessment for patient satisfaction was done. The participants in the triple combination group reported significantly more improvement (71%) compared with the hydroquinone group (50%) (p value = 0.005). Physician-reported improvement using static global assessment score confirmed those results. Significantly more patients in the triple combination group (87/125) reported a score of 0 (clear) or 1 (mild hyperpigmentation) compared with the 4% hydroquinone group (57/129). The triple combination group reported earlier onset of response with significant differences in score from 4 weeks onward. The cutaneous side effects reported such as erythema, itching, and discomfort were significantly more in the triple combination group compared with the hydroquinone group. An assessment was also made among the participants on how much they were bothered by the treatment side effects. A total of 43% of patients in the triple combination group were not bothered by treatment side effects compared with 77% (significantly more) in the hydroquinone group.

Efficacy and safety of a new triple-combination agent for the treatment of facial melasma

Taylor SC, Torok H, Jones T, Lowe N, Rich P, Tschen E, et al. *Cutis* 2003; 72: 67–72.

Table 200.1

Mechanism of action of commonly used hypopigmenting agents

Mechanism of action	Hypopigmenting agent
Tyrosinase inhibition	Hydroquinone Kojic acid Arbutin Azelaic acid Licorice Ellagic acid Flavonoids
Reactive oxygen scavengers	Ascorbic acid
Skin turnover acceleration	Retinoic acid Lactic acid Glycolic acid Salicylic acid
Inhibition of melanosome transfer	Niacinamide Soya/milk extracts
Prostaglandin inhibition	Tranexamic acid

Participants (641) were randomly divided into four groups: triple combination cream (4% hydroquinone, tretinoin 0.05%, and fluocinolone acetonide 0.01%; $n = 161$), dual combination agent (tretinoin 0.05% and 4% hydroquinone; $n = 158$), dual combination agent (tretinoin 0.05% and fluocinolone acetonide 0.01%; $n = 161$), or dual combination agent (4% hydroquinone and fluocinolone acetonide 0.01%; $n = 161$), each applied daily at night for 8 weeks. Of those receiving the triple combination cream, 26.1% had complete clearing of melasma compared with 9.5%, 1.9%, and 2.5%, respectively, in each of the dual combination creams. Side effects were more common in the tretinoin hydroquinone group (80%) followed by tretinoin fluocinolone acetonide (65%) group, triple combination (63%) group, and hydroquinone fluocinolone group (34%).

Hydroquinone has been extensively used to treat hypermelanosis. It is used in 2% to 4% concentration as either monotherapy or in combination with other agents. Effect becomes evident after 5 to 7 weeks; treatment can be continued for 1 year. Short-term side effects include erythema and burning, whereas long-term effects include ochronosis and confetti-like depigmentation. It is a strong oxidant and gets rapidly converted into melanocyte-toxic products, which are responsible for depigmentation caused

by the product. Recently concern has been raised regarding the long-term use of hydroquinone after reports of its carcinogenicity potential in rodents that were fed high doses of hydroquinone. Regulatory agencies in Europe, Japan, and the United States have banned its use in cosmetic preparations and over-the-counter products. However, over the 40 to 50 years of experience with this product for medical purposes, not a single report of malignancy was documented.

Azelaic acid 20% cream in the treatment of facial hyperpigmentation in darker skinned patients

Lowe NJ, Rizk D, Grimes P, Billips M, Pincus S. Clin Ther 1998; 20: 945–59.

A double-blind, randomized, vehicle-controlled trial in which 52 patients (Fitzpatrick skin types IV–VI) of melasma and postinflammatory hyperpigmentation were evaluated to determine the efficacy and safety of 20% azelaic acid cream. Results were evaluated at the end of 24 weeks. The group receiving azelaic acid showed a greater decrease in pigment intensity versus the other group. Results were evaluated using investigators' subjective scale ($p = 0.021$) and chromometric analysis ($p < 0.039$). Side effects reported were mild.

There is a growing need for nonhydroquinone-based, natural, efficacious, and safe skin-lightening agents. These agents selectively target hyperactive melanocytes and inhibit key enzymes in the melanogenic pathway. A combination of multiple ingredients is often used to increase effectiveness. However, large-scale clinical trials are lacking for most of the botanical agents to substantiate their claims of effectiveness.

Second-Line Therapies

- Chemical peels
- Laser
- Light therapy
- Microdermabrasion

Comparison of 30% salicylic acid with Jessner's solution for superficial chemical peeling in epidermal melasma

Ejaz A, Raza N, Iftikhar N, Muzzafar F. J Coll Physicians Surg Pak 2008; 18: 205–8.

A trial conducted in Pakistan to compare Jessner peel (14% salicylic acid, 14% lactic acid and 14% resorcinol) to 30% salicylic acid peel after priming with 0.05% tretinoin for 2 weeks nightly. Sixty patients were randomized into two groups; each group underwent fortnightly peeling sessions with either Jessner or salicylic acid peel for a total duration of 12 weeks. Total contact time was 5 min. Participants were followed up for 12 weeks after treatment discontinuation. No significant difference in the reduction of melasma was noted at the end of 12 or 24 weeks. Eight of 34 participants in the Jessner group reported adverse events compared with 10/26 in the salicylic acid group. The side effects reported included crusting, pigmentation, sunburn, and acneiform eruption. Three patients did not follow up after 12 weeks, and 14 patients did not follow up after 24 weeks.

Chemical peels cause controlled exfoliation of the epidermis. Superficial and medium-depth peels are used for treatment of pigmentation. Prolonged use of medium-depth peels carries a risk of dyschromia, especially in dark-skinned individuals. Choosing the right patient with adequate priming, strict sun protection, and concomitant topical therapy forms the backbone of a good peeling regimen.

Successful treatment of melasma using a combination of microdermabrasion and Q-switched Nd:YAG lasers

Kauvar AN. Lasers Surg Med 2012; 44: 117–24.

In this study, 27 female patients with melasma refractory to conventional therapy were treated with Nd:YAG laser session after microdermabrasion. Low-fluence laser treatment was used with 5- to 6-mm spot size and energy of 1.6 to 2 J/cm². Postprocedure, patients were discharged on sunscreen and topical preparation containing hydroquinone with tretinoin or vitamin C. Treatment was repeated at monthly intervals. About 50% of the patients reported improvement after 1 month of starting the treatment. Remission was noted for 6 months. Side effects reported included mild postprocedural erythema and exacerbation of lesions, which resolved in a few weeks after topical treatment.

Q-switched, fractional, IPL, and combination lasers are used in the treatment of pigmentary dermatosis with variable results. Individuals with higher Fitzpatrick skin types carry a risk of postinflammatory hyperpigmentation after the procedure. Other side effects reported include rebound hyperpigmentation, physical urticaria, acneiform eruption, etc.

Pregnancy dermatoses

Lauren E. Wiznia, and Miriam Keltz Pomeranz

Dermatoses specifically associated with pregnancy and the puerperium include polymorphic eruption of pregnancy, pemphigoid gestationis (PG), intrahepatic cholestasis of pregnancy, and atopic eruption of pregnancy. In addition to these classic dermatoses of pregnancy, pregnant women can develop all of the same pruritic dermatoses as nonpregnant women. There are also many skin changes during pregnancy that are normal physiologic changes.

Because some pregnancy-related dermatoses may adversely affect the fetus, it is important to correctly diagnose and treat these diseases. Pustular psoriasis of pregnancy (previously impetigo herpetiformis), which we will not address in this chapter as it is discussed elsewhere, can have a detrimental effect on pregnancy outcome as well.

Polymorphic Eruption of Pregnancy

Polymorphic eruption of pregnancy (PEP), also known as *pruritic urticarial papules and plaques of pregnancy (PUPPP)*, is an intensely pruritic dermatosis that usually begins in the third trimester of first pregnancies or in the immediate postpartum period. Pruritic urticarial papules are often the initial lesions. The immediate periumbilical area, face, palms, and soles are commonly uninvolved. Many patients develop polymorphic lesions, including erythema, vesicles, target lesions, and eczematous plaques. PEP tends not to recur in subsequent pregnancies.

Management Strategy

PEP has no increased risk of fetal or maternal morbidity, and the eruption resolves over an average of 4 weeks or within a few days of delivery. Treatment is often required to provide relief from intense itching. If pemphigoid gestationis is in the clinical differential, then consider a perilesional biopsy for direct immunofluorescence microscopy, which has nonspecific patterns in PEP (but is pathognomonic in pemphigoid gestationis). Contact dermatitis, drug eruptions, erythema multiforme, insect bites, and urticaria should be considered in the differential diagnosis.

In women with localized disease, application of *midstrength topical corticosteroids* provides symptomatic relief in most cases. Most patients benefit from emollients and topical antipruritics with additives such as menthol. Treatment should be initiated with lower strength corticosteroids and escalated to a higher strength if the patient is not responding adequately. Use of clobetasol should not exceed 300 grams during the course of a pregnancy. As the pregnancy continues, many patients require therapy only once a day or can stop treatment before delivery.

Oral first-generation H₁ antihistamines may offer some benefit in

severely pruritic patients at bedtime. Hydroxyzine is avoided because of an increased risk (5.8%) of congenital anomalies.

In more widespread cases and those that do not respond adequately to topical corticosteroids, a systemic corticosteroid treatment may be considered. *Oral prednisone or prednisolone 40 mg daily* or less over a taper of 1 to 2 weeks is very effective. Currently, PEP is not considered an indication for early delivery.

Specific Investigations (only if PG is being considered)

- Biopsy for direct immunofluorescence (DIF)
- Serum for indirect immunofluorescence (IIF) or ELISA BP 180

A prospective study of 200 women with dermatoses of pregnancy correlating clinical findings with hormonal and immunopathological profiles

Vaughan Jones SA, Hern S, Nelson-Piercy C, Seed PT, Black MM. *Br J Dermatol* 1999; 141: 71–81.

A prospective study of 200 women with dermatoses of pregnancy, 44 of whom had PEP. IIF was negative in all 44 cases of PEP, and DIF showed nonspecific findings. The most common histopathologic features on lesional skin biopsy were papillary dermal edema and a perivascular infiltrate, often with numerous eosinophils. Epidermal changes were common, with focal spongiosis and, less frequently, parakeratosis or hyperkeratosis.

Usefulness of BP180 NC16a enzyme-linked immunosorbent assay in the serodiagnosis of pemphigoid gestationis and in differentiating between pemphigoid gestationis and pruritic urticarial papules and plaques of pregnancy

Powell AM, Sakuma-Oyama Y, Oyama N, Albert S, Bhogal B, Kaneko F, et al. *Arch Dermatol* 2006; 141: 705–10.

A study of 412 women, 82 with PG and 164 with PEP and 166 age- and sex-matched controls, demonstrated that the NC16a ELISA is 96% sensitive and specific in differentiating PG from PEP.

First-Line Therapies

• Topical corticosteroids	D
• Antihistamines	D

Pruritic urticarial papules and plaques of pregnancy. Clinical experience in 25 patients

Yancey KB, Hall RP, Lawley TJ. J Am Acad Dermatol 1984; 10: 473–80.

Of 25 patients, 22 were successfully treated with frequent applications of high-potency topical corticosteroids, providing relief from pruritus and controlling the eruption. Three patients were treated with brief courses of systemic corticosteroids, ranging from 10 to 40 mg daily. Seven patients self-administered antihistamines or received them from referring physicians; two used cocoa butter, one used calamine lotion, and one used emollients; the authors noted that these agents were unsuccessful in controlling pruritus and lesion formation.

Pruritic urticarial papules and plaques of pregnancy (PUPPP). A clinicopathologic study

Callen JP, Hanno R. J Am Acad Dermatol 1981; 5: 401–5.

Of 15 cases, PEP cleared before delivery (5 cases), within 1 week of delivery (9 cases), and at 6 weeks postpartum (1 case). Treatment included various potent topical corticosteroids and diphenhydramine in all cases except one.

Safety of topical corticosteroids in pregnancy

Chi CC, Wang SH, Wojnarowska F, Kirtschig G, Davies E, Bennett C. Cochrane Database Syst Rev 2015; 10: CD007346.

A Cochrane review that assessed the effects of topical corticosteroids in pregnant women on pregnancy outcomes identified a probable association between low birth weight and maternal use of potent to very potent topical steroids, especially with very large cumulative dosage. Maternal exposure to topical corticosteroids of

any potency was not associated with an increase in adverse pregnancy outcomes, including mode of delivery, congenital abnormality, preterm delivery, fetal death, or low Apgar score.

Safety of dermatologic medications in pregnancy and lactation: part I. Pregnancy

Murase JE, Heller MM, Butler DC. J Am Acad Dermatol 2014; 70: 401.e1–14.

Fetal growth restriction has been reported with potent topical steroid use during the third trimester, particularly when using >300 grams. Guidelines recommend mild to moderate over potent corticosteroids, which should be used only for short periods. First-generation antihistamines are preferred over second-generation. Among second-generation antihistamines, loratadine remains first and cetirizine second choice. Hydroxyzine is avoided because of an increased risk (5.8%) of congenital anomalies. Antihistamine use within 2 weeks of delivery in neonates born prematurely has been reported to double the risk of retinopathy of prematurity (previously retrolental fibroplasia). Overdose and intravenous use of antihistamines can stimulate uterine contractions and increase the risk of fetal hypoxia.

Polymorphic eruption of pregnancy: clinicopathology and potential trigger factors in 181 patients

Rudolph CM, Al-Fares S, Vaughan-Jones SA, Müllegger RR, Kerl H, Black MM. Br J Dermatol 2006; 154: 54–60.

A retrospective analysis of 181 patients with PEP reported symptoms to be controlled in most patients with emollients and topical steroids. Systemic therapy with antihistamines was required in 25%. Systemic corticosteroids (prednisone and prednisolone) were required in 9%.

Second-Line Therapy

• Systemic corticosteroids

D

Pruritic urticarial papules and plaques of pregnancy. Clinical experience in twenty-five patients

Yancey KB, Hall RP, Lawley TJ. J Am Acad Dermatol 1984; 10: 473–80.

Please see previous section for discussion of systemic corticosteroid use.

Polymorphic eruption of pregnancy: clinicopathology and potential trigger factors in 181 patients

Rudolph CM, Al-Fares S, Vaughan-Jones SA, Müllegger RR, Kerl H, Black MM. Br J Dermatol 2006; 154: 54–60.

Please see previous section for discussion of systemic corticosteroid use.

Although only a limited number of severe cases of PEP that required oral corticosteroids are reported in the literature, it is generally accepted that this treatment is effective and safe if prednisone or prednisolone are chosen and used in the third trimester. However, larger series and prospective studies are lacking.

Pemphigoid Gestationis

PG, previously herpes gestationis, is a rare dermatosis of pregnancy seen in 1 in 1700 to 1 in 50,000 pregnancies. It presents with urticarial followed by vesicular lesions on the trunk and extremities in mid- to late pregnancy or the early postpartum period. It occurs in the presence of paternally derived tissue (fetus, hydatidiform mole, or choriocarcinoma). Unlike PEP, PG involves periumbilical skin.

Management Strategy

An important part of managing PG is making the diagnosis. Patients in whom PG is suspected usually require biopsy for histology and DIF. DIF with C3 in a linear band at the dermal–epidermal junction is pathognomonic for PG. Circulating autoantibodies are directed against the same target antigens as in bullous pemphigoid, more commonly against BP180 than BP230. The ELISA can be sent (with specificity and sensitivity as high as 96%) or, if available, IIF studies for the BP180 antigen.

Treatment can begin with topical steroids and a systemic antihistamine. First-generation antihistamines are favored over

second-generation (see also discussion earlier about the use of antihistamines in PEP). Most patients require *systemic corticosteroid* treatment. Initially doses of prednisolone or its equivalent in the range of ½ mg/kg body weight may be tried, but in severe cases, 1 mg/kg of prednisolone may be necessary.

Many women will improve and may decrease doses of or even discontinue steroids. In cases that do not respond satisfactorily to prednisolone alone or in cases where prolonged treatment with corticosteroids is contraindicated, plasmapheresis or intravenous immunoglobulins may be considered.

The maternal prognosis is very good, with most cases resolving within a few months postpartum; however, it may take weeks, months, or even years until complete remission; 75% of women flare postpartum, requiring treatment. Exacerbations may occur postpartum with oral contraceptives and during the menstrual cycle. PG often recurs and is commonly more severe in subsequent pregnancies.

Newborns of mothers with PG may develop bullous lesions, which are transient and require no therapy. PG is associated with premature delivery and a risk of low birth weight, and the risk of these fetal complications correlates with maternal disease severity. Therefore patients with PG should be followed more carefully by the obstetrician.

Specific Investigations

- Biopsy for histopathology and DIF
- Serum for enzyme-linked immunosorbent assay (immunoblot) and/or IIF

Clinical and immunologic profiles of 25 patients with pemphigoid gestationis

Tani N, Kimura Y, Koga H, Kawakami T, Ohata C, Ishii N, et al. Br J Derm 2015; 172: 120–9.

Clinical and immunologic profiles were performed on 25 patients with PG. DIF showed C3 deposition in the basement membrane zone in all patients, and IIF revealed circulating IgG anti-basement membrane zone autoantibodies in 92% of patients. Immunoblotting and ELISA of the NC16a domain of BP180 recombinant protein were

positive in 96% and 92% of patients, respectively. Only 4 patients had a positive ELISA for BP230.

First-Line Therapies

• Topical corticosteroids	D
• Systemic corticosteroids	D
• Antihistamines	D

Clinical features and management of 87 patients with pemphigoid gestationis

Jenkins RE, Hern S, Black MM. Clin Exp Dermatol 1999; 24: 255–9.

A review of 142 pregnancies in 87 patients with PG. Only 69 patients had documented treatment information. Thirteen of these 69 patients (18.8%) were treated with topical corticosteroids without systemic therapy. Chlorpheniramine suppressed pruritus in most patients. Fifty-six out of 69 (81.2%) required systemic corticosteroids with initial doses of prednisolone of 5 to 110 mg daily, with suppression of blistering in most patients. Two patients' eruptions were not controlled with high-dose systemic corticosteroids, with disease persistence for more than 10 years.

Pregnancy outcome after first trimester exposure to corticosteroids: a prospective controlled study

Gur C, Diav-Citrin O, Shechtman S, Arnon J, Ornoy A. Reprod Toxicol 2004; 18: 93–101.

This study, which was powered to find a 2.5-fold increase in teratogenicity, supports that glucocorticosteroids do not represent a major teratogenic risk in humans.

Second-Line Therapies

• Plasmapheresis	E
• High-dose intravenous immunoglobulin (IVIG)	E

Plasma exchange in herpes gestationis

Van de Wiel A, Hart HC, Flinterman J, Kerckhaert JA, Du Boeuff JA, Imhof JW. Br Med J 1980; 281: 1041–2.

A case report of a 40-year-old patient with PG initially treated with antihistamines and pyridoxine, both of which were ineffective. Systemic corticosteroid treatment was thought inadvisable, and the patient received three exchanges during the twenty-sixth week of pregnancy. Within 24 hours of the first exchange, the patient's pruritus subsided and no new lesions developed. After three exchanges, the lesions had largely resolved. After delivery, an exacerbation occurred that required four additional exchanges within 1 week. A flare 3 weeks postpartum required two more exchanges.

Successful treatment of a severe persistent case of pemphigoid gestationis with antepartum and postpartum intravenous immunoglobulin followed by azathioprine

Gan DC, Wels B, Webster M. Australas J Dermatol 2012; 53: 66–9.

A case of PG affecting a 37-year-old patient in both of her pregnancies. The patient failed to respond to high-dose oral prednisone in her second pregnancy. She was treated successfully with IVIG (2 g/kg each infusion cycle), both during the antepartum and postpartum period. After ceasing IVIG, azathioprine (up to 1 mg/kg/day) was initiated for control.

Antepartum intravenous immunoglobulin therapy in refractory pemphigoid gestationis: case report and literature review

Doiron P, Pratt M. J Cutan Med Surg 2010; 14: 189–92.

A case report of a 34-year-old woman who developed PG with three pregnancies. The PG in her first two pregnancies was managed with oral prednisone and topical agents. PG in the patient's third pregnancy was initially treated with prednisone but ultimately required monthly infusions of IVIG. A healthy baby was delivered at 37.5 weeks.

Third-Line Therapies

• Azathioprine	E
• Cyclophosphamide	E
• Ciclosporin	E
• Dapsone	D
• Sulfapyridine	E
• Pyridoxine	E
• Rituximab	E

A severe persistent case of pemphigoid gestationis treated with intravenous immunoglobulin and cyclosporine

Hern S, Harman K, Bhogal BS, Black MM. Clin Exp Dermatol 1998; 23: 185–8.

A report of a patient with severe PG that persisted for 1.5 years postpartum. The patient was treated with prednisolone (initially at 80 mg daily) and two doses of IVIG (5-day course at 0.4 g/kg daily) and then required ciclosporin (initially at 100 mg and then tapered).

Chronic herpes gestationis and antiphospholipid antibody syndrome successfully treated with cyclophosphamide

Castle SP, Mather-Mondrey M, Bennion S, David-Bajar K, Huff C. J

Am Acad Dermatol 1996; 34: 333–6.

A report of a patient with PG treated postpartum with pulse-dose intravenous cyclophosphamide (1.245 g, 0.75 g/m²). The patient was initially treated at 19 weeks of gestation with oral prednisone with no effect; increasing dosages of prednisone were administered (up to 120 mg/day) with no effect. The patient continued to have lesions postpartum, despite continued oral prednisone. Azathioprine treatment was initiated 8 months postpartum but was discontinued within 1 month secondary to increased liver enzyme values. Pulsed intravenous cyclophosphamide was administered 9 months postpartum. The patient received two doses during a 2-month period with resolution of skin lesions and associated symptoms. A mild recurrence 5 months later was treated with an additional dose.

Cytotoxic agents such as cyclophosphamide for the treatment of PG can only be used in the postpartum period while the mother is not breastfeeding.

Clinical features and management of 87 patients with pemphigoid gestationis

Jenkins RE, Hern S, Black MM. Clin Exp Dermatol 1999; 24: 255–9.

A review of 142 pregnancies in 87 patients with PG. Azathioprine, dapsone, sulfapyridine, and pyridoxine were used as adjunctive therapy with oral corticosteroids (in 2, 6, 2, and 5 out of 56 patients, respectively).

Severe persistent pemphigoid gestationis: long-term remission with rituximab

Cianchini G, Masini C, Lupi F, Corona R, De Pita O, Puddu P. Br J Dermatol 2007; 157: 388–9.

A case report of a 31-year old woman who, during the fifth month of her third pregnancy, developed PG resistant to systemic corticosteroid therapy. A male infant was born at 32 weeks, 2 days, after which the patient flared. After 5 months of unsuccessful corticosteroid therapy with azathioprine daily, she was treated with dapsone for 3 months. IVIG was then initiated, followed by rituximab (375 mg/m² weekly for four consecutive weeks). Azathioprine was discontinued and prednisone tapered. Clinical remission lasted for 2 months, at which time another four infusions of rituximab (375 mg/m² at 2-month intervals) were given.

The benefit of these drugs on the course of the disease remains

questionable.

Intrahepatic Cholestasis of Pregnancy

Intrahepatic cholestasis of pregnancy (ICP, previously pruritus gravidarum and prurigo gravidarum) is a rare, reversible cholestasis that typically occurs in late pregnancy. Patients present with dramatic pruritus that may initially involve the palms and soles; jaundice can occur in 10% of patients. ICP is the only pregnancy dermatosis that presents without primary skin lesions. A reduced excretion of bile acids likely contributes to severe maternal pruritus that typically resolves soon after delivery. More concerning are harmful effects on the fetus, including an increase in premature births, intrapartum fetal distress, and fetal death.

Management Strategy

ICP must be differentiated from other causes of pruritus during pregnancy. The differential diagnosis can include scabies, eczema, urticaria, and drug eruptions, as well as early cases of PEP and PG. Total serum bile acid levels greater than 11 $\mu\text{mol/L}$ are consistent with ICP. Liver function tests may be abnormal as well, often with an elevated alkaline phosphatase. The maternal pruritus and cholestasis usually resolve within a few days of delivery. ICP may recur with subsequent pregnancies and oral contraceptive pill use.

First-line treatment includes *ursodeoxycholic acid* (either a dose of 15 mg/kg/day or, independent of body weight, 1 g/day is administered either as a single dose or divided into two or three doses until delivery), which is thought to correct the maternal serum bile acid profile, relieve symptoms, and improve fetal prognosis. Early delivery at 38 weeks or before is frequently advocated by obstetricians to reduce the risk of intrauterine fetal demise.

In mild disease, pruritus may improve with the adjuvant use of topical treatments such as *cooling lotions or creams* and antihistamines. *Phototherapy* may also be of benefit. These adjuvant treatments will not affect fetal outcome.

Specific Investigations

- Liver function tests, total serum bile acid
- Hepatitis C serologies

Specific pruritic disease of pregnancy. A prospective study of 3192 pregnant women

Roger D, Vaillant L, Fignon A, Pierre F, Bacq Y, Brechot JF, et al. Arch Dermatol 1994; 130: 734–9.

A prospective study of pregnant women presenting with pruritus identified 17 patients with ICP. The increase in mean values of alanine aminotransferase, aspartate aminotransferase, total serum bile salt, serum cholyglycine, serum 5'-nucleotidase, and total alkaline phosphatase was statistically significant compared with the control group.

Intrahepatic cholestasis of pregnancy: relationships between bile acid levels and fetal complication rates

Glantz A, Marschall HU, Mattsson LA. Hepatology 2004; 40: 287–8.

Prospective cohort study that identified 693 ICP cases. The probability of preterm delivery, asphyxia events, and green staining of placenta and membranes did not increase until bile acid levels exceeded 40 $\mu\text{mol/L}$, and the probability of meconium staining of amniotic fluid started to rise when bile acid levels exceeded 20 $\mu\text{mol/L}$.

The importance of serum bile acid level analysis and treatment with ursodeoxycholic acid in intrahepatic cholestasis of pregnancy: a case series from central Europe

Ambros-Rudolph CM, Glatz M, Trauner M, Kerl H, Müllegger RR. Arch Dermatol 2007; 143: 757–62.

A retrospective study of 13 patients with ICP reported elevated total serum bile acid levels in all patients. Pregnancies complicated by fetal distress or prematurity demonstrated higher total bile acid levels than those with normal fetal outcome. Other hepatic function test abnormalities were noted in 77% of patients, with elevated serum aspartate aminotransferase in 62%, alanine aminotransferase in 46%, gamma-glutamyl transferase in 23%, total serum bilirubin in 15%, and alkaline phosphatase in 100%.

Intrahepatic cholestasis of pregnancy in hepatitis C virus infection

Paternoster DM, Fabris F, Palu G, Santarossa C, Bracciante R, Snijders D, et al. *Acta Obstet Gynecol Scand* 2002; 81: 99–103.

A prospective study of the prevalence of hepatitis C virus infection and incidence of ICP reported 56 patients to have developed intrahepatic cholestasis of pregnancy (ICP), 12 of whom were HCV-RNA positive. ICP was observed more commonly in HCV-RNA-positive women than in HCV-RNA-negative women, leading the authors to conclude that ICP during the third trimester should prompt assessment of patients' HCV status.

Intrahepatic cholestasis of pregnancy: maternal and fetal outcomes associated with elevated bile acid levels

Brouwers L, Koster MP, Page-Christiaens GC, Kemperman H, Boon J, Evers IM, et al. *Am J Obstet Gynecol* 2015; 212: 100.e1.

A retrospective study of 215 ICP patients studied the correlation of bile acid levels and pregnancy outcome. The group was divided into mild (bile acid levels 10–39 $\mu\text{mol/L}$), moderate (40–99 $\mu\text{mol/L}$), and severe (≥ 100 $\mu\text{mol/L}$) ICP. Higher bile acid levels were significantly associated with spontaneous preterm birth, meconium-stained amniotic fluid, and perinatal death. Gestational age at diagnosis and delivery was significantly lower in the severe compared with the mild ICP group.

Fetal outcomes in pregnancies complicated by intrahepatic cholestasis of pregnancy in a Northern California cohort

Rook M, Vargas J, Caughey A, Bacchetti P, Rosenthal P, Bull L. *PLoS One* 2012; 7: e28343.

A study of 101 women with ICP reported fetal complications in 33% of deliveries, with respiratory distress accounting for the majority of complications. The study found no statistically significant clinical or biochemical predictors of increased risk of fetal complications.

First-Line Therapies

• Ursodeoxycholic acid (UDCA)	A
• Early delivery	D

Ursodeoxycholic acid in the treatment of cholestasis of pregnancy: a randomized, double-blind study controlled with placebo

Palma J, Reyes H, Ribalta J, Hernández I, Sandoval L, Almuna R, et al. J Hepatol 1997; 27: 1022–8.

A study of 24 patients with ICP detected before week 33 of pregnancy randomly assigned patients to receive UDCA or placebo until delivery. Of the 15 patients who completed the study, 8 received UDCA and 7 placebo. After 3 weeks of treatment, patients receiving UDCA had statistically significant improvements in pruritus, serum bilirubin, aspartate aminotransferase, and alanine aminotransferase. A nonstatistically significant decrease in serum total bile salts was noted. Patients treated with UDCA delivered at or near term compared with five of the seven patients treated with placebo who delivered before week 36 of pregnancy, including one stillbirth.

Ursodeoxycholic acid in the treatment of intrahepatic cholestasis of pregnancy. A 12-year experience

Zapata R, Sandoval L, Palma J, Hernandez I, Ribalta J, Reyes H, et al. Liver Int 2005; 25: 548–54.

A retrospective analysis of 32 ICP patients who received UDCA for at least 3 weeks before delivery and were compared with 16 historical controls. UDCA treatment decreased pruritus, serum bilirubin, ALT, and bile salt levels. Term delivery occurred in 65.7% of UDCA-treated patients compared with only 12.5% of the control group. Infants born to mothers treated with UDCA weighed a mean of 500 g more than those born to controls.

Efficacy of ursodeoxycholic acid in treating intrahepatic cholestasis of pregnancy: a meta-analysis

Bacq Y, Sentilhes L, Reyes HB, Glantz A, Kondrackiene J, Binder T, et al. Gastroenterology 2012; 143: 1492–1501.

A meta-analysis of nine randomized controlled trials comprising

data from 454 ICP patients compared the effects of UDCA to other drugs, placebo, or no specific treatment. UDCA was associated with reduced or resolved pruritus, normalization of liver function tests, fewer premature births, reduced fetal distress, less frequent respiratory distress syndrome, and fewer neonates in the intensive care unit in analyses of UDCA compared with all controls. In analyses of UDCA compared with placebo, UDCA reduced pruritus and normalized liver function tests.

Interventions for treating cholestasis in pregnancy

Gurung V, Middleton P, Milan SJ, Hague W, Thornton JG. Cochrane Database Syst Rev 2013; 6: CD000493.

A Cochrane review of randomized controlled trials compared intervention strategies for patients with ICP. Twenty-one trials involving 1197 women were included, with 11 different interventions resulting in 15 different comparisons. UDCA showed improvement in pruritus in 5 out of 7 trials. There were significantly fewer total preterm births with UDCA and fewer (although not statistically significant) instances of fetal distress/asphyxia events in the UDCA groups compared with placebo.

The risk of infant and fetal death by each additional week of expectant management in intrahepatic cholestasis of pregnancy by gestational age

Puljic A, Kim E, Page J, Esakoff T, Shaffer B, LaCoursiere DY, et al. Am J Obstet Gynecol 2015; 212: 667.e1.

A retrospective study of 1,604,386 singleton pregnancies of women between 34 and 40 weeks' gestation with and without ICP. Among women with ICP, the mortality risk of delivery is lower than the risk of expectant management at 36 weeks' gestation. The authors concluded that delivery at 36 weeks' gestation would reduce perinatal mortality risk compared with expectant management.

Primum non nocere: how active management became modus operandi for intrahepatic cholestasis of pregnancy

Henderson CE, Shah RR, Gottimukkala S, Ferreira KK, Hamaoui A, Mercado R. Am J Obstet Gynecol 2014; 211: 189–96.

To evaluate ICP as an indication for early term delivery, the authors divided 16 articles based on whether or not obstetric care included active management. They found no evidence to support active

management for ICP, noting that the stillbirth rates in both groups were similar to their respective national stillbirth rate.

Second-Line Therapies

• Phototherapy	E
• Emollients and topical antipruritic agents	D
• Antihistamines	D

Dermatoses of pregnancy

Shornick JK. Semin Cutan Med Surg 1998; 17: 172–81.

Review indicating that UVB phototherapy may be useful for symptomatic treatment of ICP.

Specific pruritic disease of pregnancy. A prospective study of 3192 pregnant women

Roger D, Vaillant L, Fignon A, Pierre F, Bacq Y, Brechot JF, et al. Arch Dermatol 1994; 130: 734–9.

A prospective study of pregnant women presenting with pruritus identified 17 patients with ICP. Thirteen patients received emollients and oral antihistamines. Pruritus resolved in all cases within 2 weeks of delivery.

Atopic Eruption of Pregnancy

Atopic eruption of pregnancy (AEP, previously prurigo of pregnancy, prurigo gestationis, early onset prurigo of pregnancy, pruritic folliculitis of pregnancy, and eczema in pregnancy) is the most common pregnancy dermatosis. It is a benign pruritic disorder that presents early in pregnancy (in 75% of patients before the third trimester) with eczematous and/or papular lesions in patients with an atopic diathesis. For approximately 80% of AEP patients, the eruption is the first occurrence of atopy, whereas it represents an exacerbation for the remaining 20%. AEP tends to recur in subsequent pregnancies.

Management Strategy

There are no fetal or maternal risks associated with AEP other than significant maternal pruritus. Topical corticosteroids with or without systemic antihistamines are often sufficient for resolution of lesions and improvement of pruritus. Emollients and topical antipruritic agents also play a role. Severe cases may require a short course of systemic corticosteroids and antihistamines, and secondary bacterial infections may require oral antibiotics. Phototherapy (UVB) is an additional option, particularly for severe cases in early pregnancy.

Specific Investigations

- None

The specific dermatoses of pregnancy revisited and reclassified: results of a retrospective two-center study on 505 pregnant patients

Ambros-Rudolph CM, Müllegger RR, Vaughan-Jones SA, Kerl H, Black MM. J Am Acad Dermatol 2006; 54: 395–404.

A retrospective study of 505 pregnant patients proposed a reclassification of eczema in pregnancy, prurigo of pregnancy, and pruritic folliculitis of pregnancy into the category of AEP.

First-Line Therapies

- Topical corticosteroids
- Antihistamines

For their use in pregnancy, see the discussion earlier in the section discussing PEP.

Second-Line Therapy

- UVB

The authors would like to acknowledge the work of the previous edition's contributor, Wolfgang Jurecka, MD.

Pretibial myxedema

Elizabeth R. Ghazi, and Warren R. Heymann

Pretibial myxedema, more accurately termed *thyroid dermopathy*, is characterized by nonpitting edema and skin-colored to violaceous nodules or plaques. These are most commonly distributed pretibially but can sometimes be seen over the arms, shoulders, head, and neck. The differential diagnosis of thyroid dermopathy includes lymphedema, lipodermatosclerosis, and the newly described *obesity-associated lymphedematous mucinosis*.

Management Strategy

Pretibial myxedema is an autoimmune phenomenon that tends to occur after treatment of patients with Graves disease. The condition can, however, develop in hypothyroid and euthyroid patients. It is helpful to look for other clinical signs of thyroid disease, including thyroid acropachy (characterized by clubbing of the fingers and toes, periosteal proliferation of the phalanges and long bones, and swelling of the soft tissue overlying bony structures) and the presence of a goiter. Pretibial myxedema typically follows the onset of ophthalmopathy, often years after the diagnosis of hyperthyroidism. Goals of treatment include cosmesis and the prevention of long-term side effects such as elephantiasis, decreased range of motion, or footdrop from neural entrapment. Resolution may occur without treatment.

Patients with significant thyroid dermopathy should be started on a trial of *high-potency topical corticosteroids*, alone or under occlusion, for at least 2 months. If symptoms persist, *intralesional corticosteroids* may be effective. A combination of these methods in conjunction with *compression bandages* can be beneficial when monotherapy proves inadequate. Both *oral* and *intravenous corticosteroids* have also been shown to improve lesions in several patients. However, their use is limited by systemic side effects.

Pentoxifylline, an analog of methylxanthine theobromine, has been shown to reduce the extent of lesions and can also be used in conjunction with topical and/or intralesional corticosteroids. Although there are conflicting data, the use of *intravenous immunoglobulin (IVIG)* may improve lesions of pretibial myxedema. Subcutaneous or intralesional *octreotide*, a somatostatin analog, yields conflicting results. *Plasmapheresis* has been reported to be beneficial in improving severe cases and has been successful when used in combination with rituximab.

Temporary improvement with *cytotoxic agents* has been observed. Pretibial myxedema is not a life-threatening condition, and so the use of such agents should be limited to severe, debilitating cases. *Surgical excision* has been shown to be effective in a minority of cases. The high risk of recurrence makes surgical intervention an infrequently used modality; however, postoperative intralesional steroids can minimize this risk. *Complete decongestive physiotherapy* has shown some success in treating the elephantiasic form of pretibial myxedema.

Pretibial ultrasonography, with or without digital infrared thermal imaging, to measure skin thickness may be useful in assessing treatment response. Measuring serum hyaluronic acid levels to follow therapeutic response may also be of value.

Specific Investigations

- Thyroid function tests
- Antithyroglobulin and antithyroid peroxidase antibodies
- Antithyroid-stimulating hormone receptor antibodies
- Pretibial ultrasound and/or digital infrared thermal imaging
- Serum hyaluronic acid

Pretibial myxedema

Fatourechi V. In: Heymann WR, ed. Thyroid Disorders with Cutaneous Manifestations. London: Springer Verlag 2008; 103–19.

Pretibial myxedema: case presentation and review of treatment options

Kim WB, Mistry N, Alavi A, Sibbald C, Sibbald RG. Int J Low Extrem Wounds 2014; 13: 152–4.

A classic case of pretibial myxedema in a 57-year-old woman treated for Graves disease is presented.

This article details how to differentiate pretibial myxedema from lymphedema and lipodermatosclerosis.

Pretibial myxedema as the initial manifestation of Graves' disease

Georgala S, Katoulis AC, Georgala C, Katoulis EC, Hatziolou E, Stavrianeas NG. J Eur Acad Dermatol Venereol 2002; 16: 380–3.

A 28-year-old Greek woman presented initially with asymptomatic pretibial myxedema, which ultimately led to a diagnosis of Graves disease. This patient had elevated anti-TSH-receptor antibodies.

An assessment of thyroid function is warranted because most patients with pretibial myxedema have clinical or laboratory evidence of autoimmune thyroid disease.

Observing pretibial myxedema in patients with Graves' disease using digital infrared thermal imaging and high-resolution

ultrasonography: for better records, early detection and further investigation

Shih SR, Lin MS, Li HY, Yang HY, Hsiao YL, Chang MT, et al. Eur J Endocrinol 2011; 164: 605–11.

Digital infrared thermal imaging (DITI) detects surface temperature, and sonography reflects composition changes in soft tissue. Lower leg temperatures of normal volunteers decreased gradually from proximal to distal parts. In all patients with pretibial myxedema, DITI showed abnormally low focal temperatures over the lesions. In Graves disease patients with mild diffuse nonpitting edema and Graves disease patients with normal appearance of lower legs, DITI showed abnormally low focal temperature in 90.9% and 65.2% of the patients, respectively. Areas of clinically visible pretibial myxedema and low focal temperature detected by DITI were sonographically characterized with increased skin thickness, hypoechoic substance deposition in the cutaneous tissue, and blurred boundary lines between dermis and subcutaneous tissue.

The use of DITI and high-resolution ultrasonography to analyze pretibial skin of patients with Graves disease allows for early detection of pretibial myxedema in patients with and without visible dermatopathy. We anticipate that newer technologies such as optical coherence tomography will also be utilized for assessing patients with thyroid dermatopathy.

First-Line Therapies

• Topical corticosteroids with or without occlusion	C
• Intralesional corticosteroids	D
• Compression	D

Dermopathy of Graves disease (pretibial myxedema): review of 150 cases

Fatourechi V, Pajouhi M, Fransway AF. Medicine 1994; 73: 1–7.

Treatment with topical 0.05% to 0.1% triamcinolone acetonide cream under occlusion for 2 to 10 weeks led to partial remission in 29 of 76 patients in this retrospective study; 1% had complete remission.

Treatment of pretibial myxedema with topical steroid ointment application with sealing cover in Graves' patients

Takasu N, Higa H, Kinjou Y. Intern Med 2010; 49: 665–9.

The authors detail their experience of six patients with pretibial myxedema treated with triamcinolone 0.1% under occlusion. Only two patients responded to therapy; these patients had their treatments initiated within months of the appearance of pretibial myxedema.

A delay in treatment of 5 to 10 years or advanced Graves disease manifested by exophthalmos may be associated with refractory disease when treated with topical steroids under occlusion.

Intralesional triamcinolone therapy for pretibial myxedema

Lang PG, Sisson JC, Lynch PJ. Arch Dermatol 1975; 111: 197–202.

Seven of nine patients treated with monthly injections of 8 mL or less of intralesional triamcinolone acetonide solution (5 mg/mL, 1 mL per injection site) had complete remission of pretibial myxedema after a total of three to seven visits. The other two patients, despite withdrawing from the study prematurely for nonmedical reasons, showed a partial improvement.

Pretibial myxedema: a review of the literature and case report

Frisch DR, Roth I. J Am Podiatr Med Assoc 1985; 75: 147–52.

A 29-year-old woman with pretibial myxedema was treated with rest, elevation, and topical 0.05% fluocinonide cream under occlusion. Outpatient therapy included weekly intralesional Celestone Soluspan injections followed by topical 0.05% fluocinonide cream under occlusion. Compression dressings with an Unna boot were applied weekly. After 2 months the lesions were greatly improved.

Compression stockings may also be beneficial. Unless contraindicated, compression should be used in conjunction with any therapeutic approach for this disorder.

Pretibial myxoedema with autoimmunity and hyperplasia treated with glucocorticoids and surgery

Lan C, Li C, Yang M, Mei X, He Z, Chen W, et al. Br J Dermatol 2012; 166: 457–9.

A patient with pretibial myxedema presenting as verruciform plaques failed initial treatment with monthly intralesional injections of 1 mL betamethasone, 0.2 mL at each of five points, but responded

when the injections were increased to every 2 weeks. A second patient with tumorous lesions responded to surgical removal of tumors with postoperative intralesional triamcinolone acetonide 10 mg at five points every 3 days as prophylaxis to prevent recurrence.

Second-Line Therapies

• Pentoxifylline	E
• Pentoxifylline with topical and/or intralesional steroid	E

Pentoxifylline inhibits the proliferation and glycosaminoglycan synthesis of cultured fibroblasts derived from patients with Graves' ophthalmopathy and pretibial myxedema

Chang CC, Chang TC, Kao SC, Kuo YF, Chien LF. Acta Endocrinol 1993; 129: 322–7.

Pentoxifylline caused an in vitro dose-dependent decrease in fibroblast proliferation and glycosaminoglycan synthesis in fibroblast cultures taken from pretibial sites. A preliminary trial with a dose of 400 mg intravenously and 800 mg orally daily of pentoxifylline reduced the size of pretibial myxedema lesions within 1 week.

Successful combined pentoxifylline and intralesional triamcinolone acetonide treatment of severe pretibial myxedema

Engin B, Gumusel M, Ozdemir M, Cakir M. Dermatol Online J 2007; 13: 16.

A 32-year-old man achieved partial remission with clobetasol under occlusion combined with pentoxifylline 400 mg three times daily and intralesional triamcinolone (5 mg/mL).

Third-Line Therapies

• Intravenous immunoglobulin	D
• Systemic corticosteroids (including pulse corticosteroid therapy)	D
• Octreotide	E
• Plasmapheresis	D
• Plasmapheresis with rituximab	E
• Cytotoxic therapy	E
• Surgery	E
• Complete decongestive physiotherapy	E
• UVA1 in combination with topical and intralesional steroids	D
• Radiotherapy	E

Pretibial myxedema and high-dose intravenous immunoglobulin treatment

Antonelli A, Navarranne A, Palla R, Alberti B, Saracino A, Mestre C, et al. *Thyroid* 1994; 4: 399–408.

Improvement of pretibial myxedema began after a few weeks in six patients treated with 400 mg/kg daily of high-dose IVIG given over 3 to 4 hours on 5 consecutive days. The cycle was repeated three times every 21 days. Maintenance therapy of 400 mg/kg for 1 day was then administered for 7 to 15 more cycles every 21 days. Total treatment ranged from 7 to 12 months, with maximum response occurring after an average of 6 months.

Lack of response of elephantiasic pretibial myxoedema to treatment with high-dose intravenous immunoglobulins

Terheydem P, Kahaly GJ, Zillikens D, Brocker EB. *Clin Exp Dermatol* 2003; 28: 224–6.

IVIG did not significantly improve the lesions of a patient with elephantiasic pretibial myxedema.

Corticoid therapy for pretibial myxedema: observations on the long-acting thyroid stimulator

Benoit FL, Greenspan FS. *Ann Intern Med* 1967; 66: 711–20.

Oral prednisolone, begun at 60 mg and then tapered, and methylprednisolone starting at 40 mg cleared the pretibial lesions of

four patients and improved the lesions of two others. Of the various corticosteroid treatments studied, the best results were obtained with high-dose systemic corticosteroids for 2 weeks.

Refractory pretibial myxoedema with response to intralesional insulin-like growth factor 1 antagonist (octreotide): downregulation of hyaluronic acid production by the lesional fibroblasts

Shinohara M, Hamasaki Y, Katayana I. Br J Dermatol 2000; 143: 1083–6.

Intralesional octreotide 200 µg daily improved the lesions of pretibial myxedema in a male patient with Graves disease after 4 weeks of therapy.

Octreotide inhibits insulin-like growth factor-1–induced hyaluronic acid secretion by lesional fibroblasts, which may play a role in the pathogenesis of pretibial myxedema.

Octreotide and Graves' ophthalmopathy and pretibial myxoedema

Chang TC, Kao SC, Huang KM. Br Med J 1992; 304: 158.

Three patients with pretibial myxedema were successfully treated with 100 µg of octreotide three times daily.

The authors do not comment on the route of administration of the octreotide acetate. According to the Physicians' Desk Reference, the drug may be administered either by subcutaneous injection or intravenously.

Lack of effect of long-term octreotide therapy in severe thyroid-associated dermatopathy

Rotman-Pikielny P, Brucker-Davis F, Turner ML, Sarlis NJ, Skarulis MC. Thyroid 2003; 13: 465–70.

Three women did not show a statistically significant benefit from octreotide 300 µg.

The conflicting results from these small studies regarding the use of octreotide for thyroid dermatopathy mandates that only larger, controlled studies will verify whether it is a useful modality for this condition.

Effect of plasmapheresis and steroid treatment on thyrotropin binding inhibitory immunoglobulins in a patient with exophthalmos and a patient with pretibial myxedema

Kuzuya N, DeGroot LJ. J Endocrinol Invest 1982; 5: 373–8.

Two patients, one with elephantiasis-like lesions, were treated with 16 exchanges over 4 to 5 months with 1 to 2 L of the patient's plasma removed and replaced with 1300 mL of purified protein fraction and 700 mL 0.9% saline. Immunoglobulin G fraction was separated out, thereby reducing total thyrotropin-binding inhibitory immunoglobulin (TBII) activity per unit of serum. The pretibial myxedema was partially and temporarily improved with plasmapheresis, and abnormal antibodies were reduced.

Beneficial effects of plasmapheresis followed by immunosuppressive therapy in pretibial myxedema

Noppen M, Velkeniers B, Steenssens L, Vanhaelst L. *Acta Clin Belg* 1988; 43: 381–3.

A patient with pretibial myxedema unresponsive to topical corticosteroids was cured after 5 days of plasmapheresis followed by 100 mg of azathioprine twice daily for 3 months. Azathioprine was tapered to 50 mg twice daily and continued for a year, at which time no recurrence was noted.

Pretibial myxedema (elephantiasic form): treatment with cytotoxic therapy

Hanke CW, Bergfeld WF, Guirguis MN, Lewis LJ. *Cleve Clin Q* 1983; 50: 183–8.

Fibroblasts from pretibial myxedema sites of a 44-year-old man showed reduced DNA content in vitro with the use of cytotoxic agents. Melphalan, which reduced hyaluronic acid levels to the greatest extent, was given orally (8 mg daily) for 4 days and repeated monthly for 6 months. This regimen provided transient improvement, but the patient's condition then worsened.

Successful combined surgical and octreotide treatment of severe pretibial myxoedema reviewed after 9 years

Felton J, Derrick EK, Price ML. *Br J Dermatol* 2003; 148: 825–6.

A 56-year-old man with pretibial myxedema was treated with surgical shave removal followed by daily subcutaneous octreotide injections for 6 months. His lesions did not recur over a 9-year follow-up period.

Pretibial myxedema

Matsuoka LY, Wortsman J, Dietrich JG, Pearson R. *Arch Dermatol*

1981; 117: 250–1.

Pretibial myxedema recurred in a split-thickness skin graft 3 years after placement.

Treatment-resistant elephantiasic thyroid dermopathy responding to rituximab and plasmapheresis

Heyes C, Nolan R, Leahy M, Gebauer K. *Australas J Dermatol* 2012; 53: e1–4.

A 55-year-old woman underwent plasmapheresis once every 6 days and received rituximab infusions once per week for 1 to 7 weeks on seven occasions for a total of 29 doses of rituximab and 241 episodes of plasmapheresis over 3.5 years. She remained clear 6 months after completion of treatment.

Rituximab has been utilized successfully for an ever-expanding list of autoimmune disorders. Further study is warranted to determine whether rituximab without the concomitant use of plasmapheresis would be of value.

Elephantiasic pretibial myxedema: a novel treatment for an uncommon disorder

Susser WS, Heermans AG, Chapman MS, Baughman RD. *J Am Acad Dermatol* 2002; 46: 723–6.

A 67-year-old woman with elephantiasic pretibial myxedema had a 47% reduction of leg edema after 6 weeks of intensive complete decongestive physiotherapy. This response was sustained for 2 years after treatment.

Complete decongestive physiotherapy consists of manual massage of the lower extremities to promote lymphatic drainage, followed by compressive bandages, exercise, and skin care.

Efficacy of trimodality therapy for pretibial myxoedema: a case series of 20 patients

Chen X, Zhao X, Li X, Shi R, Zheng J. *Acta Derm Venereol* 2016; 96: 714–5.

Severe thyroid dermopathy was treated for 12 weeks. The triple therapy comprised intralesional injections of betamethasone dipropionate 5 mg and betamethasone disodium phosphate 2 mg for a total of 4 to 6 mL, topical 0.1% mometasone furoate cream under occlusive dressing, and UVA1 at a dose of 80 J/cm² per treatment three times a week for 2 weeks, twice a week for 2 weeks, and once a week for 8 weeks. At the end of the trimodality treatment, 8 and 12

patients achieved complete and partial remission, respectively. Dermal thickness was decreased as detected by ultrasound.

Radiation therapy as part of the therapeutic regimen for extensive multilocular myxedema in a patient with exophthalmos, myxedema and osteoarthropathy syndrome: a case report

Elsayad K, Kriz J, Bauch J, Scobioala S, Haverkamp U, Sunderkötter C, et al. *Oncol Lett* 2015; 9: 2404–8.

A 48-year-old male patient was diagnosed with thyroid dermopathy in the setting of proptosis and acropathy. Radiation therapy was commenced to treat the lower left leg and foot at a total dose of 5 Gy. Simultaneously, radiotherapy of the lower right leg and foot was commenced, with the administration of ≤ 20 Gy. Radiotherapy was well tolerated, with the exception of skin edema and slight erythema. Results were maintained with follow-up excision, pentoxifylline, and repeat radiation.

Prurigo nodularis

Junie Li Chun Wong, and Niall Wilson

Nodular prurigo (NP, also known as *prurigo nodularis* or *prurigo nodularis of Hyde*) is a chronic condition characterized by the presence of highly pruritic, hyperkeratotic papules or nodules, ranging from a few to hundreds in numbers. Accompanying features include severe excoriation, crusting, and lichenification and the presence of postinflammatory hyperpigmentation or hypopigmentation. Lesions are often distributed symmetrically over the extensor surfaces of the limbs. However, any other part of the body, particularly the sacral area, abdomen, face, palms, and genitalia, may be affected.

NP may arise at any age but more commonly develops in middle age with a slight female preponderance. It is often regarded as a secondary reaction to chronic pruritus and scratching rather than as a primary cutaneous disease. In over 80% of patients, an underlying cause can be found. This is most commonly atopy, which is present in just under 50% of cases. Cutaneous disorders associated with the development of NP include atopic eczema, venous eczema, allergic contact eczema, dermatitis herpetiformis, Grover disease, lichen planus, and cutaneous lymphoma.

Metabolic diseases have been identified in up to 40% of cases. Diabetes mellitus, thyroid diseases, food (sorbitol, lactose, and fructose) intolerance and malabsorption, iron deficiency, and renal and hepatic failure have all been described. Infections with *Helicobacter pylori*, hepatitis C and human immunodeficiency virus (HIV), underlying malignancies, and neurologic causes such as neuropathy and chronic pain syndrome have also been reported. Concomitant psychosocial disorders can be found; anxiety and depression may be primary associations or secondary to the chronic pruritus of NP.

Management Strategy

Management should be holistic and directed toward treating the symptoms of pruritus and identifying and correcting any underlying cause. A thorough medical history and physical examination, in combination with a range of relevant investigations, are needed to determine any driver (or drivers) for the itching, whether cutaneous, systemic, or psychological.

General measures such as clipping the fingernails and recommending the use of gloves and mittens can help reduce excoriation. Patients should be encouraged to apply emollients regularly, as xerosis can worsen pruritus. Preparations containing menthol, camphor, or phenol can be useful.

Oral antihistamines are effective for symptom control, and the use of sedating antihistamines such as promethazine 25 to 75 mg may be helpful at night. Potent topical or intralesional corticosteroid injections (triamcinolone acetonide 40 mg/mL injected in amounts of 0.1 mL/nodule and repeated every 6 weeks) can be used to treat individual lesions. Topical calcineurin inhibitors or topical vitamin D₃

analogs may be used as adjuncts or substitutes for topical corticosteroids to ameliorate the risk of skin atrophy associated with prolonged use of the latter. The use of occlusive bandaging or dressings such as hydrocolloid pads, preferably in combination with a topical medication, can interrupt the itch–scratch cycle and facilitate the healing of lesions.

Other oral antipruritic agents include antiepileptic drugs, such as pregabalin 25 mg or gabapentin 300 mg three times a day, or tricyclic antidepressants, such as amitriptyline initially started at a low dose of 10 to 25 mg taken at night. Naltrexone, an opioid receptor antagonist, has been reported to have a potent antipruritic effect in patients with NP. These agents may be more useful for cases with underlying neurologic or psychological causes.

In cases with more widespread involvement, phototherapy with narrowband ultraviolet B (UVB), broadband UVB, psoralens and ultraviolet A (PUVA), or long-wavelength ultraviolet A (UVA1) may be helpful. In severe cases that have failed to respond to topical treatment or phototherapy, systemic immunosuppressive agents such as ciclosporin, azathioprine, and methotrexate can be considered. These may be particularly effective for NP associated with atopic eczema. Thalidomide, due to its side effect profile, should be reserved for patients with debilitating disease in whom all other conventional treatment options have failed.

In cases of NP with an identifiable underlying cause, treatment should be directed toward correcting this; for example, prescribing iron supplements in iron-deficiency anemia.

Specific Investigations

- Full blood count
- Blood urea, creatinine, and electrolytes
- Liver function tests
- Hematinics (iron studies, vitamin B₁₂ and folate)
- Calcium
- Thyroid function tests
- Erythrocyte sedimentation rate
- Consider hepatitis B and C and HIV serology
- Consider chest x-ray
- Consider serum immunoglobulin levels and electrophoresis

- Consider total serum IgE
- Consider indirect immunofluorescence
- Consider biopsies for histopathology and direct immunofluorescence to exclude differential diagnoses such as pemphigoid nodularis and squamous cell carcinoma in cases with lone or a small number of lesions

Nodular prurigo: a clinicopathological study of 46 patients

Rowland Payne CM, Wilkinson JD, McKee PH, Jurecka W, Black MM. Br J Dermatol 1985; 113: 431–44.

The clinical presentations; associated disorders; hematologic, renal, hepatic, and microbiologic results; and histologic findings of 46 patients are described in this study.

Prurigo as a symptom of atopic and nonatopic diseases: aetiologic survey in a consecutive cohort of 108 patients

Iking A, Grundmann S, Chatzigeorgakidis E, Phan NQ, Klein D, Stander S. J Eur Acad Dermatol Venereol 2013; 27: 550–7.

The distribution of coexisting diseases affecting NP patients is described in the largest cohort study of NP to date.

Nodular prurigo: metabolic diseases are a common association

Winhoven SM, Gawkrödger DJ. Clin Exp Dermatol 2007; 32: 224–5.

Psychosocial and metabolic disorders—in particular, diabetes mellitus—are commonly associated with NP, as demonstrated in this retrospective analysis of 72 patients.

First-Line Therapies

• Topical corticosteroid	A
• Topical calcineurin inhibitor	A
• Topical corticosteroids with occlusion	C
• Occlusion	E
• Antihistamines	D
• Intralesional corticosteroids	E

Prurigo nodularis

Rowland Payne CME. In: Bernhard JD, ed. Itch – Mechanisms and Management of Pruritus. New York: McGraw-Hill, 1994; 103–19.

Based on a series of 67 patients, the overall patient management of NP is discussed comprehensively.

Evaluation of the antipruritic effects of topical pimecrolimus in nonatopic prurigo nodularis: results of a randomized, hydrocortisone-controlled, doubled-blind phase II trial

Siepmann D, Lotts T, Blome C, Braeutigam M, Phan NQ, Butterfass-Bahloul T, et al. Dermatology 2013; 227: 353–60.

The antipruritic effects of 1% hydrocortisone and 1% pimecrolimus creams are compared in this within-participant, right-left, controlled trial involving 30 patients. A significant reduction in pruritus intensity was achieved on both pimecrolimus- and hydrocortisone-treated sites. No therapeutic difference between pimecrolimus and hydrocortisone was found. Dermatology Life Quality Index scores among subjects improved significantly after treatment.

This is one of very few comparative trials of topical therapies for NP. Although this study looked at the relative efficacy of hydrocortisone, other studies had employed the use of at least potent-strength topical corticosteroids. The highly pruritic nature of NP is such that the use of potent or superpotent topical corticosteroids is often necessary and should be used as first-line treatment.

Treatment of pruritic diseases with topical calcineurin inhibitors

Stander S, Schurmeyer-Horst F, Luger TA, Weisshaar E. *Ther Clin Risk Manag* 2006; 2: 213–8.

Eleven patients were treated with twice-daily application of topical pimecrolimus or tacrolimus. Five patients achieved 70% or greater reduction of itch with healing or major improvement of lesions.

Topical calcineurin inhibitors are known to have antipruritic and immunosuppressive effects in atopic eczema and, as demonstrated in this study, in nonatopic NP. They represent an effective and nonatrophogenic alternative to topical steroids and may potentially be a safer option for long-term use.

An occlusive dressing containing betamethasone valerate 0.1% for the treatment of prurigo nodularis

Saraceno R, Chiricozzi A, Nistico SP, Tiberti S, Chimenti S. *J Dermatolog Treat* 2010; 21: 363–6.

A bilateral-paired comparison study involving 12 patients comparing 0.1% betamethasone valerate tape against a moisturizing itch-relief cream containing feverfew. Occlusion enhanced the efficacy of treatment, preventing scratching, and the side treated with betamethasone valproate 0.1% tape demonstrated a higher clinical response.

Use of occlusive membrane in prurigo nodularis

Meyers LN. *Int J Dermatol* 1989; 28: 275–6.

Four patients with NP responded to weekly application of an occlusive hydrocolloid pad, which also served as a negative reinforcer of scratching.

The use of adhesive occlusive pads, dressings, or bandaging can serve as a deterrent to repetitive scratching of the skin that perpetuates the disease and can disrupt the itch–scratch cycle.

Second-Line Therapies

• Topical vitamin D ₃ analog	A
• UVB phototherapy	D
• Narrowband UVB	C
• PUVA or bath PUVA	B
• UVA1 phototherapy	D
• Monochromatic excimer light	C
• Modified Goeckerman regimen	E

Double-blind, right/left comparison of calcipotriol ointment and betamethasone ointment in the treatment of prurigo nodularis

Wong SS, Goh CL. Arch Dermatol 2000; 136: 807–8.

A randomized, double-blind, right/left comparative study evaluating the efficacy of calcipotriol ointment versus 0.1% betamethasone valerate ointment. Calcipotriol was found to be more effective than betamethasone valerate after 8 weeks of treatment, with a greater reduction in number and size of nodules from baseline.

Topical vitamin D3 (tacalcitol) for steroid-resistant prurigo

Katayama I, Miyazaki Y, Nishioka K. Br J Dermatol 1996; 135: 237–40.

Nine of 11 patients treated with twice-daily application of topical tacalcitol showed a significant clinical response within 4 weeks.

Phototherapy in nodular prurigo

Divekar PM, Palmer RA, Keefe M. Clin Exp Dermatol 2003; 28: 99–100.

The responses of 14 patients treated with a total of 19 courses of phototherapy (8 courses of broadband UVB, 4 courses of bath PUVA, and 7 courses of oral PUVA) are reported. Partial resolution was achieved in 68% of treatment courses. Complete resolution occurred

in three patients, but two relapsed within 1 year.

Narrow-band ultraviolet B phototherapy in patients with recalcitrant nodular prurigo

Tamagawa-Mineoka R, Katoh N, Ueda E, Kishimoto S. *J Dermatol* 2007; 34: 691–5.

Ten patients with recalcitrant NP received once-weekly narrowband UVB therapy. Complete or marked clearance was achieved in all patients after a mean cumulative dose of 23.88 J/cm² over a mean of 24 sessions. At 1-year follow up, only one patient had relapsed.

UV treatment of generalized prurigo nodularis

Hann SK, Cho MY, Park YK. *Int J Dermatol* 1990; 29: 436–7.

The treatment of two patients with UVB, followed by the use of topical PUVA for resistant lesions, is described.

Phototherapy of generalized prurigo nodularis

Bruni E, Caccialanza M, Piccinno R. *Clin Exp Dermatol* 2010; 35: 549–50.

Nineteen patients with generalized NP who had failed a range of previous therapies, including topical corticosteroids, coal tar, oral antihistamines, and ciclosporin, were treated with phototherapy mainly in the UVA range with a spike at 390 nm. A median number of 23 sessions, with a mean total dose of 6.07 J/cm², was required. Out of 15 patients who improved with treatment, 2 patients achieved complete remission, and 8 patients achieved marked improvement.

Long-term results of topical trioxsalen PUVA in lichen planus and nodular prurigo

Karoven J, Hannuksela M. *Acta Derm Venereol* 1985; 120: 53–5.

Bath and ointment trioxsalen PUVA (primary treatment episode of 2–4 weeks, with mean cumulative dose of 7 J/cm²) was initiated in 63 patients with NP. Good results were achieved in 81% of patients. At follow-up over 1 to 6 years, 18% of patients were totally healed, although the majority of patients relapsed and further treatments were required to maintain results.

Efficacy of UVA1 phototherapy in 230 patients with various skin diseases

Rombold S, Lobisch K, Katzer K, Grazziotin TC, Ring J, Eberlein B. Photodermatol Photoimmunol Photomed 2008; 24: 19–23.

UVA1 was given to 17 patients with NP, with a mean cumulative dose of 650 J/cm² given over a mean of 13.9 irradiations. Improvement was observed in 82% of patients, with 41% of patients achieving a marked improvement.

Monochromatic excimer light (308 nm) in the treatment of prurigo nodularis

Saraceno R, Nistico SP, Capriotti E, de Felice C, Rhodes LE, Chimenti S. Photodermatol Photoimmunol Photomed 2008; 24: 43–5.

A study of 11 patients treated with weekly monochromatic excimer light (MEL). Partial or complete clinical and histologic remission was observed in all 9 patients who completed an average of eight treatment sessions.

UVB 308-nm excimer light and bath PUVA: combination therapy is very effective in the treatment of prurigo nodularis

Hammes S, Hermann J, Roos S, Ockenfels HM. J Eur Acad Dermatol Venereol 2011; 25: 799–803.

The efficacy of bath PUVA alone versus combination of PUVA and MEL was compared in this randomized, unblinded study involving 22 patients. Adding MEL sped up the healing process and required 30% less PUVA radiation. There was no significant difference in the proportion of patients achieving complete clearance.

Successful use of a modified Goeckerman regimen in the treatment of generalized prurigo nodularis

Sorenson E, Levin E, Koo J, Berger TG. J Am Acad Dermatol 2015; 72: 40–2.

Four patients were treated with an outpatient modified Goeckerman regimen consisting of 5 days per week broadband UVB therapy followed by application of crude coal tar and topical corticosteroids under occlusion for 4 hours. After a mean 45.5 sessions of modified Goeckerman therapy, patients continued with three sessions of broadband UVB per week with topical steroids applied to recalcitrant nodules. Remission lengths between 2.5 and 8 months were observed.

Third-Line Therapies

• Cryotherapy	E
• Capsaicin	B
• Pulsed dye laser	E
• Fexofenadine and montelukast	C
• Naltrexone	C
• Pregabalin	B
• Gabapentin	E
• Ciclosporin	C
• Azathioprine	E
• Methotrexate	C
• Thalidomide	C
• Lenalidomide	E
• Oral tacrolimus	E
• Intravenous immunoglobulin	E

Cryotherapy improves prurigo nodularis

Waldinger TP, Wong RC, Taylor WB, Voorhees JJ. Arch Dermatol

1984; 120: 1598–600.

A patient with corticosteroid and phototherapy-resistant NP was treated successfully with blistering cryotherapy.

Cryotherapy to the point of blistering may cause scarring and hypopigmentation, as it did in this patient.

Treatment of prurigo nodularis: use of cryosurgery and intralesional steroids plus lidocaine

Stoll DM, Fields JP, King LE Jr. J Dermatol Surg Oncol 1983; 9: 922–4.

Two patients were treated with liquid nitrogen applied with a cotton-tipped applicator for a freeze time of 10 seconds, followed by intralesional injection of triamcinolone acetonide (10 mg/mL) mixed with lidocaine (lignocaine) 0.75%. All lesions resolved after four to eight injections at 4- to 6-week intervals.

Treatment of prurigo nodularis with topical capsaicin

Stander S, Luger T, Metze D. J Am Acad Dermatol 2001; 44: 471–8.

Topical capsaicin (0.025%–0.3%) was administered to 33 patients four to six times daily, over periods ranging from 2 weeks to 10 months. Pruritus resolved in all patients within 12 days but returned in 16 of 33 patients within 2 months of discontinuation of therapy.

Nodular prurigo successfully treated with the pulsed dye laser

Woo PN, Finch TM, Hindson C, Foulds IS. Br J Dermatol 2000; 143: 215–6.

A patient with NP unresponsive to topical and intralesional steroids and PUVA improved after six sessions of treatment with pulsed dye laser (595 nm), spaced 6 weeks apart. He remained symptom free 18 months after discontinuation of treatment.

Combination therapy of fexofenadine and montelukast is effective in prurigo nodularis and pemphigoid nodularis

Shintani T, Ohata C, Koga H, Ohyama B, Hamada T, Nakama T, et al. Dermatol Ther 2014; 27: 135–9.

Nine of 12 patients with NP improved after 4 weeks of treatment with 10 mg montelukast once a day and 240 mg fexofenadine twice a day.

Efficacy and safety of naltrexone, an oral opiate receptor antagonist, in the treatment of pruritus in internal and

dermatologic diseases

Metze D, Reimann S, Beissert S, Luger T. *J Am Acad Dermatol* 1999; 41: 533–9.

Naltrexone 50 mg once daily was initiated in 17 patients with NP. Nine patients achieved greater than 50% improvement in pruritus, which contributed to healing of skin lesions. Two of these patients experienced tachyphylaxis after 1 and 7 months but improved when the dose of naltrexone was doubled to 50 mg twice daily.

Treatment of prurigo nodularis with pregabalin

Mazza M, Guerriero G, Marano G, Janiri L, Bria P, Mazza S. *J Clin Pharm Ther* 2013; 38: 16–8.

Thirty patients were treated with pregabalin 25 mg three times a day for 3 months. In 23 patients, a complete resolution of pruritus with reduction of lesions was seen; only 1 patient failed to improve. Treatment was generally well tolerated, and only 6 patients reported side effects.

Therapeutic hotline: treatment of prurigo nodularis and lichen simplex chronicus with gabapentin

Gencoglan G, Inanir I, Gunduz K. *Dermatol Ther* 2010; 23: 194–8.

Four patients with NP were treated with gabapentin and achieved at least partial remission.

Antipruritic effect of ciclosporin microemulsion in prurigo nodularis: results of a case series

Siepmann D, Luger TA, Stander S. *J Dtsch Dermatol Ges* 2008; 6: 941–6.

Monotherapy with oral ciclosporin (3–5 mg per kg daily) was initiated in 14 patients. Ten patients experienced at least 80% reduction of pruritus and in 3 patients, pruritus reduced by 40% to 70%, with healing of prurigo nodules during treatment. Maximal antipruritic effect was observed after 2 weeks to 12 months. Fifty percent of patients described side effects. One patient developed angioedema, and another patient had to abort treatment after embolism of the popliteal artery.

Nodular prurigo responsive to azathioprine

Lear JT, English JS, Smith AG. *Br J Dermatol* 1996; 134: 1151.

The responses of two patients treated with azathioprine 50 mg

twice daily for 6 and 12 months are described. After 2 to 3 months of treatment, pruritus improved and lesions became less prominent. Disease relapse occurred after 2 months of treatment cessation in one patient and after 3 years in another.

Prurigo nodularis: retrospective study of 13 cases managed with methotrexate

Spring P, Gschwind I, Gilliet M. Clin Exp Dermatol 2014; 39: 468–73.

Thirteen patients who failed to respond to topical steroids, phototherapy, and antipruritic agents were treated with subcutaneous injections of methotrexate 7.5 to 20 mg once weekly for a minimum of 6 months. In 10 cases, there was remission or marked improvement (greater than 75% improvement in both clinical assessment of disease activity and patient's perception of symptoms). A trend to improvement was observed in two other patients.

Thalidomide in 42 patients with prurigo nodularis Hyde

Anderson TP, Fogh K. Dermatology 2011; 223: 107–12.

A retrospective study of 42 patients treated with an average dose of thalidomide 100 mg daily over a mean period of 105 weeks. Clinical improvement was observed in 32 patients. Side effects, such as neuropathy and sedation, were the most common reason for discontinuation of treatment.

Efficacy of thalidomide in the treatment of prurigo nodularis

Taefehnoroos H, Truchetet F, Barbaud A, Schmutz JL, Bursztejn AC. Acta Derm Venereol 2011; 91: 344–5.

A retrospective study of 13 patients treated with thalidomide 50 to 200 mg once daily over 3 to 142 months. In 7 patients, pruritus resolved, and a reduction of nodules occurred after a mean treatment duration of 3 months.

Thalidomide is one of the most reported and studied treatments of NP. However, side effects are common and can be serious and unpredictable. These include fatigue, constipation, sedation, dizziness, and peripheral neuropathy, which may be irreversible. It is linked to severe birth defects and must be avoided in pregnant women. As such, thalidomide should be reserved for exceptional circumstances, in debilitating disease, and when other treatment options have been exhausted.

Treatment of refractory prurigo nodularis with lenalidomide

Kanavy H, Bahner K, Korman NJ. Arch Dermatol 2012; 148: 794–6.

A patient with refractory NP who had responded only to thalidomide developed peripheral neuropathy after 18 months of therapy. Lenalidomide was chosen as an alternative due to its similar mechanism of action but reduced risk of peripheral neuropathy. Near-complete resolution of pruritus and visible healing of nodules was achieved after 1 month of treatment with lenalidomide 5 mg/day, and the patient remained in remission during 2 years of treatment.

Oral tacrolimus treatment of pruritus in prurigo nodularis

Halvorsen JA, Aasebo W. Acta Derm Venereol 2015; 95: 866–7.

A patient with NP achieved good response to ciclosporin but experienced hypertrichosis as a side effect. She started periodic treatment with oral tacrolimus 10 to 20 mg daily, alternating with ciclosporin. Monotherapy with tacrolimus led to a reduction of itch but without the side effect of hypertrichosis.

Atopic prurigo nodularis responds to intravenous immunoglobulins

Feldmeyer L, Werner S, Kamarashev J, French LE, Hofbauer GF. Br J Dermatol 2012; 166: 461–2.

A patient with refractory NP achieved dramatic improvement with intravenous immunoglobulins (IVIG, 2 g/kg monthly, given intravenously over 3 days) in combination with methotrexate. After three therapy cycles with IVIG, she experienced sustained improvement on methotrexate and topical steroids.

Prurigo pigmentosa

Yukiko Tsuji-Abe, and Hiroshi Shimizu

Prurigo pigmentosa is a pruritic eruption that begins with urticarial papules or papulovesicles on the neck, chest, and back, followed by reticular pigmentation. It most commonly affects women in their twenties and thirties. Most of the patients reported have been Japanese.

Management Strategy

Prurigo pigmentosa has a distinctive clinical course. Lesions initially start as pruritic, urticarial papules or papulovesicles. The lesions resolve spontaneously within a week, but repetition of the episode

results in reticular pigmentation. The pathogenesis of prurigo pigmentosa remains unknown. Friction from clothing, especially in wet conditions such as sweating or swimming, can trigger the disease. In some cases, ketosis caused by diabetes mellitus, sudden weight loss from a low-carbohydrate diet, or anorexia nervosa precedes prurigo pigmentosa. Treatment of these conditions can lead to clinical resolution. Several case reports described individuals who developed this condition in association with other disorders, including contact allergic reactions to certain chemical agents, infection with *Helicobacter pylori* or spirochetes, an atopic diathesis, and pregnancy.

Minocycline (100–200 mg daily) and *dapsone* (25–100 mg daily) are usually very effective for prurigo pigmentosa. The effects are mostly observed within 3 to 7 days after treatment and lead to reductions in itching and papular lesions. Minocycline is regarded as the first-line therapy because it produces fewer adverse reactions, and the remission is reportedly longer than for dapsone. Topical or systemic corticosteroids and antihistamines are usually ineffective.

Specific Investigation

- Urinalysis for ketones

Unilateral prurigo pigmentosa: a report of two cases

Teraki Y, Hitomi K. J Dermatol 2016; 43: 846–7.

Prurigo pigmentosa: a clinicopathologic study of 16 cases

Oh YJ, Lee MH. J Eur Acad Dermal Venereol 2012; 26: 1149–53.

Prurigo pigmentosa on a patient with soft-drink ketosis

Mitsuhashi Y, Suzuki N, Kawaguchi M, Kondo S. J Dermatol 2005; 32: 767–8.

Prurigo pigmentosa (Nagashima) associated with anorexia nervosa

Nakada T, Sueki H, Iijima M. Clin Exp Dermatol 1998; 23: 25–7.

In all these reports, prurigo pigmentosa was associated with ketosis. Disease activity is sometimes correlated with urinary ketone concentration. In some cases, lesions resolved after treatment of the associated condition.

First-Line Therapies

• Minocycline	C
• Treatment of ketosis or any other potentially causative factors	D

Prurigo pigmentosa: clinicopathological study and analysis of 50 cases in Korea

Kim JK, Chung WK, Chang SE, Ko JY, Lee JH, Won CH, et al. J Dermatol 2012; 39: 891–7.

Among 50 patients, 28 patients were treated with minocycline (100–200 mg daily), 7 with dapsone (100 mg daily), and 4 with both minocycline and dapsone; all patients responded well to these therapies.

Bullous prurigo pigmentosa in a pregnant woman with hyperemesis gravidarum

Hanami Y, Yamamoto T. J Dermatol 2015; 42: 436–7.

A pregnant woman with severe hyperemesis gravidarum lost 7 kg in body weight. The urinary ketone concentration was positive. Her general condition improved with fluid therapy and bed rest, and the skin lesions disappeared after 1 month.

Prurigo pigmentosa associated with diabetic ketoacidosis

Ohnishi T, Kisa H, Ogata E, Watanabe S. Acuta Derm Venereol 2000; 80: 447–8.

Eighteen cases of prurigo pigmentosa were associated with diabetic ketoacidosis. Treatment of ketoacidosis improved eruptions in eight cases, and treatment with topical corticosteroid improved the rash in one case; progress was unknown in one case.

Minocycline (100–200 mg daily) is usually very effective. The effects—reductions in pruritic and papular lesions—are mostly observed within a few days after treatment. The therapeutic effects of minocycline and the antibiotics described next are likely attributable to the fact that leukocyte activation and inflammation are key pathologic features in prurigo pigmentosa.

Second-Line Therapies

• Dapsone	C
• Doxycycline	E
• Roxithromycin	E
• Clarithromycin	E

Prurigo pigmentosa in Korea: clinicopathological study

Shin JW, Lee SY, Lee JS, Whang KU, Park YL, Lee HK. Int J Dermal 2012; 51: 152–7.

Dapsone and minocycline were used alone or in combination to treat 37 of 49 patients. Lesions and pruritus rapidly resolved in all patients.

Prurigo pigmentosa: a clinical and histopathologic study of 11 cases

Lin SH, Ho JC, Cheng YW, Huang PH, Wang CY. Chang Gung Med J 2010; 33: 157–63.

Among 11 patients with prurigo pigmentosa, 10 patients were treated with doxycycline (200 mg daily) and exhibited a good response.

Prurigo pigmentosa: not an uncommon disease in the Turkish population

Baykal C, Buyukbabani N, Akinturk S, Saglik E. Int J Dermatol 2006; 45: 1164–8.

Three of six patients with prurigo pigmentosa responded well to

doxycycline 100 mg daily; another three responded well to tetracycline 500 mg daily.

The successful treatment of prurigo pigmentosa with macrolide antibiotics

Yazawa N, Ihn H, Yamane K, Etoh T, Tamaki K. *Dermatology* 2001; 202: 67–9.

Two patients with prurigo pigmentosa responded well to roxithromycin 300 mg daily; another two responded well to clarithromycin 400 mg daily. In all patients, the effect was quick, and pruritus and papules disappeared within 1 week.

Prurigo pigmentosa

Gürses L, Gürbüz O, Demirçay Z, Kotiloglu E. *Int J Dermatol* 1999; 38: 924–5.

One of two patients responded well to doxycycline 200 mg daily; prurigo pigmentosa resolved spontaneously in the other patient.

Doxycycline—a member of the tetracycline antibiotics group—and macrolide antibiotics such as roxithromycin and clarithromycin are reported to be effective for prurigo pigmentosa. These drugs are recommended for patients who respond poorly to first-line treatment and those for whom dapsone and minocycline are contraindicated.

Third-Line Therapies

• Isotretinoin	E
• Narrowband Ultraviolet B (UVB) therapy	E

Vesiculous prurigo pigmentosa in a 13-year-old girl: good response to isotretinoin

Requena Caballero C, Nagore E, Sanmartín O, Botella-Estrada R, Serra C, Guillén C. *Int J Eur Acad Dermatol Venereol* 2005; 19: 474–6.

The initial diagnosis was a vesiculobullous form of Darier disease, and the patient was started on isotretinoin 40 mg/day, which resulted in a good response in 10 days. The lesion relapsed 5 months later, and treatment with minocycline 100 mg/day resulted in resolution within

7 days.

Prurigo pigmentosa successfully treated with low-dose isotretinoin

Akoglu G, Boztepe G, Karaduman A. *Dermatology* 2006; 213: 331–3.

An 18-year-old woman was successfully treated with isotretinoin 20 mg daily (0.3 mg/kg/day). Pruritus and erythematous macules resolved within 1 month after the start of therapy.

Successful treatment with narrowband UVB phototherapy in prurigo pigmentosa associated with pregnancy

Jang MS, Baek JW, Kang DY, Kang JS, Kim ST, Suh KS. *Eur J Dermatol* 2011; 21: 634–5.

A woman in the thirteenth week of pregnancy was treated with narrowband UVB for prurigo pigmentosa. Pruritus decreased significantly after the first irradiation, and erythema resolved after the fifth session.

Most patients with prurigo pigmentosa respond well to first- or second-line therapies or achieve spontaneous remission, but these treatment alternatives might be useful in unusual cases.

Pruritus

Amit Garg, and Jeffrey D. Bernhard

Pruritus is a cutaneous sensation (usually unpleasant) that evokes an urge to scratch, rub, pick, and, in extreme cases, mutilate the skin in an attempt to obtain relief. We use the terms *itch* and *pruritus* interchangeably. Itch occurs as a characteristic feature of many skin diseases, such as atopic dermatitis, bullous pemphigoid, lichen planus, and scabies. It can also occur as an unusual symptom of certain systemic disorders, such as hyperthyroidism, cholestasis, and uremia. Pruritus in the absence of a detectable rash, whether localized or generalized, poses both a diagnostic and therapeutic challenge to even the most seasoned dermatologist. To make matters even worse, secondary changes caused by rubbing and scratching may camouflage specific physical findings. New discoveries in the neurophysiology of itch have led to specific therapies that target particular pathways and receptors in the nervous system.

Management Strategy

Management of pruritus is directed toward its cause, which may not always be apparent. Many different dermatoses itch; it is beyond the scope of this chapter to discuss them all. Xerosis and scabies deserve special mention because both can have subtle findings with intense itching out of proportion to the rash. In xerosis, an adequate skin care regimen and emollients are indispensable. One of the more common and embarrassing errors is to miss the diagnosis of scabies; consideration of this diagnosis may avoid undue suffering and delays in treatment. Pre-bullous pemphigoid, dermatitis herpetiformis, adult-onset atopic dermatitis, cutaneous lymphoma, and drug reactions are among the other most difficult to diagnose diseases of the skin.

Failure to diagnose a primary skin disease does not rule out the possibility that one is present; time, repeated observation, and laboratory tests such as a skin biopsy may be required. When no rash is present, or when a rash is present but cannot be diagnosed, further evaluation is indicated. The evaluation should include a thorough medical history and physical examination, complete with a precise medication review and review of systems. The physical examination should include palpation for organomegaly and lymphadenopathy. The examiner should not be misled by nonspecific secondary changes caused by rubbing, scratching, or secondary infection. A “peculiar” eczematous dermatitis resistant to treatment may be a secondary phenomenon, not necessarily the primary diagnosis. Laboratory investigations are often essential in the clinical assessment of chronic pruritus, whether a rash is present or not. The presence or absence of constitutional signs or symptoms should be determined at the initial and follow-up visits.

The most serious error is to miss the diagnosis of an underlying systemic disease associated with pruritus. Some of the systemic disorders that may cause pruritus include hematologic and solid malignancies, lymphoproliferative disorders, HIV, thyroid disease, iron deficiency, renal disease, hepatobiliary disease, connective tissue disease, neurologic disease, and drug hypersensitivity. Interval reevaluation for associated systemic disease should be undertaken because pruritus may precede the diagnosis of a systemic disease by many months (as in primary biliary cirrhosis and Hodgkin disease). A review of systems—with particular emphasis on the presence or

absence of constitutional signs or symptoms—may be quite helpful.

For symptomatic relief, general skin hygiene measures (e.g., *moisturization*) and *elimination of exacerbating factors* (e.g., excessively dry air) are worthwhile but rarely sufficient. Tepid water baths using fragrance-free *moisturizing soaps*, *emollients*, *unscented bath oils* applied liberally after bathing, a cool moisture-rich environment, and loose-fitting clothing are helpful. In the management of pruritus that does not respond to simple measures, treatment should be individualized based on etiology, severity, and regard for safety.

Specific Investigations

Screening

- Complete medical history
- Careful medication history
- Thorough review of systems
- Complete physical examination
- Complete blood count with differential
- Blood urea nitrogen, creatinine
- Fasting glucose
- Hepatic function testing
- Thyroid function testing
- Chest radiograph (posteroanterior and lateral)
- Age-appropriate cancer screening

Additional testing to consider

- Scraping for scabies
- Hepatitis B and C profiles
- HIV testing
- Erythrocyte sedimentation rate
- Serum iron and ferritin
- Serum protein electrophoresis, urine protein electrophoresis
- Stool for ova and parasites
- Antimitochondrial antibody test
- Skin biopsy

Itch and pruritus: what are they and how should itches be classified?

Bernhard JD. *Dermatol Ther* 2005; 18: 288–91.

Clinical classification of itch: a position paper of the International Forum for the Study of Itch

Ständer S, Weisshaar E, Mettang T, Szepietowski JC, Carstens E, Ikoma A, et al. *Acta Derm Venereol* 2007; 87: 291–4.

These two papers explain the terms used to signify different categories of pruritic disorders.

Neurophysiological and neurochemical basis of modern pruritus treatment

Ständer S, Weisshaar E, Luger TA. *Exp Dermatol* 2008; 17: 161–9.

This review highlights modern neurophysiologic and neurochemical therapeutic strategies on the basis of neuronal mechanisms underlying chronic pruritus.

Chronic pruritus

Yosipovitch G, Bernhard JD. *N Engl J Med* 2013; 368: 1625–34.

This review describes the evaluation and symptomatic treatment of patients without a clear diagnosis.

Ultraviolet phototherapy for pruritus

Rivard J, Lim HW. *Dermatolog Ther* 2005; 18: 344–54.

Ultraviolet therapy is used to treat a variety of pruritic conditions. In this review, mechanisms of action for phototherapy are discussed. Treatment limitations, side effects, and common dosing protocols are reviewed.

Pruritus in chronic liver disease: mechanisms and treatment

Bergasa NV. *Curr Gastroenterol Rep* 2004; 6: 10–6.

This is an excellent and succinct review of cholestatic pruritus. It presents what is known regarding the pathophysiology of itch and cholestasis, and it discusses targeted treatment strategies in cholestatic disorders.

Neuropathic itch

Neuropathic itch arises as a consequence of pathology at one or more points along the afferent (sensory) pathway of the peripheral or

central nervous system. Brachioradial pruritus (BRP) and notalgia paresthetica (NP) are the two best examples of the isolated sensory peripheral neuropathies seen by dermatologists. It is believed that dorsal spinal nerve radiculopathy, usually secondary to degenerative disease of cervical and thoracic vertebral bodies, leads to persistent itching, paresthesia, hypesthesia, or burning/stinging pain. The involved areas may also be hyperpigmented and excoriated. These forms of localized pruritus may go undiagnosed for quite some time. By the time a patient fails to respond to multiple treatments and a dermatology consultation is obtained, the itch has often been going on for months and may have become generalized, often with secondary changes that may be mistaken for a primary dermatosis. Several investigators have observed patients in whom BRP appears to have triggered generalization to areas beyond those normally involved in classic BRP.

Although evidence for the use of *gabapentin* in the treatment of BRP and NP is mostly anecdotal to date, it is being used increasingly with success for more widespread or otherwise recalcitrant neuropathic dysesthesias, including itch and pain. Doses as high as 3600 mg daily in three or four divided doses, as tolerated, may be necessary.

Pregabalin, an analog of gabapentin, has also been effective in the treatment of neuropathic pain syndromes (such as postherpetic neuralgia and diabetic neuropathy); there is evidence that it is effective in treating neuropathic itch as well (e.g., BRP and postherpetic pruritus) in doses ranging from 150 to 450 mg in two to three divided doses. Repeated application of *capsaicin cream*, which depletes axonal stores of substance P, may be an effective approach to the treatment of localized areas of neuropathic pain or itch. Although there is evidence to support its use for neuropathic itch, in practice the application of capsaicin is limited by its low tolerability, its restriction to smaller application areas, and its unknown long-term safety risks.

First-Line Therapy

• Gabapentin or pregabalin

D

Gabapentin treatment for notalgia paresthetica, a common isolated peripheral sensory neuropathy

Loosemore MP, Bordeaux JS, Bernhard JD. *J Eur Acad Dermatol Venereol* 2007; 21: 1440–1.

An 82-year-old man with NP and BRP was treated with gabapentin 600 mg at night with resolution of symptoms. Symptoms recurred when gabapentin was stopped and then resolved with reinitiation of the medication.

Brachioradial pruritus: response to treatment with gabapentin

Winhoven SM, Coulson IH, Bottomley WW. *Br J Dermatol* 2004; 150: 786–7.

In this report, two patients with BRP resistant to other therapies responded to gabapentin 300 mg three times daily.

Brachioradial pruritus: report of a new case responding to gabapentin

Kanitakis J. *Eur J Dermatol* 2006; 16: 311–2.

A 54-year-old man with BRP noted significant (90%) improvement in pruritus with gabapentin 600 mg three times daily and the use of an antipruritic cream containing 8% calamine and essential fatty acids. He initially had diarrhea and sleepiness at this dose. Pruritus returned with discontinuation of gabapentin and again resolved with its reinitiation.

Gabapentin treatment for brachioradial pruritus

Bueller HA, Bernhard JD, Dubroff LM. *J Eur Acad Dermatol Venereol* 1999; 13: 227–8.

First report on the use of this class of drugs for the treatment of neuropathic itches such as BRP. BRP is probably more common than previously realized, and it can be unbearable.

Pregabalin in the treatment of chronic pruritus

Ehrchen J, Ständer S. *J Am Acad Dermatol* 2008; 58: S36–7.

Second-Line Therapy

• Capsaicin

A

Successful treatment of notalgia paresthetica with topical capsaicin: vehicle-controlled, double-blind, crossover study

Wallengren J, Klinker M. J Am Acad Dermatol 1995; 32: 287–9.

In this 10-week study, 20 patients with notalgia paresthetica were treated with capsaicin cream or placebo five times daily for 1 week and then three times daily for 3 weeks. Treatment was stopped for 2 weeks before all patients using capsaicin cream resumed the same schedule as before. Seventy percent of patients treated with capsaicin cream had improved symptoms compared with only 30% on placebo. Pruritus did not intensify during the washout period in patients who received capsaicin cream in the first 4 weeks.

Successful treatment of refractory neuropathic pruritus with capsaicin 8% patch: a bicentric retrospective study with long-term follow-up

Misery L, Erfan N, Castela E, Brenaut E, Lantéri-Minet M, Lacour JP, et al. Acta Derm Venereol 2015; 95: 864–5.

A retrospective case series in which seven patients with BRP and NP responded to treatment with a capsaicin 8% dermal patch

Solar (brachioradial) pruritus – response to capsaicin cream

Knight TE, Hayashi T. Int J Dermatol 1994; 33: 206–9.

In this open-label trial of capsaicin cream, 10 of 13 patients completing the study found significant relief (itching much improved or gone) from itch on the treated arm after 3 weeks compared with the untreated control arm.

Cholestatic itch

Cholestasis, a reduction of bile flow, results from a variety of hepatic, as well as extrahepatic, diseases. Although the pathophysiologic link between cholestasis and pruritus is not fully understood, an

increasing body of evidence supports the proposition that it occurs as a consequence of increased levels of endogenous opioids. Pruritus of cholestasis is typically widespread, characteristically involves the palms and soles, and may be accompanied by jaundice. Therapeutic interventions have focused on the removal of presumed pruritogens from the circulation (through the use of *ursodeoxycholic acid*, *cholestyramine*), induction of hepatic enzymes (*rifampin*), antagonism of endogenous opioid receptors (*naltrexone*, *naloxone*, *nalmefene*), modulation of serotonin neurotransmission (*sertraline*), activation of cannabinoid receptors (*dronabinol*), and clearing water-soluble and protein-bound pruritogens through albumin-based dialysis (Molecular Adsorbent Recycling System, Prometheus). *Ultraviolet B (UVB) phototherapy* and parenteral *lidocaine* are further therapeutic considerations.

First-Line Therapies

• Rifampin	A
• Naltrexone, nalmefene, naloxone	A

Rifampin is safe for treatment of pruritus due to chronic cholestasis: a meta-analysis of prospective randomized-controlled trials

Khurana S, Singh P. *Liver Int* 2006; 26: 943–8.

This meta-analysis includes five prospective randomized controlled trials with 61 patients who had pruritus associated with chronic liver disease. Complete or partial resolution of symptoms occurred in 77% of patients taking rifampin 300 to 600 mg daily.

The efficacy and safety of bile acid binding agents, opioid antagonists, or rifampin in the treatment of cholestasis-associated pruritus

Tandon P, Rowe BH, Vandermeer B, Bain VG. *Am J Gastroenterol* 2007; 102: 1528–36.

In this review of 12 randomized controlled trials, both rifampin and

opioid antagonists significantly reduced cholestasis-associated pruritus. There was insufficient data to assess the efficacy of cholestyramine.

Efficacy and safety of oral naltrexone treatment for pruritus of cholestasis, a crossover, double blind, placebo-controlled study

Terg R, Coronel E, Sordá J, Muñoz AE, Findor J. J Hepatol 2002; 37: 717–22.

In this double-blind, randomized, placebo-controlled crossover trial of 20 patients with cholestasis-associated pruritus, 9 of 20 patients taking naltrexone 50 mg daily experienced a greater than 50% reduction in symptoms relative to baseline, including 5 whose pruritus disappeared completely. Adverse effects included a short-lived opioid withdrawal-like phenomenon.

Oral nalmefene therapy reduces scratching activity due to the pruritus of cholestasis: a controlled study

Bergasa NV, Alling DW, Talbot TL, Wells MC, Jones EA. J Am Acad Dermatol 1999; 41: 431–4.

In a randomized, double-blind, placebo-controlled study with pruritus associated with chronic liver disease, nalmefene therapy was associated with a 75% reduction in the mean hourly scratching activity and a decrease in the mean visual analog scale (VAS) score of the perception of pruritus in all eight patients.

Effects of naloxone infusions in patients with the pruritus of cholestasis. A double-blind, randomized, controlled trial

Bergasa NV, Alling DW, Talbot TL, Swain MG, Yurdaydin C, Turner ML, et al. Ann Intern Med 1995; 123: 161–7.

In this double-blind, placebo-controlled, crossover trial in 29 patients with liver disease, naloxone infusions resulted in significantly improved VAS scores and hourly scratching activity compared with placebo.

The itch of liver disease

Bergasa NV. Semin Cutan Med Surg 2011; 30: 93–8.

Update on the treatment of the pruritus of cholestasis

Bergasa NV. Clin Liver Dis 2008; 12: 219–34.

Two relevant discussions on pruritus of cholestasis, its mechanism,

and endogenous mediators, as well as the potential role of a behavioral component to disease manifestation.

Second-Line Therapies

• Cholestyramine	A
• Ursodeoxycholic acid	A
• Sertraline	A

Double-blind placebo-controlled clinical trial of microporous cholestyramine in the treatment of intra- and extra-hepatic cholestasis: relationship between itching and serum bile acids

Di Padova C, Tritapepe R, Rovagnati P, Rossetti S. *Methods Find Exp Clin Pharmacol* 1984; 6: 773–6.

In this double-blind, placebo-controlled trial in 10 patients, microporous cholestyramine 3 g three times daily over a 4-week period significantly reduced itch intensity and serum bile acids over placebo.

Randomised controlled trials of ursodeoxycholic-acid therapy for primary biliary cirrhosis: a meta-analysis

Goulis J, Leandro G, Burroughs AK. *Lancet* 1999; 354: 1053–60.

In this meta-analysis, ursodeoxycholic acid was effective in treating pruritus associated with primary biliary cirrhosis in 2 of 11 randomized controlled trials.

The potent bile acid sequestrant colesevelam is not effective in cholestatic pruritus: results of a double-blind, randomized, placebo-controlled trial

Kuiper EM, van Erpecum KJ, Beuers U, Hansen BE, Thio HB, de Man RA, et al. *Hepatology* 2010; 52: 1334–40.

In this randomized, double-blind, multicenter trial, 35 patients with cholestatic pruritus received 1875 mg of colesevelam, an anion-exchange resin with a sevenfold higher bile acid-binding capacity than cholestyramine, or an identical placebo twice daily for 3 weeks. Despite significantly lower mean serum bile acid levels in the colesevelam-treated group, there was no significant difference between groups with respect to the following: percent of patients with $\geq 40\%$ reduction in pruritus VAS scores, quality-of-life scores, and severity of cutaneous scratch lesions.

Sertraline as a first-line treatment for cholestatic pruritus

Mayo MJ, Handem I, Saldana S, Jacobe H, Getachew Y, Rush AJ. *Hepatology* 2007; 45: 666–74.

In this randomized, double-blind, placebo-controlled trial, 21 patients with pruritus associated with chronic liver disease experienced significant improvements in perceived itch and in physical evidence of scratching while taking sertraline 75 to 100 mg daily.

Long-term efficacy of sertraline as a treatment for cholestatic pruritus in patients with primary biliary cirrhosis

Browning J, Combes B, Mayo MJ. *Am J Gastroenterol* 2003; 98: 2736–41.

A retrospective report of 40 patients enrolled in a prospective study to examine the efficacy of ursodeoxycholic acid in patients with primary biliary cirrhosis. These patients kept itch diaries during the study. Itch in six of seven patients started on sertraline for depression improved significantly, and these patients were able to discontinue other medications for itch.

Third-Line Therapies

• Albumin-based dialysis	E
• Ultraviolet B phototherapy	E
• Parenteral lidocaine	A
• Dronabinol	E

Treatment of severe refractory pruritus with fractionated plasma separation and adsorption (Prometheus)

Rifai K, Hafer C, Rosenau J, Athmann C, Haller H, Peter Manns M, et al. Scand J Gastroenterol 2006; 41: 1212–7.

Seven patients with recalcitrant pruritus associated with liver disease were treated with Prometheus for three to five sessions. Six patients with bile acid elevations reported significant improvement in pruritus, which was also associated with a parallel decrease in serum bile acids. The patient with no initial bile acid elevation did not report an improvement in pruritus. In four of the six patients, improvement lasted at least 4 weeks.

Therapy of intractable pruritus with MARS

Acevedo Ribó M, Moreno Planas JM, Sanz Moreno C, Rubio González EE, Rubio González E, Boullosa Graña E, et al. Transplant Proc 2005; 37: 1480–1.

All three patients with intractable pruritus associated with primary biliary cirrhosis who underwent two to three sessions of the molecular adsorbent recirculating system had marked improvement of pruritus and decreased bilirubin levels. Improvement lasted only a few days in all cases.

Extracorporeal albumin dialysis: a procedure for prolonged relief of intractable pruritus in patients with primary biliary cirrhosis

Pares A, Cisneros L, Salmeron JM, Caballería L, Mas A, Torras A, et al. Am J Gastroenterol 2004; 99: 1105–10.

Four patients with recalcitrant pruritus associated with primary

biliary cirrhosis were treated with two extracorporeal albumin dialysis sessions 1 day apart. Two patients reported resolution of itch, whereas the two other patients reported a marked decrease in pruritus. Scratching decreased in a parallel fashion to reduced pruritus. Pruritus eventually recurred over months in all four patients.

Treatment of intractable pruritus in drug induced cholestasis with albumin dialysis: a report of two cases

Bellmann R, Feistritz C, Zoller H, Graziadei IW, Schwaighofer H, Propst A, et al. ASAIO J 2004; 50: 387–91.

Two patients with drug-induced cholestasis and severe pruritus who underwent three sessions of the molecular adsorbent recirculating system experienced sustained relief of pruritus as well as a decline in plasma bilirubin and serum 3 α -hydroxy bile acid levels.

Phototherapy for primary biliary cirrhosis

Perlstein SM. Arch Dermatol 1981; 117: 608.

In this case report, two patients with pruritus treated with weekly UVB phototherapy improved.

Efficacy of lidocaine in the treatment of pruritus in patients with chronic cholestatic liver diseases

Villamil AG, Bandi JC, Galdame OA, Gerona S, Gadano AC. Am J Med 2005; 118: 1160–3.

In this double-blind trial, 18 patients were randomized (2:1) to receive parenteral lidocaine 100 mg or placebo. Patients receiving lidocaine reported significantly reduced severity of pruritus and fatigue compared with placebo.

Preliminary observation with dronabinol in patients with intractable pruritus secondary to cholestatic liver disease

Neff GW, O'Brien CB, Reddy KR, Bergasa NV, Regev A, Molina E, et al. Am J Gastroenterol 2002; 97: 2117–9.

In this report, three patients with intractable cholestatic-related pruritus were started on 5 mg of dronabinol (Δ^9 -tetrahydrocannabinol) at bedtime with a decrease in pruritus, marked improvement in sleep, and eventual return to work. Resolution of depression occurred in two of three.

Itch associated with cholestasis of pregnancy

First-Line Therapy

• Ursodeoxycholic acid	A
------------------------	---

Ursodeoxycholic acid and S-adenosylmethionine in the treatment of intrahepatic cholestasis of pregnancy: a multi-centered randomized controlled trial

Zhang L, Liu XH, Qi HB, Li Z, Fu XD, Chen L, et al. Eur Rev Med Pharmacol Sci 2015; 19: 3770–6.

In this randomized controlled trial, ursodeoxycholic acid monotherapy, S-adenosylmethionine monotherapy, and both as combined therapy showed similar efficacies for intrahepatic cholestasis of pregnancy.

Intrahepatic cholestasis of pregnancy: amelioration of pruritus by UDCA is associated with decreased progesterone disulphates in urine

Glantz A, Reilly SJ, Benthin L, Lammert F, Mattsson LA, Marschall HU. Hepatology 2008; 47: 544–51.

In this randomized controlled trial, women with intrahepatic cholestasis of pregnancy treated with ursodeoxycholic acid (UDCA) experienced amelioration of pruritus, which was associated with increased hepatobiliary excretion of progesterone disulfates.

Intrahepatic cholestasis of pregnancy: a randomized controlled trial comparing dexamethasone and ursodeoxycholic acid

Glantz A, Marschall HU, Lammert F, Mattsson LA. Hepatology 2005; 42: 1399–405.

In this randomized, double-blind, placebo-controlled trial consisting of 130 women with intrahepatic cholestasis of pregnancy, 3 weeks of UDCA 1 g daily resulted in significant relief from pruritus

and marked reduction of serum bile acids.

Second-Line Therapies

• <i>S</i> -adenosyl-L-methionine	B
• Cholestyramine	B

Randomized prospective comparative study of ursodeoxycholic acid and *S*-adenosyl-L-methionine in the treatment of intrahepatic cholestasis of pregnancy

Binder T, Salaj P, Zima T, Vítek L. J Perinat Med 2006; 34: 383–91.

In this study, 78 women with intrahepatic cholestasis of pregnancy treated with UDCA, *S*-adenosyl-L-methionine, or a combination of the two experienced a significant improvement in pruritus. Only UDCA monotherapy and combination therapy led to improvement in serum concentrations of bile acids and transaminases, with the combination therapy leading to faster results.

A randomised controlled trial of ursodeoxycholic acid and *S*-adenosyl-L-methionine in the treatment of gestational cholestasis

Roncaglia N, Locatelli A, Arreghini A, Assi F, Cameroni I, Pezzullo JC, et al. Br J Obstet Gynaecol 2004; 111: 17–21.

In this study, 46 women with intrahepatic cholestasis of pregnancy and pruritus were randomly assigned to receive oral *S*-adenosyl-L-methionine 500 mg twice daily or oral UDCA 300 mg twice daily. Both therapies significantly and equally improved pruritus. Women receiving UDCA had significantly greater improvements in serum bile acids, aspartate aminotransferase, alanine aminotransferase, and bilirubin.

Efficacy and safety of ursodeoxycholic acid versus cholestyramine in intrahepatic cholestasis of pregnancy

Kondrackiene J, Beuers U, Kupcinskas L. Gastroenterology 2005; 129:

894–901.

In this study, 84 women with intrahepatic cholestasis of pregnancy and pruritus were randomized to receive either UDCA 8 to 10 mg/kg body weight daily or cholestyramine 8 g daily for 14 days. The group receiving UDCA had greater improvement in pruritus, deliveries that were closer to term, greater reductions in serum alanine and aspartate aminotransferase activities, greater decrease in endogenous serum bile acid levels, and fewer adverse effects compared with the group receiving cholestyramine.

Renal itch

Patients with renal itch tend to have dry skin, have increased numbers of dermal mast cells, and may have a variety of unidentified circulating pruritogens, possibly including opioid peptides. Pruritus associated with chronic renal failure is usually an unremitting generalized itch, which is more common among hemodialysis patients. Some dialysis patients experience itch localized to the shunt arm. Presence or intensity of pruritus does not correlate with blood urea or creatinine levels. The condition is difficult to manage, and the only reliably effective treatment remains kidney transplant.

Fortunately, the incidence of uremic pruritus is decreasing as dialysis membranes with improved biocompatibility are being used.

Optimizing general skin care measures with emollients to reduce xerosis should be a fundamental part of the treatment plan.

Antihistamines are generally not helpful for uremic pruritus.

However, the tricyclic antihistamine *doxepin*, whose use in renal itch is not described in the literature, may be helpful because of its sedating and antidepressant properties. Although *UVB phototherapy* is the mainstay of treatment, *gabapentin* and *naltrexone* have also shown efficacy in trials. A number of other less conventional therapeutic interventions have reported success.

First-Line Therapies

• Emollients with high water content	A
• Narrowband UVB phototherapy	B
• Broadband UVB phototherapy	B
• Gabapentin	A
• Pregabalin	B
• Naltrexone	A
• Nalfurafine hydrochloride	B

Effect of skin care with an emollient containing a high water content on mild uremic pruritus

Okada K, Matsumoto K. Ther Apher Dial 2004; 8: 419–22.

In this placebo-controlled trial involving 20 hemodialysis patients with mild pruritus, twice-weekly application of an aqueous gel containing 80 g of water for 2 weeks significantly improved reported pruritus scores and xerosis compared with the control group.

Narrowband ultraviolet B phototherapy for patients with refractory uraemic pruritus: a randomized controlled trial

Ko MJ, Yang JY, Wu HY, Hu FC, Chen SI, Tsai PJ, et al. Br J Dermatol 2011; 165: 633–9.

In this single-blind, randomized, controlled trial patients with refractory uremic pruritus were randomized to receive NB-UVB phototherapy or time-matched long-wave UVA radiation as a control. NB-UVB was given three times per week for 6 weeks. The dose of NB-UVB was started at 210 mJ/cm² and was increased by 10% for each treatment. Both NB-UVB and control groups had significant and comparable improvement in the pruritus-intensity VAS scores during phototherapy and follow-up. Compared with the control group, the NB-UVB group showed a significant improvement in the affected body surface area ($p = 0.006$) but not in sleep quality. The authors concluded that NB-UVB phototherapy does not show a significant

effect in reducing pruritus intensity compared with a control group for refractory uremic pruritus.

Treatment of uremic pruritus with narrowband ultraviolet B phototherapy: an open pilot study

Ada S, Seçkin D, Budakoğlu I, Ozdemir FN. *J Am Acad Dermatol* 2005; 53: 149–51.

In this study, 20 patients with uremic pruritus were treated with NB-UVB phototherapy for 6 weeks. Of the 10 who completed the study, 8 showed 50% or greater improvement in pruritus scores. Of the 10 patients who left the study before 6 weeks, 6 were satisfied with their response. In the 6-month follow-up period, 3 of 7 responders who could be examined were in remission, whereas in the remaining 4 responders, pruritus recurred within a mean time interval of 2.5 months.

Generalized pruritus treated with narrowband UVB

Seçkin D, Demircay A, Akin O. *Int J Dermatol* 2007; 46: 367–70.

Fifteen patients with uremic pruritus included in the analysis of this open-label trial were treated with NB-UVB phototherapy three times weekly with a mean number of 22 treatments and a mean cumulative UVB dose of 24,540 mJ/cm². These patients showed greater than 50% improvement in visual analog and pruritus grading scores. Of the 6 patients who were followed up at a mean time of 5.3 months, 2 remained in remission.

Ultraviolet phototherapy of uremic pruritus. Long-term results and possible mechanism of action

Gilchrest BA, Rowe JW, Brown RS, Steinman TI, Arndt KA. *Ann Intern Med* 1979; 91: 17–21.

This is the classic study of 38 patients with uremic pruritus treated with UVB phototherapy. A comparison of three schedules varying from one to three treatments weekly showed that the percentage of patients responding was not influenced by frequency of UVB exposure, although patients treated more intensively improved faster. Patients receiving only half-body treatments improved as well, indicating a systemic rather than local effect. Overall, 32 of 38 patients improved after a course of six or eight UVB exposures.

Gabapentin: a promising drug for the treatment of uremic

pruritus

Naini AE, Harandi AA, Khanbabapour S, Shahidi S, Seirafiyan S, Mohseni M. Saudi J Kidney Dis Transpl 2007; 18: 378–81.

In this double-blind, placebo-controlled trial of 34 hemodialysis patients, those who received gabapentin 400 mg twice weekly after hemodialysis sessions for 4 weeks reported significantly improved pruritus score compared with placebo.

Gabapentin therapy for pruritus in haemodialysis patients: a randomized, placebo-controlled, double-blind trial

Gunal AI, Ozalp G, Yoldas TK, Gunal SY, Kirciman E, Celiker H. Nephrol Dial Transplant 2004; 19: 3137–9.

In this double-blind, placebo-controlled, crossover study of 25 hemodialysis patients, those who received gabapentin 300 mg three times a week after each hemodialysis session for 4 weeks reported a significantly improved pruritus score compared with placebo.

Use of pregabalin in the management of chronic uremic pruritus

Shavit L, Grenader T, Lifschitz M, Slotki I. J Pain Symptom Manage 2013; 45: 776–81.

This prospective observational study in a cohort of 12 patients showed significant improvement in long-standing uremic pruritus as measured by mean VAS scores 1, 4, and 24 weeks after initiation of pregabalin.

Comparison of pregabalin with ondansetron in treatment of uraemic pruritus in dialysis patients: a prospective, randomized, double-blind study

Yue J, Jiao S, Xiao Y, Ren W, Zhao T, Meng J. Int Urol Nephrol 2015; 47: 161–7.

In this 12-week prospective, randomized, double-blind trial, patients in the pregabalin group experienced significantly reduced severity of pruritus compared with patients in the ondansetron and the placebo groups. Final pruritus scores were not different between the ondansetron and the placebo groups.

Pregabalin versus gabapentin in the treatment of neuropathic pruritus in maintenance hemodialysis patients: a prospective crossover study

Solak Y, Biyik Z, Atalay H, Gaipov A, Guney F, Turk S, et al.

Nephrology 2012; 17: 710–7.

Randomised crossover trial of naltrexone in uraemic pruritus

Peer G, Kivity S, Agami O, Fireman E, Silverberg D, Blum M, et al. Lancet 1996; 348: 1552–4.

Naltrexone 50 mg daily was given to 15 hemodialysis patients with severe resistant pruritus. All 15 patients responded to treatment, and the median pruritus scores were significantly reduced compared with baseline values.

Naltrexone does not relieve uremic pruritus: results of a randomized placebo-controlled crossover study

Pauli-Magnus C, Mikus G, Alscher DM, Kirschner T, Nagel W, Gugeler N, et al. J Am Soc Nephrol 2000; 11: 514–9.

In this double-blind, placebo-controlled, crossover study, 23 patients taking naltrexone 50 mg daily showed no difference in reported pruritus and intensity of pruritus scores compared with placebo.

This study contradicts the previous one. Why is not clear.

Kappa-opioid system in uremic pruritus: multicenter, randomized, double-blind, placebo-controlled clinical studies

Wikström B, Gellert R, Ladefoged SD, Danda Y, Akai M, Ide K, et al. J Am Soc Nephrol 2005; 16: 3742–7.

In this multicenter, randomized, double-blind, placebo-controlled study involving 144 patients with uremic pruritus, those who received posthemodialysis intravenous nalfurafine for 2 to 4 weeks reported significant reductions in itch intensity, sleep disturbances, and excoriations compared with placebo.

Nalfurafine hydrochloride for the treatment of pruritus

Inui S. Expert Opin Pharmacother 2012; 13: 1507–13.

A review that describes the pharmacology, efficacy, and potential adverse effects of nalfurafine hydrochloride, a combined mu-opioid receptor antagonist and kappa-opioid agonist, in the treatment of pruritus. It is not yet available in the United States.

Second-Line Therapies

• Zinc sulfate	A
• Capsaicin 0.03% cream	A
• Acupuncture: Quchi (LI11) acupoint	A
• Homeopathic treatment with verum	A

Zinc sulfate for relief of pruritus in patients on maintenance hemodialysis

Najafabadi MM, Faghihi G, Emami A, Monghad M, Moeenzadeh F, Sharif N, et al. *Ther Apher Dial* 2012; 16: 142–5.

In this double-blind, randomized, placebo-controlled trial, 40 adults with end-stage renal disease (ESRD) on maintenance hemodialysis in two Iranian university hospitals were randomized to receive either zinc sulfate (440 mg/day) or placebo for 2 consecutive months. Pruritus was assessed at baseline and then every 2 weeks using a numeric rating scale from 0 to 10 until 1 month after treatment. Pruritus was decreased in both groups after treatment, but there was a significantly greater decrease in the zinc sulfate group compared with placebo ($p = 0.018$).

Topical capsaicin therapy for uremic pruritus in patients on hemodialysis

Makhlough A, Ala S, Haj-Heydari Z, Kashi Z, Bari A. *Iran J Kidney Dis* 2010; 4: 137–40.

In this randomized, double-blind, crossover clinical trial, 34 patients on hemodialysis with uremic pruritus were randomized to receive capsaicin 0.03% cream or placebo for 4 weeks. After a 2-week washout period, subjects crossed over arms. After each week of treatment, pruritus scores in the capsaicin arm were significantly ($p < 0.001$) improved compared with the placebo group. A repeated measurement test showed that the decrease in pruritus severity in the capsaicin group was greater than in the placebo group during the treatment period ($p < 0.001$).

Acupuncture in haemodialysis patients at the Quchi (LI11)

acupoint for refractory uraemic pruritus

Che-Yi C, Wen CY, Min-Tsung K, Chiu-Ching H. Nephrol Dial Transplant 2005; 20: 1912–5.

In this randomized controlled study involving 40 patients with refractory uremic pruritus, those who received acupuncture applied unilaterally at the Quchi (LI11) acupoint thrice weekly for 1 month reported significantly reduced pruritus scores after acupuncture and at 3-month follow-up compared with acupuncture applied at a nonacupoint.

Effects of homeopathic treatment on pruritus of haemodialysis patients: a randomised placebo-controlled double-blind trial

Cavalcanti AM, Rocha LM, Carillo R Jr, Lima LU, Lugon JR. Homeopathy 2003; 92: 177–81.

In this double-blind, placebo-controlled, randomized trial of 28 hemodialysis patients, those who received verum reported significantly reduced pruritus scores throughout the trial compared with placebo. Patients reported a 49% reduction in the pruritus score at the end of the study.

Third-Line Therapies

• Cholestyramine	A
• Activated charcoal	D
• Thalidomide	B
• Parathyroidectomy	B

Cholestyramine in uraemic pruritus

Silverberg DS, Iaina A, Reisin E, Rotzak R, Eliahou HE. Br Med J 1977;

1: 752–3.

This randomized, placebo-controlled, double-blind study showed cholestyramine 5 g twice daily for 4 weeks improved pruritus in four of five subjects.

Relief of idiopathic generalized pruritus in dialysis patients treated with activated oral charcoal

Pederson JA, Matter BJ, Czerwinski AW, Llach F. Ann Intern Med 1980; 93: 446–8.

Oral charcoal 6 g daily for 8 weeks improved pruritus in 10 of 11 hemodialysis patients in this double-blind, placebo-controlled, crossover study.

Thalidomide for the treatment of uremic pruritus: a crossover randomized double-blind trial

Silva SR, Viana PC, Lugon NV, Hoette M, Ruzany F, Lugon JR. Nephron 1994; 67: 270–3.

Twenty-nine patients in this study were assigned to receive thalidomide or placebo at bedtime for 7 days. After a washout period of 7 days, drugs were crossed over. Over half of the patients had a greater than 50% reduction in pruritus while on thalidomide.

A study on pruritus after parathyroidectomy for secondary hyperparathyroidism

Chou F, Ji-Chen H, Shun-Chen H, Shyr-Ming S. J Am Coll Surg 2000; 190: 65–70.

Thirty-seven dialysis patients with secondary hyperparathyroidism underwent parathyroidectomy. Twenty-two patients had pruritus before parathyroidectomy, and in those patients with itch, pruritus scores improved significantly. This was accompanied by improvement in the calcium–phosphorus product.

Itch associated with malignancy

Pruritus associated with malignancy is a common occurrence among patients with lymphomas and advanced malignancy. It may be one of the most bothersome symptoms to a cancer patient, and its management is challenging. The best evidence to date in the treatment of pruritus associated with malignancy exists for *paroxetine*.

First-Line Therapy

• Paroxetine	A
--------------	---

Paroxetine in the treatment of severe nondermatologic pruritus: a randomized, controlled trial

Zylicz Z, Krajnik M, Sorge AA, Costantini M. J Pain Symptom Manage 2003; 26: 1105–12.

This is a prospective, randomized, double-blind, placebo-controlled, crossover study involving 26 patients, of whom 17 had solid tumors, 4 had hematologic malignancies, and 5 had various nonmalignant conditions associated with pruritus. Patients reported significantly reduced pruritus intensity scores during treatment with paroxetine 20 mg daily. Nine of 24 patients completing the study experienced at least 50% reduction of intensity of pruritus. Onset of antipruritic action was observed usually after 2 to 3 days.

Second-Line Therapies

• Mirtazapine	E
• Butorphanol	E

Mirtazapine for pruritus

Davis MP, Frandsen JL, Walsh D, Andresen S, Taylor S. Pain Symptom Manage 2003; 25: 288–91.

In this case series of four patients with cholestasis, lymphoma, and

uremic pruritus, each patient showed improvement in pruritus with mirtazapine 15 to 30 daily.

Butorphanol for treatment of intractable pruritus

Dawn AG, Yosipovitch G. J Am Acad Dermatol 2006; 54: 527–31.

In a patient with non-Hodgkin lymphoma and intractable pruritus, butorphanol 1 mg daily improved itch and sleep after only one dose without improvement of daytime itch. After undergoing chemotherapy with concurrent butorphanol 3 mg daily, the patient's pruritus resolved as the cancer regressed. Butorphanol is currently unavailable in the United States.

Itch associated with hematologic disorders

Pruritus associated with hematologic diseases (e.g., polycythemia vera and myelodysplastic syndrome) is often severe and intractable to the limited therapies available. *Phototherapy* remains the primary line of therapy for these patients.

First-Line Therapies

• Narrowband UVB phototherapy	D
• Psoralen photochemotherapy	D

Narrowband (TL-01) ultraviolet B phototherapy for pruritus in polycythaemia vera

Baldo A, Sammarco E, Plaitano R, Martinelli V, Monfrecola. Br J Dermatol 2002; 147: 979–81.

In this series, 10 patients with pruritus associated with polycythemia vera were treated with NB-UVB phototherapy thrice weekly. In 8 of 10 patients, complete remission of pruritus occurred within 2 to 10 weeks of treatment and a median cumulative dose of 5371.46 mJ/cm².

Efficacy of photochemotherapy on severe pruritus in polycythemia vera

Jeanmougin M, Rain JD, Najean Y. Ann Hematol 1996; 73: 91–3.

In this series, 10 of 11 patients with polycythemia rubra vera improved with psoralen photochemotherapy, and maintenance therapy was generally necessary.

The efficacy of psoralen photochemotherapy in the treatment of aquagenic pruritus

Menagé HD, Norris PG, Hawk JLM, Greaves MW. Br J Dermatol 1993; 129: 163–5.

In this series of five patients with aquagenic pruritus, psoralen photochemotherapy was an effective treatment. One patient had associated polycythemia rubra vera, and another had myelodysplastic syndrome. Maintenance therapy or a further course of PUVA was necessary to maintain remission.

Second-Line Therapies

• Paroxetine	D
• Fluoxetine	E

Selective serotonin reuptake inhibitors are effective in the treatment of polycythemia vera-associated pruritus

Tefferi A, Fonseca R. Blood 2002; 99: 2627.

In this series of patients with polycythemia vera–associated intractable pruritus, nine were treated with paroxetine 20 mg daily and one received fluoxetine 10 mg daily. All patients had a favorable initial response, and eight patients experienced complete or near-complete resolution of pruritus. Response occurred within 48 hours in most patients.

Third-Line Therapy

• Pregabalin	E
--------------	---

Pregabalin in the treatment of chronic pruritus

Ehrchen J, Ständer S. J Am Acad Dermatol 2008; 58: S36–7.

Two patients with aquagenic pruritus and one with idiopathic pruritus who had severe generalized itch were all treated with pregabalin initially at 75 mg twice daily and increased to 150 mg twice daily. The patients reported greater than 70% reduction of symptoms 5 to 8 weeks after starting therapy. The longest follow-up period was 6 months, at which time the effects of pregabalin were stable. Weight gain, somnolence, dizziness, and peripheral edema were observed side effects.

Miscellaneous diseases associated with itch

Miscellaneous diseases associated with itch include psychogenic pruritus, nocturnal itch, HIV, hydroxyethyl starch deposition–induced pruritus, and essential pruritus of the elderly (Willan itch).

Paroxetine in a case of psychogenic pruritus and neurotic excoriations

Biondi M, Arcangeli T, Petrucci RM. Psychother Psychosom 2000; 69: 165–6.

In this case 20 to 30 mg daily of paroxetine reduced the sensation of itch in a patient with psychogenic pruritus and neurotic excoriations.

Mirtazapine for reducing nocturnal itch in patients with chronic pruritus: a pilot study

Hundley JL, Yosipovitch G. J Am Acad Dermatol 2004; 50: 889–91.

In this open, uncontrolled pilot study of three patients with

inflammatory skin diseases and severe nocturnal pruritus, mirtazapine, a noradrenergic and specific serotonergic antidepressant, improved symptoms.

UVB phototherapy is an effective treatment for pruritus in patients infected with HIV

Lim HW, Vallurupalli S, Meola T, Soter NA. *J Am Acad Dermatol* 1997; 37: 414–7.

Twenty-one HIV-positive patients with pruritus treated with UVB phototherapy three times weekly reported reduced pruritus scores. A mean number of 20.7 ± 2.3 treatments resulted in maximal improvement.

Oxatomide in the treatment of pruritus senilis. A double-blind placebo-controlled trial

Dupont C, de Maubeuge J, Kotlar W, Lays Y, Masson M. *Dermatologica* 1984; 169: 348–53.

In this double-blind, placebo-controlled study involving 35 patients with pruritus senilis, oxatomide 30 mg twice daily for 2 months resulted in complete suppression or marked improvement of symptoms in 79% of treated patients.

Efficacy and safety of naltrexone, an oral opiate receptor antagonist, in the treatment of pruritus in internal and dermatological diseases

Metze D, Reimann S, Beissert S, Luger TA. *J Am Acad Dermatol* 1999; 41: 533–9.

Fifty patients with itch of various causes were treated with naltrexone 50 milligrams daily; 70% of patients achieved a significant therapeutic response as demonstrated by improvement in a VAS for itch. Seventeen patients developed peripheral neuropathy.

Transnasal butorphanol for the treatment of opioid-induced pruritus unresponsive to antihistamines

Duntzman E, Karanikolas M, Filos KS. *J Pain Symptom Manage* 1996; 12: 255–60.

All six patients with opioid-induced pruritus who received 2 mg intranasal butorphanol every 4 to 6 hours reported significant relief from pruritus. Five patients noted an improvement within 15 minutes.

Butorphanol for treatment of intractable pruritus

Dawn AG, Yosipovitch G. J Am Acad Dermatol 2006; 54: 527–31.

Butorphanol, a kappa-opioid agonist and mu-opioid antagonist, resulted in rapid and marked improvement in five patients with intractable pruritus associated with inflammatory skin diseases or systemic diseases. The combination of a kappa-opioid agonist with a mu-opioid antagonist holds out much promise. Oral preparations are under investigation.

Antipruritic treatment with systemic μ -opioid receptor antagonists: a review

Phan NQ, Bernhard JD, Luger TA, Ständer S. J Am Acad Dermatol 2010; 63: 680–8.

This review discusses the antipruritic action of systemic mu-opioid receptor antagonists, including naloxone, nalmefene, and naltrexone, which are used in the treatment of chronic cholestatic and several other types of pruritus.

Systemic kappa opioid receptor agonists in the treatment of chronic pruritus: a literature review

Phan NQ, Lotts T, Antal A, Bernhard JD, Ständer S. Acta Derm Venereol 2012; 92: 555–60.

An overview of the promising role of kappa-opioid receptor agonists in the pathophysiology and treatment of pruritus.

Pruritus ani

Michal Martinka, and Gabriele Weichert

Pruritus ani is characterized by intensely pruritic perianal skin. It is classified into primary (idiopathic) and secondary (induced by an underlying cause). It is common, with incidence ranging from 1% to 5%. Chronic cases are associated with significant discomfort, embarrassment, and sleep disturbance.

Management Strategy

Diagnosis requires a detailed search for a potential cause. Categories include inflammatory (atopic dermatitis, psoriasis, or lichen sclerosus), infectious (bacterial, viral, fungal, parasitic, or infestations), systemic disease (diabetes, thyroid disorders, hepatic disorders, leukemia, and lymphoma), local irritants (fecal contamination, moisture, soaps, diet, topical or systemic medications), and colorectal and anal causes (hemorrhoids, anal fissures, diarrhea). A complete history, including diet, bowel movements, cleansing techniques, and treatments, is prudent, and patients should undergo a total body skin examination to identify other underlying etiologies. With this approach, most causes of secondary pruritus can be identified and treated. It is the patient in whom none of these factors are identified who suffers from idiopathic pruritus ani.

Overcleansing is not uncommon and may be irritating or sensitizing. Potential topical sensitizers should be stopped. *Avoidance of toilet paper* after bowel movements can be helpful, as this may be abrasive. Many patients suffer from low-grade fecal incontinence. This is often evident on examination of the underclothes or of the perianal skin.

Therapy is directed at the underlying cause. However, if secondary causes have been ruled out and a diagnosis of primary pruritus ani has been made, empiric treatment is directed toward proper anal hygiene, removal of common irritators, and protection of perianal skin. Advise patients to cleanse the perianal skin twice a day and after bowel movements using cotton balls or cotton squares (make-up removal pads) moistened with warm water or a liquid cleanser and then dried with a hair drier on “cool” setting. Patients with low-grade fecal incontinence should perform this routine several times a day. *Cleansing* has been shown to be as effective as topical steroids. A short (few weeks) course of a *low- to midpotency topical steroid* is recommended. Caution must be taken with prolonged high-potency steroid use, as this area is prone to atrophy. *Topical tacrolimus* may be used in clearance or maintenance treatment. After cleansing, *topical zinc paste* can limit the degree of irritant dermatitis in patients with fecal incontinence. A *sedating antihistamine* may provide welcome sleep in the early weeks of treatment.

A *biopsy* should be performed if the diagnosis is in doubt or the condition is not responding to treatment. If a patient fails to improve, lower gastrointestinal investigations should be considered to rule out neoplastic disease. *Patch testing* should be performed in patients who

fail to improve. Avoidance of caffeine and increased dietary fiber intake may be helpful. For a second-line therapy, *topical capsaicin* can be used. Capsaicin will initially cause perianal irritation in most patients during therapy. Finally, *intralesional steroid* injections to the perianal skin may be considered. *Intradermal methylene blue* injections are reported to damage dermal nerve endings and provide relief. *Injection with phenol in almond oil* has been reported to be beneficial.

Specific Investigations

- Bacterial swab
- Fungal microscopy and culture
- Biopsy
- Skin scrapings for scabies
- Patch testing
- Gastrointestinal investigations

Pruritus ani: diagnosis and treatment

Nasseri Y, Osborne M. *Gastroenterol Clin North Am* 2013; 42: 801–13.

Over 100 different etiologies have been reported to cause pruritus ani.

Allergic contact dermatitis in patients with anogenital complaints

Bauer A, Geier J, Elsner P. *J Reprod Med* 2000; 45: 649–54.

A 5-year collection of patients demonstrated an increased incidence of benzocaine and (chloro-)methyl-isothiazolinone allergy. A diagnosis of allergic contact dermatitis was made in 34.8%. The authors recommend using the standard tray plus dibucaine, propolis, bufexamac, and other ingredients gained from the patient's history.

Pruritus ani as a manifestation of systemic contact dermatitis: resolution with dietary nickel restriction

Silvestri D, Barmettler S. *Dermatitis* 2011; 22: 50–5.

A patient with recalcitrant pruritus ani was found to be highly nickel allergic on patch testing. A low-nickel diet led to resolution of his symptoms, and recurrence appeared with rechallenge.

Abnormal transient internal sphincter relaxation in idiopathic pruritus ani: physiological evidence from ambulatory monitoring

Farouk R, Duthie GS, Pryde A, Bartolo DC. Br J Surg 1994; 81: 603–6.

Abnormal rectal sphincter tone was demonstrated in patients with pruritus ani. This may well be the contributing factor in patients who have occult fecal leakage as a component of their itch.

Pruritus ani. Causes and concerns

Daniel GL, Longo WE, Vernava AM. Dis Colon Rectum 1994; 37: 670–4.

In this series of 104 patients, 52% had anorectal disease (including hemorrhoids, anal fissures, genital warts, and fistulas) and 23% had a colorectal neoplasm found with investigations. In those without neoplasia, there was a direct correlation between increased caffeine intake and severity of irritation. Patients with primary pruritus ani improved with dietary restrictions (not defined), dietary fiber, steroid creams, and drying agents.

First-Line Therapies

• Topical corticosteroids	A
• Topical tacrolimus	A
• Hygiene	B

1% hydrocortisone ointment is an effective treatment of pruritus ani: a pilot randomized control crossover trial

Al-Ghnaniem R, Short K, Pullen A, Fuller LC, Rennie JA, Leather AJ. Int J Colorectal Dis 2007; 22: 1463–7.

Nineteen patients were randomized to 1% hydrocortisone in paraffin twice daily or paraffin base for 2 weeks followed by crossover treatment for 2 weeks. Visual analog score (VAS) showed a 68% reduction with steroid treatment.

Randomized study of topical tacrolimus ointment as possible

treatment for resistant idiopathic pruritus ani

Suys E. J Am Acad Dermatol 2012; 66: 327–8.

Twenty-one patients were randomized to 0.1% tacrolimus versus petrolatum twice daily for 4 weeks with a further 4-week crossover phase. There was improvement in itch intensity and frequency on tacrolimus, but Dermatology Life Quality Index (DLQI) was not significantly different compared with placebo. One patient had a temporary burning sensation.

Idiopathic perianal pruritus: washing compared with topical corticosteroids

Oztas MO, Oztas P, Onder M. Postgrad Med J 2004; 80: 295–7.

In this study, 28 patients applied topical methylprednisolone cream twice daily for 2 weeks. In a separate group, 32 patients were instructed to cleanse the perianal area twice daily with a liquid cleanser. Effectiveness was similar at 92.3% in the first and 90.6% in the second group.

Second-Line Therapies

• Topical capsaicin	A
• Topical acrylate barrier	D

Topical capsaicin: a novel and effective treatment for idiopathic intractable pruritus ani: a randomised, placebo controlled, crossover study

Lysy J, Sistiery-Ittah M, Israelit Y, Shmueli A, Strauss-Liviatan N, Mindrul V, et al. Gut 2003; 52: 1323–6.

Capsaicin 0.006% cream was applied three times a day for 1 month. The control treatment was 1% menthol cream. Of 44 patients, 31 experienced partial relief of symptoms ($p < 0.0001$). All patients experienced some degree of perianal burning. The menthol cream was not effective.

A liquid-forming acrylate cream for the treatment of anal pruritus

Tomi N, Weiser R, Strohal R, Mittlboeck M. Br J Nurs 2012; 21: 98–102.

Twenty-eight patients applied an acrylate protection cream (Cavilon Durable Barrier Cream, 3M) daily for 3 weeks. There was an 80% reduction in VAS.

Third-Line Therapies

• Intralesional corticosteroids	C
• Intradermal methylene blue	B
• Subcutaneous phenol injection	B

The use of intralesional triamcinolone hexacetonide in the treatment of idiopathic pruritus ani

Minvielle L, Hernandez VL. Dis Colon Rectum 1969; 12: 340–3.

Nineteen patients were treated weekly for 4 weeks at 5 to 20 mg/week. Nine of 19 (73.6%) patients had excellent progress, 2 of 19 reported fair improvement, and 3 failed to improve. No perianal atrophy was noted at the end of 4 weeks.

Long-term results of single intradermal 1% methylene blue injection for intractable idiopathic pruritus ani: a prospective study

Samalavicius N, Poskus T, Gupta R, Lunevicius R. Tech Coloproctol 2012; 16: 295–7.

Ten patients received 15 mL of 1% methylene blue intradermally; all had initial resolution of symptoms at 4 weeks. At 60-month follow-up, six patients felt better than baseline or had complete resolution of symptoms.

Methylene blue has been shown by electron microscopy to cause damage to dermal nerve endings. This is the proposed mechanism of action for this modality.

A new concept of the anatomy of the anal sphincter mechanism and the physiology of defecation. XXIII. An injection technique for the treatment of idiopathic pruritus ani

Shafik A. Int Surg 1990; 75: 43–6.

In this series, 67 patients were treated with an injection of 5% phenol in almond oil: 62/67 (92.4%) experienced complete relief. Five patients relapsed. Repeat injection led to cure.

Pruritus vulvae

Ginat W. Mirowski, and Bethanee J. Schlosser

Pruritus vulvae is the external sensation of itching that results in a need to scratch or rub the vulva. Primary findings are representative of the underlying disease process and may include macular or papular erythema, cigarette-paper atrophy, dyspigmentation, and erosion; scale is rarely seen due to the inherently moist environment. Secondary findings include lichenification, erosions, fissures, and pigmentary changes from scratching. Vaginal discharge is normal.

Pruritus vulvae may be primary (essential), secondary, or multifactorial. Essential pruritus vulvae is the condition in which no etiology can be identified. Regardless of etiology, long-standing pruritus vulvae may result in lichenification indistinguishable from lichen simplex chronicus.

Management Strategy

Pruritus vulvae describes a symptom that may be both psychologically distressing and socially embarrassing. An underlying etiology should be sought by obtaining a thorough history and performing a mucocutaneous physical examination. Examination findings may include both primary and secondary. A personal or family history of any inflammatory dermatosis may direct the differential diagnosis. Secondary pruritus vulvae may be caused by infections, dermatoses, systemic diseases, and malignant or premalignant lesions. Appropriate treatment should be instituted.

If no etiology is identified, then symptomatic relief is the goal of therapy. The tenets of treatment are to interrupt the itch–scratch cycle, restore the skin barrier, and minimize impact on quality of life.

The mainstay of treatment of pruritus vulvae is to *identify and remove all suspected local irritants and allergens*. The patient should be instructed to discontinue all local products, including soaps, personal hygiene products, sanitary pads, medications (complementary/alternative, nonprescription, and prescription), and occlusive/synthetic clothing. The patient should bathe with lukewarm (not hot) water, pat (not rub) dry, wipe from front to back, change underpants daily, and launder clothing using a double-rinse cycle. The patient may resist these measures, as they may believe in the need to have a “clean” vulva and that natural secretions and odors are offensive or the cause of their symptoms. The patient may develop elaborate hygiene regimens that contribute to local irritation and contact sensitivity and may confound or be the primary cause of persistent pruritus. Toilet (tissue) paper and commercial wipes may contribute to local irritation. Furthermore, both may contain allergens such as formaldehyde, benzalkonium chloride, and fragrance that could contribute to persistent pruritus. Talc and other powders may combine with sweat to cause mechanical irritation much like fine sandpaper. Furthermore, there is increasing evidence regarding an association between the use of talc in the genital area and ovarian

cancer. Urine, stool, sweat, and cervical or vaginal secretions may contribute to local irritation. Urinary incontinence and contact with stool should be addressed. Cotton washcloths, cool Sitz baths, and use of fragrance-free feminine hygiene products should be advocated.

The use of *barrier petrolatum- and zinc-based ointments*, used to prevent diaper rash in both children and adults, helps to seal in moisture and protect the affected skin. In low-estrogen states (postpartum, lactation, perimenopause, and postmenopause), the use of topical or systemic estrogen helps restore vaginal and vulvar mucosal barrier function.

Systemic or topical corticosteroids are used to reduce inflammation. Ointment-based formulations are preferred for the following reasons: 1) ointments are water insoluble and will not be diluted in the naturally moist vulvar environment; 2) ointments serve as a barrier against further external chemical and physical insults; and 3) ointments generally contain fewer inactive ingredients, which may be potential irritants or allergens. Topical preparations may contribute to allergic or irritant contact dermatitis due either to inactive ingredients or, less commonly, due to the corticosteroid itself. Corticosteroid ointment, used sparingly, should be applied once or twice a day. Close clinical supervision is necessary to minimize adverse effects such as striae, folliculitis, and atrophy. Systemic agents are used to treat infections and to provide symptomatic relief of pruritus in order to limit complications of local agents. *Intralesional triamcinolone acetonide injection* and *systemic corticosteroids* may be effective for recalcitrant pruritus.

Although corticosteroids reduce pruritus, they are often not sufficient to interrupt the itch–scratch cycle. Nightly *sedating antihistamines* such as hydroxyzine or doxepin are recommended. For daytime pruritus, a low-dose *selective serotonin reuptake inhibitor (SSRI)* is advised.

Specific Investigations

- Visual and manual examination of the vulva, vagina, perianal skin, and the complete mucocutaneous integument, including the oral cavity, conjunctivae, total body skin, scalp, and nails
- Palpation of inguinal lymph nodes
- Sensory testing for light touch and Q-Tip evaluation of vulva and

vaginal vestibule

- Saline wet mount of vaginal secretions (cytologic evaluation, presence of lactobacilli, *Trichomonas vaginalis*, bacterial vaginosis)
- Whiff test (bacterial vaginosis)
- KOH (fungi, scabies)
- Vaginal pH (bacterial vaginosis, atrophic vaginitis)
- Tape test (*Enterobius vermicularis*)
- Microbiologic tests (bacterial, fungal, viral)
- Laboratory tests (fasting blood glucose, liver/renal/thyroid function, complete blood count with differential, iron studies including ferritin)
- Biopsy (H&E, direct immunofluorescence, special stains)
- Wood lamp (erythrasma)
- Patch testing (allergic contact dermatitis)
- Colposcopy (in consultation with gynecology, vulvar intraepithelial neoplasia, anal intraepithelial neoplasia)
- Nerve conduction studies (neuropathy)

Box 207.1 Differential Diagnosis of Pruritus Vulvae

Anatomic Alterations

- Fox–Fordyce disease (apocrine duct occlusion)
- Low estrogen states
- Atrophic vulva
- Genitourinary syndrome of menopause (GSM)
- Lactation
- Perimenopause and postmenopause
- Postpartum
- Prepuberty

Infections

- Group A β -hemolytic streptococcus
- Group B β -hemolytic streptococcus
- *Staphylococcus aureus*
- Chlamydia trachomatis
- Erythrasma
- *Gardnerella vaginalis*

- *Neisseria gonorrhoeae*
- *Candida albicans*
- *C. glabrata* (nonalbicans candidiasis)
- *Tinea cruris*
- *Enterobius vermicularis* (pinworm)
- *Phthirus pubis* (pubic lice)
- *Sarcoptes scabiei*
- *Trichomonas vaginalis*
- Herpes simplex virus
- Human papilloma virus
- Human immunodeficiency virus
- *Molluscum contagiosum*
- *Mycobacterium tuberculosis*

Inflammatory Dermatoses

- Allergic contact dermatitis
- Atopic dermatitis
- Dermatographism
- Desquamative inflammatory vaginitis
- Fixed drug eruption
- Irritant contact dermatitis
- Lichen planus
- Lichen sclerosus
- Lichen simplex chronicus
- Papular acantholytic dyskeratosis (Grover disease)
- Plasma cell vulvitis
- Psoriasis
- Seborrheic dermatitis

Neoplasms

- Basal cell carcinoma
- Epidermolytic acanthoma
- Extramammary Paget disease
- Hidradenoma papilliferum
- Langerhans cell histiocytosis
- Melanoma
- Squamous cell carcinoma
- Squamous cell carcinoma in situ (Bowen disease, vulvar intraepithelial neoplasia)
- Syringomas

Systemic Diseases

- Crohn disease
- Diabetes mellitus
- Hepatic failure
- Hypothyroidism
- Iron-deficiency anemia
- Lymphoma
- Polycythemia vera
- Pudendal nerve entrapment
- Renal failure
- Sjögren syndrome

Box 207.2 Common Vulvar Irritants

Bathing

- Bath salts
- Bubble baths
- Excessive or frequent bathing
- Loofahs
- Mesh bath sponges
- Shampoos
- Soaps

Bodily Fluids

- Feces (enzymes)
- Semen
- Sweat
- Urine (ammonia)
- Vaginal discharge (abnormal or increased)

Feminine Hygiene Practices

- Depilatories (chemical, mechanical)
- Douches
- Lubricants
- Panty liners
- Sanitary napkins/pads
- Wipes

Heat

- Hair dryer
- Heating pads

Medications

- Mercaptobenzothiazole
- Thiurams

Sanitary Napkins

- Acetyl acetone
- Formaldehyde
- Fragrance
- Methacrylates

Spermicides

- Hexylresorcinol
- Nonoxynol
- Oxyquinoline sulfate
- Phenylmercuric acetate and butyrate
- Quinine hydrochloride
- Toilet (tissue) paper
- Fragrance
- Formaldehyde

Wet Wipes

- Benzalkonium chloride
- Fragrance
- Methylchloroisothiazolinone/methylisothiazolinone (MCI/MI)

(Modified from Schlosser BJ. Contact dermatitis of the vulva. *Dermatol Clin* 2010; 28, 697–706.)

Anogenital pruritus – an overview

Swamiappan M. *J Clin Diagn Res* 2016; 10: WE10–3.

Excellent review of anogenital pruritus with emphasis on pathophysiology of itch.

Clinical care of vulvar pruritus, with emphasis on one cause, lichen simplex chronicus

Stewart KM. *Dermatol Clin* 2010; 28: 669–80.

An excellent review on the treatment of vulvar pruritus. Extensive clinical differential diagnosis is also discussed. The author focuses on lichen simplex chronicus as a primary etiology of vulvar itch.

An approach to the treatment of anogenital pruritus

Weichert GE. *Dermatol Ther* 2004; 17: 129–33.

Reviews the common causes of acute and chronic anogenital pruritus with a focus on vulvar pruritus. The therapeutic approach to the management of pruritus vulvae in the absence of a clear cause is discussed.

Recurrent vulvovaginal candidosis: focus on the vulva

Beikert FC, Le MT, Koeninger A, Technau K, Clad A. *Mycoses* 2011; 54: e807–10.

A prospective study of 139 women with recurrent vulvovaginal candidiasis revealed a positive correlation between pruritus and *Candida albicans*–positive vulvar fungal cultures (OR 5.4).

Pruritus in diabetes mellitus: investigation of prevalence and correlation with diabetes

Neilly JB, Martin A, Simpson N, MacCuish AC. *Diabetes Care* 1986; 9: 273–5.

Three hundred diabetic and 100 nondiabetic outpatients were evaluated for the presence of generalized and localized pruritus. Pruritus vulvae, the most common symptom, was noted in 18.4% of diabetic women. This was significant ($p < 0.05$), as only 5.6% of nondiabetic women had pruritus vulvae. Symptoms correlated with glycosylated hemoglobin.

Vulvar intraepithelial neoplasia (VIN) diagnostic and therapeutic challenges

Rodolakis A, Diakomanolis E, Vlachos G, Iconomou T, Protopappas A, Stefanidis C, et al. *Eur J Gynaecol Oncol* 2003; 24: 317–22.

A retrospective study of 113 women with VIN revealed that pruritus was the most common presenting symptom (60.1%). Diagnosis was made by colposcopy and biopsy.

Prospective study of patch testing in patients with vulval pruritus

Haverhoek E, Reid C, Gordon L, Marshman G, Wood J, Selva-Nayagam P. *Australas J Dermatol* 2008; 49: 80–5.

Forty-four percent of 43 women with vulval pruritus demonstrated one or more relevant contact allergens.

Patients with vulval pruritus: patch test results

Utas S, Ferahbas A, Yildiz S. *Contact Dermatitis* 2008; 58: 296–8.

Sixteen percent of 50 women with vulval pruritus exhibited one or more relevant allergen reactions. The most common relevant allergens included cosmetics, preservatives, and medications.

Neuropathic scrotal pruritus: anogenital pruritus is a symptom of lumbosacral radiculopathy

Cohen AD, Vander T, Medvendovsky E, Biton A, Naimer S, Shalev R, et al. J Am Acad Dermatol 2005; 52: 61–6.

The role of radiculopathies or pudendal nerve entrapment as a cause of vulvar pruritus is recognized but has not been studied.

Similarities between neuropathic pruritus sites and lichen simplex chronicus sites

Cohen AD, Andrews ID, Medvedovsky E, Peleg R, Vardy DA. Isr Med Assoc J 2014; 16: 88–90.

A large clinical study utilizing nerve conduction studies revealed neuropathy in more than 80% (29 of 36) of patients with anogenital pruritus.

First-Line Therapies

• Oral naltrexone	C
• Topical pimecrolimus	C
• Avoidance of irritants	E
• Hygiene	E
• Topical estrogen	E

Treatment of refractory vulvovaginal pruritus with naltrexone, a

specific opiate antagonist

Bottcher B, Wildt L. Eur J Obstet Gynecol Reprod Biol 2014; 174: 115–6.

Initial report detailing the rapid and complete response to oral naltrexone 50 mg once daily in 5 women otherwise healthy with long-standing vulvovaginal pruritus.

Pimecrolimus 1% cream for pruritus in postmenopausal diabetic women with vulvar lichen simplex chronicus: a prospective non-controlled case series

Kelekci HK, Uncu HG, Yilmaz B, Ozdemir O, Sut N, Kelekci S. J Dermatol Treat 2008; 19: 274–8.

A study of pimecrolimus 1% cream for vulvar lichen simplex chronicus in 12 postmenopausal diabetic women revealed significant improvement in patient-reported pruritus and clinical examination findings.

Efficacy of topical pimecrolimus in the treatment of chronic vulvar pruritus. A prospective case series: a non-controlled, open-label study

Sarifakioglu E, Gumus II. J Dermatol Treat 2006; 17: 276–8.

In 15 patients with chronic vulvar pruritus, pimecrolimus 1% cream applied twice daily for 1 month resulted in complete response in 10 patients and improvement in 3; 2 patients did not return for follow-up.

Contact dermatitis of the vulva

Schlosser BJ. Dermatol Clin 2010; 28: 697–706.

A comprehensive review of irritant and allergic contact dermatitis of the vulva. Avoidance of irritants and potential allergens and the importance of patient education are emphasized.

Lichen simplex chronicus (atopic/neurodermatitis) of the anogenital region

Lynch P. Dermatol Ther 2004; 17: 8–19.

This paper suggests diagnostic tips and a differential diagnosis for vulvar lichen simplex chronicus. The management of lichen simplex chronicus is divided into four categories: identification of any underlying disease, repair of the barrier layer function, reduction of inflammation, and breaking of the itch–scratch cycle. Treatment

options for each category are discussed.

Pruritus vulvae in prepubertal children

Paek SC, Merritt DF, Mallory SB. J Am Acad Dermatol 2001; 44: 795–802.

This paper reviews the causes and treatments of pruritus vulvae in 44 prepubertal girls. Seventy-five percent had nonspecific pruritus. Lichen sclerosus, bacterial infections, yeast infection, and pinworm infestation were seen in a minority of patients. Poor hygiene and irritants are major contributors to pruritus vulvae in this population.

The common problem of vulvar pruritus

Bornstein J, Pascal B, Abramovici H. Obstet Gynecol Surv 1993; 48: 111–8.

The authors of this review article recommend stopping use of all soaps, douches, and perfumed deodorants, keeping the vulva dry, wearing cotton underpants, and avoiding tight pants as basic principles in the treatment of pruritus vulvae.

Vulvovaginal dryness and itching

Margesson LJ. Skin Ther Letter 2001; 6: 3–4.

Vulvar signs of estrogen deficiency and treatment options are discussed.

Second-Line Therapies

• Topical antihistamine	A
• Subcutaneous triamcinolone	B

Efficacy of topical oxatomide in women with pruritus vulva

Origoni M, Garsia S, Sideri M, Pifarotti G, Nicora M. Drugs Exp Clin Res 1990; 16: 591–6.

A double-blind, controlled study evaluated the efficacy of topical oxatomide, an antihistamine available in Europe but not in the United

States, in 29 patients with pruritus vulvae. All patients reported improvement in both intensity and duration of itching. Seven patients experienced complete regression. Results were statistically significant ($p < 0.001$) compared with placebo.

No follow-up studies on the use of topical oxatomide in pruritus vulvae have been published.

Subcutaneous injection of triamcinolone acetonide in the treatment of chronic vulvar pruritus

Kelly RA, Foster DC, Woodruff JD. Am J Obstet Gynecol 1993; 169: 568–70.

A series of 45 patients with chronic pruritus vulvae were treated with subcutaneous intralesional injection of triamcinolone acetonide (total 15–20 mg) into the vulva. Thirty-five experienced relief of pruritus for more than 1 month (mean 5.8 months).

Third-Line Therapies

• Acupuncture	D
• Gonadotropin-releasing hormone	E
• Hypnosis	E

56 cases of chronic pruritus vulvae treated with acupuncture

Huang WY, Guo ZR, Yu J, Hu XL. J Trad Chin Med 1987; 7: 1–3.

Fifty-four of 56 patients with intractable pruritus vulvae experienced symptomatic and clinical improvement with up to seven sessions of acupuncture.

Chronic vulvovaginal pruritus treated successfully with GnRH analogue

Banerjee AK, de Chazal R. Postgrad Med J 2006; 82: e22.

A case report of a 35-year-old woman with intractable cyclical vulvovaginal itching. Suppression of ovulation and empiric treatment with intramuscular injection of leuporelin acetate (a GnRH analog)

for 4 weeks resulted in complete resolution of symptoms. Autoimmune progesterone dermatitis was hypothesized as the primary etiology. The patient declined a progesterone challenge test. Pruritus did not recur with resumption of normal menses.

Hypnosis in a case of long-standing idiopathic itch

Rucklidge JJ, Saunders D. Psychosom Med 1999; 61: 355–8.

A case report of long-standing pruritus vulvae and ani with complete relief of symptoms after training in self-hypnosis.

Effectiveness of treating non-specific pruritus vulvae with topical steroids: a randomized controlled trial

Lagro-Janssen AL, Sluis A. Eur J Gen Pract 2009; 15: 29–33.

A randomized, double-blind, placebo-controlled trial of 50 women with nonspecific vulvar pruritus showed no difference between triamcinolone acetonide 0.1% cream and placebo. Patients with infections and inflammatory dermatoses were excluded.

In contrast to the well-established effectiveness of topical corticosteroids for treating lichen sclerosus–associated pruritus, topical corticosteroids appear to have no benefit in the treatment of nonspecific pruritus vulvae.

Pseudofolliculitis barbae

Gary J. Brauner

Pseudofolliculitis barbae (PFB) is a chronic inflammatory disease of hair-bearing areas induced by shaving or plucking of curved hairs, with resultant transepithelial or transfollicular penetration by the

sharpened hair remnant and a foreign body reaction. It is characterized clinically by papules, papulopustules, focal or diffuse postinflammatory hyperpigmentation, growth grooves, and rarely hypertrophic or keloidal scarring.

Management Strategy

PFB is usually a straightforward clinical diagnosis. As it is induced by hair manipulation (i.e., shaving or plucking), it is not associated with other diseases. Differential diagnoses include true bacterial folliculitis requiring systemic antibiotics and, rarely, yeast folliculitis. Careful clinical inspection and possibly skin biopsy should be performed to rule out granulomatous disease such as sarcoidosis or dental sinusitis in the presence of apparently hypertrophic or keloidal scars. Rarely, ciclosporin therapy may induce a pseudofolliculitis-like condition. Recent French literature cites necrotic folliculitis-like lesions and pathergy as common cutaneous presentations of Behçet syndrome; this “pseudofolliculitis” is not the PFB of ingrowing hairs.

Because this process is induced by shaving, its cure is simple: by *not shaving* or plucking at all and allowing the hairs to grow to beyond 1 cm in length, the disease will spontaneously involute. If a clean-shaven appearance is preferred or deemed necessary by occupational or social demands, management involves three elements: *extraction of the foreign body* by lifting the embedded distal sharpened ends of hairs, *prevention of further embedding* by proper shaving technique or permanent disruption of the follicle’s ability to produce new hair, and *treatment of postinflammatory hyperpigmentation or hypertrophic scarring*.

Embedded hairs should be *lifted*, not plucked, just before shaving. A safety razor set on its “gentlest” setting, or a preadjusted razor such as the PFB Bumpfighter, should be used but with the *opposite hand kept off the face* to prevent skin stretching. Shaving is performed in the direction of hair growth, not against it, again to prevent too-close shaving and transfollicular penetration. A *long presoak* with a hot wet facecloth will allow hairs to swell and lift; a shaving cream that lathers and holds well will keep those hairs saturated and elevated. Shaving must be performed daily; by 2 to 3 days of no shaving, transepidermal reentry penetration will occur. If morning shaving is routine, the affected areas should be gently *buffed* or brushed the evening before with a toothbrush, a rough dry washcloth, or a Buf Puf to loosen hairs about to embed.

Hair clippers will cut hair closely but not so close as to allow transfollicular penetration. Because razor shaving is much closer, clippers should be used at least twice daily to avoid a permanent “5 o’clock shadow.”

Powder chemical depilatories are not practical. They are messy to use, hard to mix accurately, difficult to remove rapidly, and, because they are so irritating, cannot be used more than every 3 days, which already allows PFB to recur. Lotion depilatories are much easier to apply and remove and, being less irritating, can be used every 2 days to produce a satisfactory cosmetic appearance.

Antibiotics are not necessary because this is a sterile foreign body reaction. Irritants such as *retinoic acid* or *glycolic acid* may enhance lifting of hairs and diminish hyperpigmentation.

Several longer wavelength long pulsed *lasers* (alexandrite, 810-nm diode, and Nd:YAG) or intense pulse light (IPL) sources combined with epidermal protective chilling devices can be used to produce dramatic long-lasting remission, even in Fitzpatrick types IV, V, and VI patients and represent a breakthrough treatment for recalcitrant disease. Caution must be employed in dosage selection based on the patient’s underlying skin color, because the hyperpigmented papules themselves may act as highly absorbing hotspots not anticipated by overall lighter skin color and may develop visible burns.

Hyperpigmentation may involute without specific bleaching agents as the inflammation subsides when hairs disappear. Otherwise strategies employing techniques for both epidermal and tattoo-like dermal pigmentation need to be attempted.

Specific Investigation

- Skin biopsy in rare instances

Scar sarcoidosis in pseudofolliculitis barbae

Norton S, Chesser R, Fitzpatrick J. *Military Med* 1991; 156: 369–71.

A man with hilar adenopathy had smooth, firm, purplish papules (lupus pernio) on his face and PFB in his beard area. Biopsies of papules of both the lupus pernio and the PFB revealed noncaseating granulomas consistent with sarcoidosis.

Pseudofolliculitis barbae induced by oral minoxidil

Liew H, Morris-Jones R, Diaz-Cano S, Bashir S. Clin Exp Dermatol 2012; 37: 800–1.

A 61-year-old Afro-Caribbean man with chronic folliculitis of his face and scalp complicated by *Pseudomonas* and enterococcal infection and resulting in papules mimicking keloids, all of which appeared after institution of oral minoxidil (for hypertension) with accompanying increased growth of hair and ceasing only with termination of minoxidil therapy.

Pseudofolliculitis is not demonstrated clinically or histologically in this mistitled paper; folliculitis papillaris with pyoderma is a more appropriate diagnosis.

Disseminated cryptococcosis presenting as pseudofolliculitis in an AIDS patient

Coker L, Swain R, Morris R, McCall C. Cutis 2000; 66: 207–10.

A 42-year-old African American man with AIDS had countless dome-shaped excoriated papules on his trunk, arms, and face, initially diagnosed as folliculitis (not pseudofolliculitis of ingrowing hairs) with biopsy-proven disseminated cutaneous cryptococcosis.

Hyperplastic pseudofolliculitis barbae associated with cyclosporine

Lear J, Bourke JF, Burns DA. Br J Dermatol 1997; 136: 132–3.

A condition resembling keloid reactions in PFB is reported as an unusual reaction to ciclosporin.

Hypertrophic pseudofolliculitis in white renal transplant recipients

Lally A, Wojnarowska F. Clin Exp Dermatol 2007; 32: 268–71.

Five cases of hyperplastic PFB in white patients with renal transplants and ciclosporin immunosuppression are reported with chin involvement in all, but two also had involvement of the nose and occiput, which is otherwise never seen.

The photographs reveal folliculitis papillaris, not PFB.

First-Line Therapies

• Beard growth	D
• Razor shaving technique	D
• Hair clippers	D
• Chemical depilatories	D
• Adjunctive hair extraction	D

Pseudofolliculitis of the beard

Strauss J, Kligman A. Arch Dermatol Syphilol 1956; 74: 533–42.

The first modern description of the pathogenesis of this disease and the rationale for allowing beard growth and spontaneous involution.

Pseudofolliculitis barbae. Medical consequences of interracial friction in the US Army

Brauner G, Flandermeyer K. Cutis 1979; 23: 61–6.

PFB is a minor disease affecting only, and almost all, black people who shave. Due to the continued requirement of the U.S. Army for clean-shaven faces, significant interracial turmoil and animosity have been aroused. Unclear standards of care of the disease and haphazard policing of shaving habits led to a chaotic process, with effective dermatologic care almost paralyzed by the hostile parties. During the Vietnam War era randomly approached lower ranking enlistees and draftees were much more likely to complain about their disease, even if minor, and were more likely to refuse to shave and be unkempt even without permission to grow a beard (in contravention of Army regulations). Career black enlistees are likely to underreport the severity of their disease and not seek medical help, possibly because of fear of continuous harassment and inability to be promoted by their superiors. Lotion depilatories or hair clippers, combined with routine lifting of ingrown hairs, are the most effective treatments, although complete cessation of shaving is required first.

Pseudofolliculitis barbae. 2. Treatment

Brauner G, Flandermeyer K. Int J Dermatol 1977; 16: 520–5.

The disease can be cured only by complete cessation of shaving, but it can be adequately controlled in most patients by carefully shaving the hairs neither too close nor too long and by meticulous lifting out of penetrating hairs.

A variety of practical methods of shaving are described in detail.

Comparative evaluation of men's depilatory composition versus razor in black men

Kindred C, Oresajo C, Yatskayer M, Halder R. Cutis 2011; 88: 98–103.

The authors studied 45 black men over a period of only 1 week with shaving on Saturday of the whole face and then shaving every 2 days on one side of the face and using one of two patient-mixed and applied depilatory pastes or a depilatory cream to the other side. The results confirmed observations by this author (see earlier) 45 years ago that pastes cannot be safely applied for shaving every 2 days without intolerable irritation, and only a depilatory cream can be so used. The depilatories improved tactile and visual roughness and unevenness better than every-other-day shaving, which is not surprising because nondaily shaving promotes the appearance and persistence of PFB.

Use of depilatory cream every 2 days and shaving daily on “virginal skin” after total clearance of PFB by beard growth for 1 month and follow-up for 1 month would have more accurately represented how proper shaving technique is done and provided an accurate comparison.

Pseudofolliculitis barbae and related disorders

Halder R. Dermatol Clin 1988; 6: 407–12.

Not all regimens will work for each patient. This thorough review discusses beards, triple “O” electric clippers, chemical depilatories, safety razors including the foil-guarded system to reduce cutting edge, electric razors including the adjustable three-headed rotary razor, manual lifting of hairs, tretinoin lotion, electrolysis, and surgical depilation.

Pseudofolliculitis barbae and acne keloidalis nuchae

Kelly A. Dermatol Clin 2003; 21: 645–53.

Concise review with good descriptions of various and specific

shaving devices.

Second-Line Therapies

• Retinoic acid	E
• Glycolic acid	B
• Topical clindamycin	A

Pseudofolliculitis of the beard and topically applied tretinoin

Kligman A, Mills O. Arch Dermatol 1973; 107: 5515–2.

Tretinoin solution is described as a useful adjunctive treatment.

Pseudofolliculitis: revised concepts of diagnosis and treatment. Report of three cases in women

Hall J, Goetz C, Bartholome C, Livingood C. Cutis 1979; 23: 798–800.

Three cases are described in black American women. Topical retinoic acid cream was useful in all three.

Twice-daily applications of benzoyl peroxide 5%/clindamycin 1% gel versus vehicle in the treatment of pseudofolliculitis barbae

Cook-Bolden F, Barba A, Halder R, Taylor S. Cutis 2004; 73: 18–24.

Seventy-seven men with 16 to 100 combined papules and pustules on the face and neck were randomized to receive twice-daily benzoyl peroxide 5%/clindamycin 1% (BP/C) gel or vehicle for 10 weeks; 77.3% of the participants were black. All patients were required to shave at least twice a week with a disposable Bumpfighter razor and to use a standardized shaving regimen. At weeks 2, 4, and 6, mean percentage reductions from baseline in combined papule and pustule counts were statistically significantly greater with BP/C gel than with vehicle, but for both were >50% by 10 weeks, particularly in black men. There was a significant change in nonblack men but no

difference between test and controls.

Although 77% of test patients thought they were much better compared with 47% in the control vehicle group, the authors do not explain the remarkable improvement in the control group nor why or how they assume their test product alone “worked.”

Treatment of pseudofolliculitis barbae with topical glycolic acid: a report of two studies

Perricone N. *Cutis* 1993; 52: 232–5.

Two placebo-controlled trials in 35 adult men showed that glycolic acid lotion was significantly more effective than placebo in treating PFB. There was a reduction of over 60% in lesions on the treated side, which allowed daily shaving with little irritation.

Third-Line Therapies

• Laser depilation	A
• Surgical depilation	C

Comparative evaluation of long pulse alexandrite laser and intense pulsed light systems for pseudofolliculitis barbae treatment with one year of follow up

Leheta T. *Indian J Dermatol* 2009; 54: 364–8.

Twenty male patients, allegedly Fitzpatrick types II to IV with pseudofolliculitis, were treated in a double-blind, split-face study by alexandrite laser on one side and intense pulsed light (IPL) on the other while continuing to shave or clip the bearded face. The alexandrite was 755 nm with a 15-mm spot size and was operated at 3 ms eventually at 16 to 18 J/cm², whereas the IPL had a 610- to 1200-nm filter and a 50-mm × 15-mm spot size and was operated at 12 to 15 J/cm², both at 4- to 6-week intervals for four sessions and then 4- to 8-week intervals. Both techniques improved the condition, but the alexandrite laser required an average of seven sessions to reach about

80% improvement in papule count and hyperpigmentation, whereas the IPL-treated side needed 10 to 12 sessions to reach about 50% improvement. Both techniques, however, showed some relapse at 1 year after end of treatments, the IPL more so.

The differences seen may be due to the low settings for both devices; fluences of 20 to 30+ J/cm² are frequently required for effective laser- or IPL-induced follicular fatigue or destruction, especially in type II to IV skin.

Low-fluence 1064-nm laser hair reduction for pseudofolliculitis barbae in skin types IV, V, and VI

Schulze R, Meehan KJ, Lopez A, Sweeney KJ, Winstanley D, Apruzzese W, et al. *Dermatol Surg* 2009; 35: 98–107.

Twenty-two patients with PFB refractory to conservative therapy received five weekly treatments (unlike the customary every 5 weeks) over the anterior neck using a 1064-nm Nd:YAG laser with a 10-mm spot size set at 12 J/cm² and pulse duration 20 ms. Eleven patients demonstrated 83% improvement.

The study was an attempt to reduce energy levels because of high incidence of intolerance to pain in standard settings. The effects were clear, but only temporary, and worsening of PFB after switching to a razor blade as a shaving device suggests an imperfect solution because most blacks shave with razors.

Topical eflornithine hydrochloride improves the effectiveness of standard laser hair removal for treating pseudofolliculitis barbae: a randomized, double-blinded, placebo-controlled trial

Xia Y, Cho S, Howard R, Maggio K. *J Am Acad Dermatol* 2012; 67: 694–9.

Twenty-seven patients (24 black, 3 Caucasian) with Fitzpatrick type II to VI skin were enrolled in a split-neck study comparing four monthly treatments with Nd:YAG laser with 10-mm spot and at 25 to 30 J/cm² with 20- to 30-ms pulse duration with and without twice-daily application of 13.9% eflornithine cream. Shaving was continued. A very significant decrease in countable hairs and papules was evident after only two treatments, and almost no papules were evident at 16 weeks; the eflornithine side was moderately better at each stage. Pain measures were not discussed.

This promising study for shortening treatment course had much too short a follow-up period (i.e., immediately at the end of 16 weeks of treatment). Permanence was not ascertainable. It was peculiar that

the eflornithine side responded more quickly when the medication should be causing a progressively smaller target for the laser, suggesting a more dramatic effect on hair production than just the caliber of hair.

Pseudofolliculitis barbae

Quarles F, Brody H, Johnson B, Badreshia S, Vause SE, Brauner G, et al. *Dermatol Ther* 2007; 20: 133–6.

Anecdotal comments by each member of a large panel of experts concerning useful approaches to the treatment of PFB.

Modified superlong pulse 810 nm diode laser in the treatment of pseudofolliculitis barbae in skin types V and VI

Smith E, Winstanley D, Ross E. *Dermatol Surg* 2005; 31: 297–301.

Ten of 13 patients with type V or VI skin treated with superlong-pulse 810-nm diode laser at 2-week intervals three times with a mean 29 J/cm² and 438 ms for type V and 26 J/cm² at 450 ms for type VI skin and then followed up to only 3 months showed clinical improvement of PFB papules, which was statistically significant. The authors note that the 26 J/cm² maximum tolerable dose may not be sufficient to cause long-term reduction in hair growth. The follow-up of the study was not long enough to determine such reduction either. The authors claim that the ratio of minimal damaging fluence to minimum effective fluence in very dark skin was 1.2:1, versus the safer 1.5 to 2:1 for long-pulse Nd:YAG laser for PFB.

Pseudofolliculitis of the neck and the shoulder: a new effective treatment with alexandrite laser

Valeriant M, Terracina F, Mezzana P. *Plast Reconstruct Surg* 2002; 110: 1195–6.

Two Caucasian men with chronic folliculitis and pseudofolliculitis of the neck and shoulders were treated with 790-nm alexandrite laser for 30 ms with a 10-mm spot size and 16 to 18 J/cm² for four sessions at 6-week intervals. They had a hair loss of 60% to 70% and 90% improvement in PFB, which persisted during 1-year follow-up.

Treatment of pseudofolliculitis with a pulsed infrared laser

Kauvar A. *Arch Dermatol* 2000; 136: 1343–6.

Ten women with Fitzpatrick skin types III to V and a history of pseudofolliculitis on the face, axilla, or groin for at least 1 year had

three consecutive treatments at 6- to 8-week intervals with an 810-nm diode laser and a chill tip at 30 to 38 J/cm² and 20-ms pulse duration. After their last visit all showed more than 75% improvement in the pseudofolliculitis and had a 50% reduction in hair growth. No blistering occurred.

Laser-assisted hair removal for darker skin types

Battle E, Hobbs L. *Dermatol Ther* 2004; 17: 177–83.

The authors carefully review the rationale for use of diode, especially long-pulsed diode, and Nd:YAG lasers for highly pigmented patients, as well as testing, dosing, and cooling precautions to improve patient safety.

Treatment of pseudofolliculitis barbae in skin types IV, V, and VI with a long-pulsed neodymium:yttrium aluminum garnet laser

Ross E, Cooke L, Timko A, Overstreet KA, Graham BS, Barnette DJ. *J Am Acad Dermatol* 2002; 47: 263–70.

Thirty-seven patients with pseudofolliculitis and Fitzpatrick skin types IV, V, and VI were tested with Nd:YAG laser. There was 33%, 43%, and 40% hair reduction on the thigh for the 50-, 80-, and 100-J/cm² fluences, respectively, after 90 days. The highest doses tolerated by the epidermis were 50, 100, and 100 J/cm² for types VI, V, and IV skin, respectively. After testing on the face, mean papule counts after 90 days were 6.95 and 1.0 for the control vs. treatment sites, respectively.

Treatment of pseudofolliculitis barbae using the long-pulse Nd:YAG laser on skin types V and VI

Weaver S, Sagaral E. *Dermatol Surg* 2003; 29: 1187–91.

Twenty subjects with Fitzpatrick type V and VI skin and PFB on the neck or mandible were given two 2-cm × 2-cm treatments with Nd:YAG laser and 10-mm spot size at 40 to 50 ms and 24 to 40 J/cm² 3 to 4 weeks apart, assessed by photographic papule/pustule and hair counts at 1, 2, and 3 months after the final treatment and compared with a neighboring untreated site. The 76% to 90% reduction in the number of papules/pustules was statistically significant. Hair reduction of 80% 1 month after testing diminished to 23% by 3 months.

Although side effects were noted as transient and without blistering, the two illustrated patients both show scarring.

Surgical depilation for the treatment of pseudofolliculitis or local hirsutism of the face: experience in the first 40 patients

Hage J, Bouman F. *Plast Reconstruct Surg* 1991; 88: 446–51.

Forty patients, all but three of whom were Caucasian, were operated on over a 15-year period for local hirsutism ($n = 24$), pseudofolliculitis ($n = 11$), and beard growth ($n = 12$) in transgender procedures. The skin of the affected areas was incised and everted in a dermal–subcutaneous plane, and the hair bulbs were excised. Marked diminution of hair numbers occurred, but 15 patients required further electrolysis. Side effects were significant, with wound edge necrosis in 8, seroma or hematoma in 8, and significant subcutaneous scar formation in 15, which was later preventable by postoperative long-term (at least 3 months) pressure bandages. See also Comments in *Plast Reconstruct Surg* 1992; 90: 332–3.

Pseudoxanthoma elasticum

Roselyn Kellen, and Mark G. Lebwohl

Pseudoxanthoma elasticum (PXE) is a rare autosomal recessive disorder causing abnormal fragmentation and calcification of the elastic fibers in the skin, retina, and cardiovascular system. The primary lesions are small, asymptomatic, yellow papules on the flexural surfaces of the skin. The papules gradually coalesce into plaques, and the skin begins to appear slightly thickened, inelastic, and leatherlike. Ophthalmologic complications include retinal angioid streaks, choroidal neovascularization, and subretinal hemorrhages with resultant scarring causing central vision loss. Cardiovascular

complications include narrowing of the cerebral arteries, intracranial hemorrhage, intermittent leg claudication due to peripheral arterial disease, diminished peripheral pulses, hypertension, and angina pectoris. Gastrointestinal bleeding is reported in about 10% of patients, which may also be due to non-PXE-related factors. The prevalence of PXE in the population is approximately 1:50,000.

Most patients with PXE are found to harbor mutations in ATP-binding cassette sub-family C member 6 (*ABCC6*) gene on chromosome 16p13.1, which codes for an ATP-dependent transmembrane transporter. Hundreds of mutations have been identified, but approximately one third are premature termination mutations. More recently, patients with PXE-like skin changes have been found to have mutations in genes for ectonucleotide pyrophosphatase/phosphodiesterase 1 (*ENPP1*) and gamma-glutamyl carboxylase (*GGCX*). Certain mutations might be more commonly found in Caucasians compared with Asian patients.

Management Strategy

Establishing the diagnosis of PXE may be difficult during the early stages of the disorder. The initial clinical signs appear most commonly during the early teenage years in flexural skin sites on the neck, axillae, antecubital fossae, and groin as variably sized patches of slightly thickened, leathery-looking skin. The diagnosis is often missed during these early years. Larger patches gradually develop with age. Angioid streaks in the retina usually appear later, beginning in the late teens or early twenties. Frank retinal hemorrhages begin most commonly in the fifth decade, causing central vision loss. Cardiovascular changes are rarely noted in children, although rare cases have been reported.

A heart-healthy lifestyle, including a low-cholesterol diet, aerobic exercises, and avoidance of smoking, should be encouraged. Because of the bleeding diathesis, patients should be advised to avoid aspirin and other blood thinners unless essential, as well as contact sports and other activities that increase the risk of eye trauma. There is some evidence that increased dietary calcium results in more rapid progression of the disease, so patients should be encouraged to avoid calcium supplementation and excessive ingestion of milk products. In contrast, experiments with animal models suggest that diets high in magnesium can inhibit tissue mineralization. An interdisciplinary

approach involving dermatologists, retina specialists, and cardiologists is essential. Because this is a rare disease, it is important to provide patients with resources. The following two organizations are good references for patients:

Pseudoxanthoma elasticum (PXE) International: <https://www.pxe.org>

National Association for Pseudoxanthoma Elasticum (NAPE):

<https://www.napeusa.com>

Specific Investigations

- Family history for evidence of similar problems
- Complete skin examination, with special reference to all flexural skin sites and oral mucosa
- General physical examination and routine laboratory tests, including lipid panel, with a focus on risk factors for cardiovascular disease
- A 3- to 4-mm punch biopsy of suspicious lesions and a von Kossa stain to detect calcified elastic fibers to establish a diagnosis
- Retinal examination and photographs for evidence of angioid streaks, neovascularization, and hemorrhages
- Genetic studies on blood may be used to verify the diagnosis of PXE in questionable cases. The tests are expensive and rarely essential to confirm the diagnosis
- Cardiology referral and echocardiogram. There are elastic fibers in cardiac valves so it should not be surprising that cardiac valvular abnormalities, such as mitral valve prolapse, are common in patients with PXE

First-Line Therapies

• Good nutrition; avoidance of trans fats; dietary calcium intake based on patient age and the current recommended dietary intake	B
• Regular exercise program, with care to avoid sports with potential for head or eye injury	B
• Vigorous control of hypertension, abnormal lipid profiles, and other risk factors for cardiovascular disease	C
• Avoid long-term use of anticoagulants (to minimize the risk of ocular, gastrointestinal, and other sources of bleeding)	C
Table Continued	
• Retinal referral and follow-up on regular basis with a retinal specialist familiar with PXE. If early or threatened retinal hemorrhages, consider possible treatment with bevacizumab (Avastin) or ranibizumab (Lucentis)	C
• Cardiology referral; echocardiogram to look for cardiac and valvular abnormalities	C

Long-term effectiveness of intravitreal bevacizumab for

choroidal neovascularization secondary to angioid streaks in pseudoxanthoma elasticum

Finger RP, Charbel IP, Schmitz-Valckenberg S, Holz FG, Scholl HN. Retina 2011; 31: 1268–78.

Intravitreal bevacizumab improved visual acuity, stabilized leakage from active choroidal neovascularizations, and reduced central retinal thickness. There was improvement of visual acuity in early disease and preservation of function in advanced disease. Initiation of therapy as early as possible is important to preservation of vision.

Intravitreal injection of vascular endothelial growth factor inhibitors has dramatically improved the prognosis of PXE eye disease.

Treatment with ranibizumab for choroidal neovascularization secondary to a pseudoxanthoma elasticum: results of the French observational study PIXEL

Ebran JM, Mimoun G, Cohen SY, Grenet T, Donati A, Jean-Pastor M-J, et al. J Fr Ophtalmol 2016; 39: 370–5.

Ranibizumab provided stable visual acuity for at least 2 years in patients with choroidal neovascularization and decreased the frequency of neovascularization relapses. The treatment was well tolerated.

In a different case report, a 54-year-old man with ophthalmologic complications from PXE did not improve after three injections (once a month) of bevacizumab. He received 21 ranibizumab injections (0.5 mg/50 µL), which helped maintain visual acuity over a 6-month period.

Second-Line Therapies

• Cosmetic surgery for removal of objectionable lesions if desired by patient for cosmetic reasons	B
• Observe pregnant women more carefully. Incidence of gastrointestinal hemorrhage is questionably increased during pregnancy	C

Third-Line Therapies

• Sevelamer hydrochloride 800 mg three times daily	A
• Increase in dietary magnesium	E
• Fractional CO ₂ laser	E
• Injectable collagen	E

A randomized controlled trial of oral phosphate binders in the treatment of pseudoxanthoma elasticum

Yoo JY, Blum RR, Singer GK, Stern DR, Emanuel PO, Fuchs W, et al. J Am Acad Dermatol 2011; 65: 341–8.

Sevelamer hydrochloride 800 mg three times daily resulted in reduced calcification of elastic fibers on microscopy and improved clinical scores, but the benefit was not significant compared with placebo.

The placebo was discovered to contain magnesium, which may explain the benefit achieved by the placebo group.

Pseudoxanthoma elasticum, the paradigm of heritable ectopic mineralization disorders: can diet help?

LaRusso J, Li Q, Uitto J. Dtsch Dermatol Ges 2011; 9: 586–93.

A fivefold increase in dietary magnesium inhibited tissue mineralization in a mouse model of PXE.

Animal studies have examined the relationship between magnesium in the diet and mineralization of the vasculature. Mice fed a diet with magnesium oxide supplementation for 2 months had a lower carotid intima-media thickness compared with mice fed a standard diet. In contrast, a low-magnesium diet accelerated calcium deposition.

Pseudoxanthoma elasticum treatment with fractional CO₂ laser

Salles AG, Remigio AF, Moraes LB, Varoni AC, Gemperli R, Ferreira MC. Plast Reconstr Surg Glob Open 2014; 2: e219.

A 32-year-old woman was treated with a fractional CO₂ laser applied to the anterior cervical region (four sessions) and posterior cervical region (five sessions). Significant improvement was noted 1 month after the first session. Two years after the last session, she had improvements in surface irregularities and distensibility.

Pseudoxanthoma elasticum: temporary treatment of chin folds and lines with injectable collagen

Galadari H, Lebwohl M. J Am Acad Dermatol 2003; 49: S265–6.

Two patients with horizontal mental creases received injectable collagen. The first patient received 0.5 mL of collagen (Zyderm II) and showed immediate improvement; however, rhytides and creases recurred 6 months later. The second patient received 1.0 mL of collagen (Zyderm) in 2 sessions (2 weeks apart), and improvement was noted for at least 6 months. Nine months later, she received 1.0 mL intradermal collagen with effects that lasted for only 1 month. A third injection (1.0 mL Zyplast) provided improvement for 4 weeks.

It is likely that any of the new fillers currently available would work as well as injectable collagen.

Acknowledgment

We would like to acknowledge Dr. Kenneth Neldner for his contributions to the previous edition of this chapter.

Psoriasis

Mark G. Lebwohl, and Peter van de Kerkhof

Plaque psoriasis is a common disorder in which environmental factors contribute to the development of sharply demarcated, erythematous, scaling plaques in genetically predisposed individuals. Because there is an overlap in treatments, guttate psoriasis, inverse psoriasis, and impetigo herpetiformis will be discussed under “Management Strategy” next. Erythrodermic psoriasis and pustular psoriasis will be discussed at the end of the chapter. Palmoplantar pustulosis is addressed in its own chapter. Patients should be questioned and examined for psoriatic arthritis, and because of recent

evidence linking psoriasis to cardiovascular disease, risk factors should be addressed. Involvement of rheumatologists or cardiologists may be necessary.

Management Strategy

The treatment of psoriasis must take many factors into account, including the extent of involvement, areas of involvement, the patient's lifestyle, and other health problems and medications. For example, patients who live far from phototherapy centers may not have the option to be treated with psoralen and UVA (PUVA), but a home phototherapy unit can be ordered for patients who can be taught to administer their own UVB therapy. In sunny climates, sun exposure can be added to the therapeutic regimen. If patients are taking medications such as lithium that are known to exacerbate psoriasis, alternatives should be sought. In patients who have had multiple skin cancers, PUVA and ciclosporin should be avoided as they increase the tendency to develop skin cancers; acitretin, which suppresses the development of skin cancers, should be considered for these individuals.

The body surface area affected in patients with psoriasis is important in the selection of therapies. In individuals with less than 5% body surface area involvement, topical therapy is usually started unless the patient has previously failed topical therapy or the psoriasis is debilitating because of the site of involvement. In patients with mild localized plaques, *mild, midpotency, or potent topical corticosteroids* can be prescribed, or other topical agents such as *calcipotriol (calcipotriene), calcitriol, or tazarotene* can be tried. *Anthralin preparations* have fallen into disfavor because they are messy, but they still offer an effective alternative to corticosteroids. In Europe anthralin preparations are used in some daycare centers. Often patients have been using a topical medication that is inadequate as monotherapy, and in such cases combination therapy is warranted. The combination of a superpotent corticosteroid and calcipotriol or tazarotene is often effective when monotherapy with either of the agents does not work, and new formulations that combine betamethasone dipropionate with calcipotriol are available.

Some areas may be limited in extent, but require alternative treatments. For example, involvement of the palms and soles can be debilitating, and these areas are notoriously difficult to treat. Pustular

psoriasis of the palms and soles, for example, only occasionally responds to topical therapy. Although the palms and soles involve only a small percentage of the body surface area, treatment with oral medications or injected medications or *phototherapy* may be warranted. The combination of *acitretin* 25 mg daily with “*bath-PUVA*”—applied by soaking the hands in a water-filled basin to which *methoxsalen* has been added, followed by UVA irradiation—has been used successfully. The *excimer* laser can also be effective for palm and sole psoriasis, as can oral *methotrexate*, *acitretin*, *apremilast*, and *ciclosporin*. Double-blind placebo-controlled trials have demonstrated the efficacy of adalimumab for palm and sole psoriasis, and it is likely that other biologic therapies are effective, though they are not as effective for palms and soles as they are for psoriasis on other parts of the body. Involvement of the scalp is common and requires gels, solutions, sprays, or foams that are not as messy as ointments and creams. *Shampoos containing tars, salicylic acid, or corticosteroids* are useful adjunctive therapies for the scalp. A new home device that delivers narrowband UVB to the scalp through fiber-optic filaments has recently been introduced.

The face and intertriginous sites are highly responsive to topical medications, but are particularly sensitive to the side effects of many topical agents. Topical corticosteroids cause cutaneous atrophy, telangiectasia, and striae. Therefore only milder, safer corticosteroids should be used on the face and intertriginous sites, and alternating with noncorticosteroids may be optimal if psoriasis recurs. The topical immunomodulators *tacrolimus* 0.1% ointment and *pimecrolimus* 1% cream are effective and safe for facial and intertriginous psoriasis, but not as effective on thick plaques on the rest of the body. *Calcipotriol* (50 µg/g) can be irritating on facial or intertriginous psoriasis, but alternative vitamin D analogs such as calcitriol and tacalcitol are less irritating and therefore particularly suited for facial or flexural psoriasis. *Tazarotene* may be too irritating to use on genital skin, but it can be used on the face. The irritation of tazarotene can also be minimized by using it in a regimen with topical corticosteroids.

With 5% to 10% body surface involvement, topical therapy is usually prescribed, but may require the addition of *phototherapy* or *oral medications*. In those with more than 10% body surface involvement, topical therapy may be impractical for all lesions but may provide a useful adjunct to phototherapy or systemic therapy.

Phototherapy with *UVB* has been in use in the treatment of psoriasis for a century and has a proven record of safety and efficacy. It is particularly useful in patients who have responded well to sun exposure. Patients who have failed *UVB* or have not done well with sun exposure often respond to *narrowband UVB*. *PUVA* is one of the most effective treatments for psoriasis and offers long remissions for many patients. Because of its increased risk of cutaneous malignancy, *PUVA* is usually reserved for those who do not achieve adequate remissions with *UVB*.

In patients who have not achieved satisfactory results with these treatments, *low-dose oral retinoids* can be added. *Acitretin* in doses of 10 to 25 mg daily dramatically improves the response to *UVB* and to *PUVA*. By keeping the dose at 25 mg or less, the side effects of *acitretin* can be minimized. For those who are not candidates for *UVB* phototherapy or *PUVA*, *oral methotrexate* is highly effective in combination with other treatments or as monotherapy. It is associated with hepatic fibrosis in some patients, and regular monitoring of liver function tests in addition to blood counts is necessary. Current guidelines in the United States call for periodic liver biopsies in selected patients treated with *methotrexate*. In parts of Europe, the serum level of the aminoterminal propeptide of type III procollagen has been used as a marker for hepatic fibrosis as an alternative to routine use of liver biopsy. *Ciclosporin* is also dramatically effective as monotherapy for psoriasis, but is associated with nephrotoxicity as well as hypertension and a theoretical risk of malignancy with long-term use. Consequently, current guidelines call for limiting use of *ciclosporin* to 1 or 2 years. The most recently approved oral medication for psoriasis, *apremilast*, is another moderately effective option. *Tofacitinib*, an oral agent approved in the United States for rheumatoid arthritis, has also been studied for psoriasis.

In recent years, the ability to create new drugs that target specific parts of the immune system has led to the development of biologic agents for psoriasis. These drugs are not associated with the nephrotoxicity of *ciclosporin* or the hepatotoxicity and bone marrow toxicity of *methotrexate*, but the cost of biologics is often prohibitive. Psoriasis experts are divided on the point at which biologics should be considered. Some consider them first-line therapy when the disease is too extensive for topical therapy. Because of their expense, biologics are used by others only after phototherapy or other systemic therapies have been tried.

Because of their efficacy and safety, use of biologics is growing for psoriasis and for psoriatic arthritis. Agents that block tumor necrosis factor- α (TNF- α), including *etanercept*, *infliximab*, *adalimumab*, *golimumab*, and *certolizumab*, are ideal for patients with psoriatic arthritis. TNF-blocking agents have unique side effects, including the reactivation of latent tuberculosis, exacerbation of multiple sclerosis, and the development of antinuclear antibodies. *Ustekinumab*, a drug that blocks the p40 component of interleukin (IL)-12 and IL-23, has been studied in 45-mg and 90-mg doses; dose elevation can be beneficial in overweight patients. The drug can be administered as infrequently as every 3 months. The recently approved drugs *ixekizumab* and *secukinumab*, which block IL-17, and *brodalumab*, an investigational drug that blocks the IL-17 receptor, are highly effective therapies that can achieve 100% clearing of psoriasis. Other biologic therapies targeting IL-23 are on the way. When all else fails, *combination therapy* using different medications is often effective. Because many of the treatments available are immunosuppressive, side effects of additive immunosuppression must be considered when combining different modalities.

Guttate Psoriasis

Guttate psoriasis is characterized by widespread erythematous, scaling papules. The management of guttate psoriasis is very similar to that of extensive plaque psoriasis. Because streptococcal infection often precedes guttate psoriasis, underlying infection should be sought and treated. Lesions are usually too widespread for topical therapy, so most patients are started on *phototherapy with UVB or narrowband UVB*. If that is ineffective, *oral retinoids* can be added, or patients can be switched to *PUVA*. This form of psoriasis frequently responds to phototherapy, so it is only occasionally necessary to resort to more aggressive second-line or third-line therapies listed later.

Inverse Psoriasis

Patients with inverse psoriasis develop lesions in the axillae, between the buttocks, on the medial aspects of the thighs, and in the umbilicus. These sites are easily treated with *mild topical corticosteroids*, but are

more susceptible to corticosteroid side effects such as atrophy and formation of striae. Consequently, nonsteroidal treatments can be attempted. *Calcipotriol* (50 µg/g) can be irritating on intertriginous sites but is nevertheless effective. *Other vitamin D analogs* (*calcitriol*, *tacalcitol*) cause less irritation. *Tazarotene* can be used on the face, but is usually too irritating to use in the axillae or groin. *Tars and anthralin* are likewise irritating in intertriginous sites. *Topical tacrolimus ointment* and *pimecrolimus cream*, albeit not approved for psoriasis, are highly effective for facial and intertriginous psoriasis, but less effective for thick plaques elsewhere on the body. Topical phosphodiesterase inhibitors and Janus kinase inhibitors are likely to be introduced for psoriasis, and these may be effective for facial and intertriginous psoriasis without the atrophogenicity of corticosteroids.

Impetigo Herpetiformis

Impetigo herpetiformis is characterized by a generalized pustular eruption with fever and leukocytosis developing during pregnancy. Many consider this to be a variant of pustular psoriasis that occurs during pregnancy. If *bed rest*, *emollients*, *compresses*, and *mild topical corticosteroids* are ineffective, *systemic corticosteroids* have been used effectively in the past. More recently, *oral ciclosporin* has proved effective for impetigo herpetiformis. This drug, which has a pregnancy category C rating, is administered in two divided doses totaling 4 to 5 mg/kg daily. Concerns about cumulative toxicity, such as nephrotoxicity, are less worrisome in impetigo herpetiformis because the disorder may resolve at the end of pregnancy, limiting the amount of ciclosporin prescribed. Although there is not as much experience in the use of biologic agents for impetigo herpetiformis, the limited data available for these agents suggests that they are relatively safe during pregnancy. Most are rated as pregnancy category B, meaning that there is no evidence of fetal toxicity in animal studies; however, these drugs can affect the fetal immune system, and postnatal immune infection has occurred.

Specific Investigations

- Skin biopsy (if the clinical diagnosis of psoriasis is uncertain)
- Laboratory investigations

- Serum electrolytes and calcium for patients with pustular psoriasis
- ASO or bacterial cultures for patients with guttate psoriasis
- Appropriate drug-related monitoring for patients on systemic therapies

Investigation is not required in the majority of cases. Skin biopsy may be helpful if the diagnosis is in question, but is usually not needed.

As discussed later, a range of investigations are required for screening and monitoring when using systemic therapies.

Routine screening for tuberculosis has been advised for patients treated with biologic therapies. Because methotrexate and ciclosporin are also immunosuppressive, testing for tuberculosis and, if positive, chest radiography have been suggested before treatment with these agents. Ciclosporin guidelines call for frequent monitoring of blood pressure and chemistry screening, with particular attention to serum creatinine and magnesium. Methotrexate guidelines call for periodic monitoring of complete blood count (CBC) and platelet counts and chemistry screening with liver function tests. Assays for hepatic fibrosis such as the serum aminoterminal propeptide of type III procollagen or liver biopsies are advised in certain patients. Monitoring for viral hepatitis or HIV infection should be considered in populations at risk for those disorders, and many advocate routine hepatitis screening in any patient before biologic therapy, methotrexate, or ciclosporin. Serum cholesterol and triglycerides are particularly important in patients treated with oral acitretin.

From the Medical Board of the National Psoriasis Foundation: monitoring and vaccinations in patients treated with biologics for psoriasis

Lebwohl M, Bagel J, Gelfand JM, Gladman D, Gordon KB, Hsu S, et al. *J Am Acad Dermatol* 2008; 58: 94–105.

Apart from history, physical examination, routine chemistry screening, CBC, and platelet counts, testing for tuberculosis is advised for patients treated with all of the biologics. Liver function tests should be monitored more frequently in patients treated with infliximab; testing for hepatitis B and C is now advocated before starting biologic therapy.

Cyclosporine and psoriasis: 2008 National Psoriasis Foundation Consensus Conference

Rosmarin DM, Lebwohl M, Elewski BE, Gottlieb AB; National Psoriasis Foundation. *J Am Acad Dermatol* 2010; 62: 838–53.

Oral ciclosporin in doses up to 5 mg/kg daily is dramatically effective for psoriasis, but is limited by the development of nephrotoxicity.

This article presents guidelines regarding dosage and monitoring, drug interactions, and complications of ciclosporin.

In patients treated with ciclosporin, blood and platelet counts as well as comprehensive serum chemistries are warranted, including blood urea nitrogen, creatinine, potassium, magnesium, uric acid, liver function tests, and lipids. Two baseline serum creatinine levels and two baseline blood pressure measurements should be obtained before starting ciclosporin therapy. Baseline testing for hepatitis B and C is advocated. Tuberculosis testing should be performed at baseline and annually thereafter.

Methotrexate and psoriasis: 2009. National Psoriasis Foundation Consensus Conference

Kalb R, Strober B, Weinstein G, Lebwohl M. *J Am Acad Dermatol* 2009; 60: 824–37.

Methotrexate in psoriasis: consensus conference

Roenigk HH Jr, Auerbach R, Maibach H, Weinstein G, Lebwohl M. *J Am Acad Dermatol* 1998; 38: 478–85.

Methotrexate remains one of the most effective systemic agents for psoriasis. After an initial test dose of 2.5 to 7.5 mg, weekly doses ranging from 15 to 30 mg can be used to clear psoriasis in most patients. The most worrisome side effects are hepatotoxicity and bone marrow suppression.

These articles review many of the publications on methotrexate and cover laboratory monitoring guidelines, including blood work and liver biopsy, dosage guidelines, drug interactions, and side effects.

Patients treated with methotrexate should have baseline blood and platelet counts as well as liver function tests and creatinine. Many advocate baseline serologic studies for hepatitis B and hepatitis C, and new guidelines require baseline and annual testing for tuberculosis. In Europe, assays for the aminoterminal propeptide of type III procollagen are obtained. In patients without risk factors for

hepatic fibrosis (such as obesity), liver biopsies may not be required or their frequency markedly reduced. Many dermatologists in the United States still obtain periodic liver biopsies to monitor hepatic fibrosis.

First-Line Therapies

• Anthralin (dithranol)	B
• Coal tar	A
• Salicylic acid	C
• Topical corticosteroids	A
• Vitamin D analogs	A
• Tazarotene	A
• Sun exposure	B
• Tacrolimus ointment	A
• Pimecrolimus cream	A

A randomized, double-blind, vehicle-controlled study of a novel liposomal dithranol formulation in psoriasis

Saraswat A, Agarwal R, Katare OP, Kaur I, Kumar B. J Dermatol Treat 2007; 18: 40–5.

Twenty patients were enrolled in a bilateral comparison controlled trial of 0.5% dithranol entrapped in phospholipid liposomes on one side of the body compared with the vehicle (10 patients) or a conventional 1.15% dithranol, 1.15% salicylic acid, and 5.3% coal tar preparation (10 patients) applied daily, using a 30-minute short-contact regimen for 6 weeks. Both active preparations resulted in significant improvement in psoriasis, but there was less perilesional erythema and skin staining on the side treated with the liposome preparation than with the conventional cream.

Anthralin preparations have been used successfully for psoriasis for decades, but staining and irritation have limited their acceptance by both patients and physicians. Attempts to formulate nonstaining, nonirritating versions of anthralin have had limited success.

Efficacy of topical 5% liquor carbonis detergens vs. its emollient base in the treatment of psoriasis

Kanzler MH, Gorsulowsky DC. Br J Dermatol 1993; 129: 310–4.

Liquor carbonis detergens 5% resulted in more improvement in psoriasis than its vehicle emollient base in a bilateral-paired comparison study.

Tars are available in gels, creams, emollient creams, and ointments and are also available in emulsions that are added to the bath. There is a general belief that more cosmetically elegant preparations are better tolerated by patients but less effective. Crude coal tar is quite effective, but quite messy.

The role of salicylic acid in the treatment of psoriasis

Lebwohl M. Int J Dermatol 1999; 38: 16–24.

Salicylic acid is a keratolytic agent that removes scale and allows other topical medications to penetrate. There is a marked increase in penetration of topical corticosteroids when combined with 2% to 10% salicylic acid. Combinations of salicylic acid and tar or anthralin have also been used successfully, but salicylic acid inactivates calcipotriol. Moreover, salicylic acid blocks UVB and should therefore not be applied before phototherapy.

Evaluation of the efficacy and safety of clobetasol propionate spray in the treatment of plaque-type psoriasis

Jarratt MT, Clark SD, Savin RC, Swinyer LJ, Safley CF, Brodell RT, et al. Cutis 2006; 78: 348–54.

The efficacy and tolerability of clobetasol propionate foam 0.05% in the treatment of mild to moderate plaque-type psoriasis of nonscalp regions

Gottlieb AB, Ford RO, Spellman MC. J Cutan Med Surg 2003; 7: 185–92.

Clobetasol propionate shampoo 0.05%: a new option to treat patients with moderate to severe scalp psoriasis

Jarratt M, Breneman D, Gottlieb AB, Poulin Y, Liu Y, Foley V. J Drugs Dermatol 2004; 3: 367–73.

The efficacy of topical corticosteroids for psoriasis has been demonstrated in numerous double-blind, placebo-controlled trials of large numbers of patients. Topical corticosteroids are available in many vehicles, including foams, emollient foams, sprays, shampoos, solutions, lotions, creams, emollient creams, ointments, tapes, and gels.

Superpotent corticosteroids such as clobetasol can be associated with cutaneous and systemic side effects. Clinically significant adrenal suppression is seldom considered, and tests for adrenal function are virtually never performed. Practicing dermatologists are more concerned with the side effects of atrophy, telangiectasia, striae, and tachyphylaxis. For all these reasons, superpotent corticosteroid use should be limited to 2 to 4 weeks and less than 50 g/week. Superpotent corticosteroids should not be occluded and should not be used on the face or intertriginous sites. If at all possible, they should be avoided in children.

An investigator-masked comparison of the efficacy and safety of twice daily applications of calcitriol 3 µg/g ointment vs. calcipotriol 50 µg/g ointment in subjects with mild to moderate chronic plaque-type psoriasis

Zhu X, Wang B, Zhao G, Gu J, Chen Z, Briantais P, et al. J Eur Acad Dermatol Venereol 2007; 21: 466–72.

In this investigator-blinded study, 250 subjects were treated twice daily for 12 weeks with either calcitriol or calcipotriol ointments. Both agents were comparably effective, but there were more local cutaneous adverse events in patients treated with calcipotriol than those treated with calcitriol.

Because local irritation occurs in up to 20% of patients treated with calcipotriol on facial or intertriginous skin, calcitriol may be a better therapeutic option for those sites.

Once daily treatment of psoriasis with tacalcitol compared with twice daily treatment with calcipotriol. A double-blind trial

Veien NK, Bjerke JR, Rossmann-Ringdahl I, Jakobsen HB. Br J Dermatol 1997; 137: 581–6.

Tacalcitol ointment applied once daily proved to be slightly less effective than calcipotriol ointment twice daily in this 8-week, double-blind study conducted in 287 patients.

A 52-week randomized safety study of a calcipotriol/betamethasone dipropionate two-compound product (Dovobet/Daivobet/Taclonex) in the treatment of psoriasis vulgaris

Kragballe K, Austad J, Barnes L, Bibby A, de la Brassinne M, Cambazard F, et al. Br J Dermatol 2006; 154: 1155–60.

Six hundred and thirty-four patients were treated once daily for 4 weeks with a combination ointment containing calcipotriol and betamethasone dipropionate. After 4 weeks they were randomized to receive either the combination product or the combination product alternating with calcipotriol ointment at 4-week intervals or calcipotriol ointment alone as needed for 48 weeks in this double-blind trial. The combination product was consistently more effective than calcipotriol, and patients treated throughout with the combination product had the fewest side effects. Cutaneous atrophy occurred in four (1.9%) of those randomized to receive the combination ointment for 52 weeks.

Calcipotriol is a relatively unstable molecule that is inactivated upon mixing with many other topical agents, so the availability of a stable combination ointment of calcipotriol with a corticosteroid is desirable. Long-term therapy with any product containing a topical corticosteroid should be done with caution to avoid cutaneous atrophy and especially the development of striae. To minimize local cutaneous side effects, avoid strong corticosteroids on the face and intertriginous sites. Use intermittent dosing such as weekend therapy for maintenance of therapeutic effect.

Tazarotene cream in the treatment of psoriasis: two multicenter, double-blind, randomized, vehicle-controlled studies of the safety and efficacy of tazarotene creams 0.05% and 0.1% applied once daily for 12 weeks

Weinstein GD, Koo JY, Krueger GG, Lebwohl M, Love NJ, Menter MA, et al; Tazarotene Cream Clinical Study Group. J Am Acad

Dermatol 2003; 48: 760–7.

Tazarotene creams 0.1% and 0.05% were compared with vehicle once daily for 12 weeks in this double-blind study. Tazarotene 0.1% was more effective, but also more irritating, than the 0.05% cream, and both were superior in efficacy to vehicle.

Tazarotene creams are slightly less effective, but also less irritating, than tazarotene 0.1% and 0.05% gels.

Tacrolimus ointment is effective for facial and intertriginous psoriasis

Lebwohl M, Freeman AK, Chapman MS, Feldman SR, Hartle JE, Henning A; Tacrolimus Ointment Study Group. J Am Acad Dermatol 2004; 51: 723–30.

One hundred and sixty-seven patients were treated in this double-blind, placebo-controlled trial of tacrolimus 0.1% ointment applied twice daily for 8 weeks for facial and intertriginous psoriasis. At the end of 8 weeks 65.2% of tacrolimus ointment-treated patients and 31.5% of vehicle-treated patients were clear or almost clear.

Pimecrolimus cream 1% in the treatment of intertriginous psoriasis: a double-blind, randomized study

Gribetz C, Ling M, Lebwohl M, Pariser D, Draelos Z, Gottlieb AB, et al. J Am Acad Dermatol 2004; 51: 731–8.

In this double-blind study 57 patients were treated with 1% pimecrolimus cream or placebo. At the end of week 8, 71% of pimecrolimus-treated patients were clear or almost clear, compared with 41% of vehicle-treated patients.

Topical calcineurin inhibitors are valuable alternatives for psoriasis in facial and intertriginous sites, which are particularly susceptible to corticosteroid side effects and easily irritated by calcipotriol or tazarotene.

The percentage of patients achieving PASI 75 after 1 month and remission time after climatotherapy at the Dead Sea

Harari M, Novack L, Barth J, David M, Friger M, Moses SW. Int J Dermatol 2007; 46: 1087–91.

Sixty-four patients were treated with climatotherapy at the Dead Sea, which included bathing in Dead Sea water and gradually increasing sun exposure. All patients achieved PASI 50, and 75.9% achieved PASI 75. The median time to recurrence of a lesion of psoriasis was 23.1 weeks, and the median duration of effect, defined

as the time to 50% relapse in the PASI improvement, was 33.6 weeks.

The Dead Sea is the lowest point on earth and has the highest concentration of minerals of any body of water on the earth. The mineral haze in the atmosphere through which sunlight passes results in a unique spectrum of sunlight that accounts for the exceptional therapeutic responses. Two to four weeks of Dead Sea sun exposure and bathing are required to achieve significant benefit.

Second-Line Therapies

• UVB	A
• Narrowband UVB	A
• PUVA	A
• Acitretin	A
• Apremilast	A
• Adalimumab	A
• Etanercept	A
• Infliximab	A
• Ustekinumab	A
• Secukinumab	A
• Ixekizumab	A
• Methotrexate	A
• Ciclosporin	A

Components of the Goeckerman regimen

Le Vine MJ, White HA, Parrish JA. J Invest Dermatol 1979; 73: 170–3.

The efficacy of UVB phototherapy is improved by the addition of a topical tar preparation or lubricating base; 5% crude coal tar is no more effective than lubricating base when combined with a phototherapy regimen.

The original Goeckerman regimen involved inpatient application of crude coal tar, which was removed before daily UVB phototherapy. Most current phototherapy regimens involve outpatient treatment three times per week with topical application of mineral oil or petrolatum.

Narrowband UV-B produces superior clinical and histopathological resolution of moderate-to-severe psoriasis in patients compared with broadband UV-B

Coven TR, Burack LH, Gilleaudeau R, Keogh M, Ozawa M, Krueger JG. Arch Dermatol 1997; 133: 1514–22.

Twenty-two patients were treated in a bilateral comparison study with narrowband UVB on one side and broadband UVB on the other. The side treated with narrowband UVB cleared more quickly and more completely than the side treated with broadband UVB.

Randomized double-blind trial of the treatment of chronic plaque psoriasis: efficacy of psoralen-UV-A therapy vs. narrowband UV-B therapy

Yones SS, Palmer RA, Garibaldinos TT, Hawk JL. Arch Dermatol 2006; 142: 836–42.

In this double-blind study 93 patients were treated twice weekly with either narrowband UVB or PUVA until clearance or up to a maximum of 30 sessions. In patients with skin types 1 to 4, PUVA was significantly more effective than UVB, with 84% of PUVA-treated patients clearing compared with 65% of narrowband UVB-treated patients. PUVA cleared patients after a median of 17 treatments, compared with 28.5 treatments for narrowband UVB. Six months after the last treatment 68% of patients treated with PUVA remained clear, compared with 35% of patients treated with narrowband UVB.

Although PUVA is more effective than narrowband UVB, it is more difficult to administer and has an increased risk of phototoxicity and carcinogenicity. Baseline and annual eye examinations have been suggested

for patients treated with oral PUVA, but initial concerns about the development of cataracts in these patients have not been borne out over time. Baseline serologies for lupus were once recommended before starting patients on PUVA, but are now only obtained in patients who have other signs or symptoms of the disease.

PUVA therapy for psoriasis: comparison of oral and bath-water delivery of 8-methoxypsoralen

Lowe NJ, Weingarten D, Bourget T, Moy LS. J Am Acad Dermatol 1986; 14: 754–60.

Bath-water delivery of methoxsalen (bath-PUVA) 3.7 mg/L (approximately 60 mg dissolved in a tub of water) is as effective as oral PUVA, but requires less UVA and is not associated with systemic side effects such as nausea. Phototoxicity may be increased.

Side effects of burning, sun sensitivity, and, especially, photocarcinogenicity are of concern. Topically applied methoxsalen has also been shown to be effective for psoriasis, but is associated with more phototoxicity.

Efficacy and safety results from the randomized controlled comparative study of adalimumab vs. methotrexate vs. placebo in patients with psoriasis (CHAMPION)

Saurat JH, Stingl G, Dubertret L, Papp K, Langley RG, Ortonne JP, et al. Br J Dermatol 2008; 158: 558–66.

Adalimumab 40 mg every other week after an 80-mg loading dose was compared with methotrexate 7.5 mg orally, increased according to clinical response up to 25 mg per week or placebo for 16 weeks. Of adalimumab-treated patients, 79.6% achieved PASI 75, compared with 35.5% of those patients treated with methotrexate and 18.9% of those treated with placebo. Methotrexate patients suffered the most adverse events leading to study discontinuation, mostly related to hepatic complications.

This was the first placebo-controlled trial of methotrexate for psoriasis. The trial design has been criticized for starting methotrexate at a low dose. Nevertheless, the clear efficacy of adalimumab and the side effects of methotrexate were demonstrated by this study.

A double-blind, placebo-controlled trial of acitretin for the treatment of psoriasis

Olsen EA, Weed WW, Meyer CJ, Cobo LM. J Am Acad Dermatol

1989; 21: 681–6.

In a double-blind study 15 patients were treated with a daily acitretin dose of 25 or 50 mg or placebo for 8 weeks. All were then treated in an open-label study with either 25 or 75 mg of acitretin daily. Improvement in psoriasis was only moderate.

Acitretin plus UVB therapy for psoriasis. Comparisons with placebo plus UVB and acitretin alone

Lowe NJ, Prystowsky JH, Bourget T, Edelstein J, Nychay S, Armstrong R. J Am Acad Dermatol 1991; 24: 591–4.

Photochemotherapy for severe psoriasis without or in combination with acitretin: a randomized, double-blind comparison study

Tanew A, Guggenbichler A, Hönigsmann H, Geiger JM, Fritsch P. J Am Acad Dermatol 1991; 25: 682–4.

This was a double-blind study of 60 patients treated with either PUVA alone or PUVA in combination with acitretin. Ninety-six percent of patients treated with acitretin and PUVA achieved marked or complete clearing, compared with 80% of patients treated with PUVA alone. The cumulative UVA dose used for the acitretin + PUVA group was 42% lower than for the patients treated with PUVA alone.

Acitretin monotherapy has limited benefit for psoriasis, partly because of its limited efficacy and partly because higher dosing results in more mucocutaneous side effects, such as hair loss and cheilitis. In combination with other treatments such as UVB or PUVA, even low doses of acitretin result in dramatically enhanced efficacy. It is also useful in combination or monotherapy for palm and sole psoriasis.

Methotrexate versus cyclosporine in moderate-to-severe chronic plaque psoriasis

Heydendael VM, Spuls PI, Opmeer BC, de Borgie CA, Reitsma JB, Goldschmidt WF, et al. N Engl J Med 2003; 349: 658–65.

Eighty-eight patients were randomized to treatment with either methotrexate starting at 15 mg and adjusted according to clinical response or ciclosporin starting at 3 mg/kg and adjusted according to clinical response. Psoriasis improved in both groups, with a slightly greater response in the ciclosporin group. Twelve of 44 patients in the methotrexate group had to discontinue treatment because of liver

function test abnormalities.

Apremilast, an oral phosphodiesterase 4 (PDE4) inhibitor, in patients with moderate to severe plaque psoriasis: results of a phase III, randomized, controlled trial (Efficacy and Safety Trial Evaluating the Effects of Apremilast in Psoriasis [ESTEEM] 1)

Papp K, Reich K, Leonardi CL, Kircik L, Chimenti S, Langley RG, et al. J Am Acad Dermatol 2015; 73: 37–49.

Patients were treated with either apremilast 30 mg twice daily or placebo for the first 12 weeks of this study. At week 16, 33.1% of patients achieved PASI 75 compared with 5.3% of placebo-treated patients. *Although these results are modest compared with newer biologic therapies, the advantage of an oral formulation is clear. The safety profile, at least in the short term, appears to be good, with the main adverse events being gastrointestinal symptoms and weight loss.*

Etanercept treatment for children and adolescents with plaque psoriasis

Paller AS, Siegfried EC, Langley RG, Gottlieb AB, Pariser D, Landells I, et al.; Etanercept Pediatric Psoriasis Study Group. N Engl J Med 2008; 358: 241–51.

Two hundred and eleven patients age 4 to 17 years participated in this double-blind trial of weekly injections of placebo or 0.8 mg/kg of etanercept. Fifty-seven percent of etanercept-treated children achieved PASI 75, compared with 11% of those treated with placebo.

In adults etanercept can be administered in doses of 50 mg twice weekly. In the United States, after 3 months the dosage is lowered to 50 mg administered subcutaneously once weekly, but in other countries the twice-weekly dosing can continue. As in adults, the pediatric dose of 0.8 mg/kg is effective in children with psoriasis and psoriatic arthritis.

Adalimumab therapy for moderate to severe psoriasis: a randomized, controlled phase III trial

Menter A, Tying SK, Gordon K, Kimball AB, Leonardi CL, Langley RG, et al. J Am Acad Dermatol 2008; 58: 106–15.

In this 1212-patient, double-blind, placebo-controlled trial of adalimumab 40 mg every other week for 15 weeks, 71% of adalimumab-treated patients achieved PASI 75, compared with 7% of placebo-treated patients.

Even higher response rates were achieved in patients treated with

adalimumab 40 mg subcutaneously every week. A loading dose of 80 mg of adalimumab results in much faster clinical responses.

A randomized comparison of continuous vs. intermittent infliximab maintenance regimens over 1 year in the treatment of moderate-to-severe plaque psoriasis

Menter A, Feldman SR, Weinstein GD, Papp K, Evans R, Guzzo C, et al. J Am Acad Dermatol 2007; 56: 31.e1–15.

In this double-blind study 835 patients with moderate to severe psoriasis were treated with either infliximab 3 mg/kg or 5 mg/kg or placebo at weeks 0, 2, and 6. PASI 75 was achieved by 75.5% of patients in the 5 mg/kg group, compared with 70.3% in the 3 mg/kg group. At week 14, infliximab-treated patients were rerandomized to continuous or intermittent maintenance regimens. Greater improvements in psoriasis occurred with continuous rather than intermittent treatment and with the 5 mg/kg dose.

Continuous infliximab therapy may suppress the development of human antichimeric antibodies, which have been associated with more infusion reactions and reduced responsiveness to the drug.

Efficacy and safety of ustekinumab, a human interleukin-12/23 monoclonal antibody, in patients with psoriasis: 52-week results from a randomised, double-blind, placebo-controlled trial (PHOENIX 2)

Papp KA, Langley RG, Lebwohl M, Krueger GG, Szapary P, Yeilding N, et al. Lancet 2008; 371: 1675–84.

In this double-blind study 1230 patients were treated with ustekinumab 45 mg or 90 mg or placebo. The drug was administered subcutaneously at weeks 0 and 4 and every 12 weeks thereafter. Of those treated with 45 mg, 66.7% achieved PASI 75 compared with 75.7% of those treated with 90 mg and 3.7% of those treated with placebo. At week 28 partial responders (i.e., those who achieved PASI 50 but not PASI 75) were rerandomized to increase dosing to every 8 weeks or to continue every 12 weeks. Of those who increased to 90 mg of ustekinumab every 8 weeks, 68.8% achieved PASI 75 by week 52, compared with only 33.3% of those who continued dosing every 12 weeks.

Ustekinumab is highly effective for psoriasis, and safety data up to 8 years are promising with regard to infection, malignancy, and cardiovascular disease. Because of the duration of its effect, ustekinumab can be

administered as infrequently as every 12 weeks, although many patients need injections every 8 weeks to maintain clearing.

Secukinumab in plaque psoriasis—results of two phase 3 trials

Langley RG, Elewski BE, Lebwohl M, Reich K, Griffiths CE, Papp K, et al. *N Engl J Med* 2014; 371: 326–38.

Subcutaneous secukinumab 300 mg, 150 mg, or placebo was administered once weekly for 5 weeks and then every 4 weeks and compared with placebo or etanercept 50 mg twice weekly in this double-blind study. Up to 81.6% of patients achieved PASI 75 with the 300-mg dose of secukinumab and up to 71.6% with the 150-mg dose, which were superior to etanercept and to placebo.

Secukinumab 300 mg (two 150-mg subcutaneous injections) is the preferred dose and results in rapid and sustained clearing of psoriasis. Significant numbers of patients achieved PASI 90 and even PASI 100. The only side effect clearly linked to the drug was an increase in monilial infections.

Comparison of ixekizumab with etanercept or placebo in moderate-to-severe psoriasis (UNCOVER-2 and UNCOVER-3): results from two phase 3 randomised trials

Griffiths CE, Reich K, Lebwohl M, van de Kerkhof P, Paul C, Menter A, et al. *Lancet* 2015; 386: 541–51.

Subcutaneous 160 mg of ixekizumab followed by 80 mg every 2 weeks or every 4 weeks was compared with etanercept 50 mg every 2 weeks or placebo in this double-blind, double-dummy study. PASI 75 was achieved by up to 89.7% of patients treated with ixekizumab every 2 weeks and up to 77.5% in those treated every 4 weeks. Both regimens were superior to etanercept and to placebo.

After a loading dose of 160 mg (two 80-mg subcutaneous injections), 80 mg of ixekizumab every 2 weeks is the approved dose for up to 12 weeks. Thereafter, 80 mg every 4 weeks is approved for maintenance, although every-2-week maintenance is being studied. Rapid, sustained clearing of psoriasis can be expected, and significant numbers of patients achieve PASI 90 and PASI 100. Monilial infections can occur.

Third-Line Therapies

• Combination therapy	A
• Topical 5-fluorouracil	C
• Indigo naturalis	A
• Sulfasalazine (sulphasalazine)	A
• Mycophenolate mofetil	B
• Hydroxycarbamide (hydroxyurea)	B
• Azathioprine	C
• FK-506	A
• Fumaric acid esters	B
• Antibiotics	C
• Colchicine	C
• Laser (excimer, pulsed dye)	C
• Cryotherapy	C
• Grenz rays	B
• Leflunomide	A
• Golimumab	A
• Certolizumab	A
• Brodalumab	A
• Tofacitinib	A
• Topical Janus kinase inhibitors	A

Combination treatments for psoriasis: a systematic review and meta-analysis

Bailey EE, Ference EH, Alikhan A, Hession MT, Armstrong AW. Arch Dermatol 2012; 148: 511–22.

The side effects of psoriasis treatments can be minimized and efficacy enhanced by combining low doses of different therapies. Rotational therapy refers to a method in which patients cleared with one psoriasis therapy are subsequently treated with different therapies to minimize the cumulative toxicity of any given treatment. Thus the hepatotoxicity of cumulative doses of methotrexate, the nephrotoxicity of ciclosporin, and the carcinogenicity of PUVA can be minimized.

The most commonly used combinations involve retinoids and UVB and retinoids and PUVA. UVB and PUVA have been used in combination with one another as well as with methotrexate. Retinoids are among the safest systemic agents for psoriasis and have been combined with methotrexate and ciclosporin, although liver function tests should be watched carefully when methotrexate and acitretin are used together. The combination of methotrexate and ciclosporin is a dramatically effective therapy, as is the combination of ciclosporin and hydroxycarbamide. Methotrexate has also been used with hydroxycarbamide, but blood counts must be watched very carefully.

Although this conference predated the introduction of biologic therapies for psoriasis, all of the currently approved biologics have been administered with methotrexate, acitretin, ciclosporin, and phototherapy. Because methotrexate and ciclosporin are immunosuppressive, they should be used cautiously with biologics and for as short a period of combination as possible. An exception may be the combination of methotrexate with infliximab, as concomitant methotrexate has been shown to reduce the development of antichimeric antibodies.

Clinical efficacy of a 308 nm excimer laser for treatment of psoriasis vulgaris

He YL, Zhang XY, Dong J, Xu JZ, Wang J. Photodermatol Photoimmunol Photomed 2007; 23: 238–41.

In this open-label study 40 patients were treated twice weekly for up to 15 treatments. PASI scores improved by approximately 90%.

The excimer laser is a useful therapy for localized plaques of psoriasis. Its

main side effect is local cutaneous burning.

Targeted UVB phototherapy for psoriasis: a preliminary study

Lapidoth M, Adatto M, David M. Clin Exp Dermatol 2007; 32: 642–5.

This high-intensity targeted UVB lamp (290–320 nm; Be Clear) resulted in significant improvement in localized plaques without treating normal surrounding skin.

Efficacy of the pulsed dye laser in the treatment of localized recalcitrant plaque psoriasis: a comparative study

Erceg A, Bovenschen HJ, van de Kerkhof PC, Seyger MM. Br J Dermatol 2006; 155: 110–4.

Pulsed dye laser (PDL) was compared with the combination calcipotriol/betamethasone dipropionate ointment in an open-label, bilateral comparison study. Twelve weeks after treatment there was 62% improvement in psoriasis severity scores on the PDL-treated side, compared with 19% reduction on the combination calcipotriol/betamethasone dipropionate side.

Weekly pulse dosing schedule of fluorouracil: a new topical therapy for psoriasis

Pearlman DL, Youngberg B, Engelhard C. J Am Acad Dermatol 1986; 15: 1247–52.

Fourteen patients were treated with topical 5-fluorouracil with occlusion 2 to 3 days per week for a mean of 15.7 weeks. Eleven patients achieved 90% clearing of treated lesions, compared with 6% for placebo.

Because of concern about absorption, topical 5-fluorouracil should only be used on isolated plaques. Irritation is the main side effect.

Clinical assessment of patients with recalcitrant psoriasis in a randomized, observer-blind, vehicle-controlled trial using indigo naturalis

Lin YK, Chang CJ, Chang YC, Wong WR, Chang SC, Pang JH. Arch Dermatol 2008; 144: 1457–64.

Indigo naturalis proved to be an effective topical therapy for psoriasis with clearance or near clearance in 31 of 42 subjects (74%). Staining of skin and clothing is a drawback.

Sulfasalazine improves psoriasis. A double-blind analysis

Gupta AK, Ellis CN, Siegel MT, Duell EA, Griffiths CE, Hamilton TA, et al. Arch Dermatol 1990; 126: 487–93.

Fifty patients participated in this double-blind, placebo-controlled trial. Marked improvement was reported in 41% of the sulfasalazine-treated patients and moderate improvement in another 41%. Over one quarter of the sulfasalazine-treated patients discontinued the study because of side effects of rash or nausea.

Mycophenolate mofetil (CellCept) for psoriasis: a two- center, prospective, open-label clinical trial

Zhou Y, Rosenthal D, Dutz J, Ho V. J Cutan Med Surg 2003; 7: 193–7.

Twenty-three patients were treated in an open-label study of mycophenolate mofetil 2 to 3 g daily for 12 weeks. At the end of 12 weeks PASI scores improved by 47%. Only 22% of patients did not have a significant response. Five patients developed nausea, and one developed transient leukopenia.

Mycophenolate mofetil is highly effective in a subset of psoriasis patients. Gastrointestinal side effects can be limited by administering the drug in four divided daily doses instead of the twice-daily dosing recommended in the package insert. An enteric-coated form is also helpful in reducing nausea.

Hydroxyurea in the management of therapy resistant psoriasis

Layton AM, Sheehan-Dare RA, Goodfield MJ, Cotterill JA. Br J Dermatol 1989; 121: 647–53.

Eighty-five patients with psoriasis were treated with long-term hydroxycarbamide in doses of 0.5 to 1.5 g daily. Remissions occurred in 61%. Reversible bone marrow suppression occurred in 35% of patients. Four patients developed cutaneous side effects.

Azathioprine in psoriasis

Greaves MW, Dawber R. Br Med J 1970; 2: 237–8.

Azathioprine can be effective monotherapy for psoriasis, but its use is limited by bone marrow toxicity.

As with 6-thioguanine and hydroxycarbamide, the therapeutically effective dose of azathioprine is close to doses that are toxic to the bone marrow. With all three of these drugs, frequent blood counts are essential.

Systemic tacrolimus (FK 506) is effective for the treatment of psoriasis in a double-blind, placebo-controlled study

European FK 506 Multicentre Psoriasis Study Group. Arch Dermatol

1996; 132: 419–23.

Fifty patients with psoriasis were treated for 9 weeks in this double-blind, placebo-controlled study. Starting doses were 0.05 mg/kg daily and could be increased up to 0.15 mg/kg daily. Tacrolimus-treated patients had significantly greater improvements in PASI scores than those receiving placebo. Diarrhea, paresthesias, and insomnia were the most commonly reported side effects.

Treatment of psoriasis with fumaric acid esters: results of a prospective multicentre study: German Multicentre Study

Mrowietz U, Christophers E, Altmeyer P. Br J Dermatol 1998; 138: 456–60.

Of 101 patients who started this prospective study, 70 completed 4 months of treatment. There was an 80% reduction in PASI scores. Side effects consisted of lymphocytopenia, gastrointestinal complaints, and flushing.

Although not noted in this study, nephrotoxicity has been a recognized side effect of fumaric acid therapy.

Use of rifampin with penicillin and erythromycin in the treatment of psoriasis. Preliminary report

Rosenberg EW, Noah PW, Zanolli MD, Skinner RB Jr, Bond MJ, Crutcher N. J Am Acad Dermatol 1986; 14: 761–4.

All nine patients with streptococcal-associated psoriasis responded to a 5-day course of rifampin (rifampicin) combined with 10 to 14 days of oral penicillin or erythromycin.

The use of oral antibiotics has been championed by Rosenberg and colleagues. Although supported by sound theories and numerous anecdotes, the use of antibiotics for psoriasis has not been supported by controlled clinical trials. Other infections have been linked to psoriasis flares, and other agents that have been used include oral nystatin and oral fluconazole; even tonsillectomy has been advocated.

Therapeutic trials with oral colchicine in psoriasis

Wahba A, Cohen H. Acta Dermatol Venereol 1980; 60: 515–20.

Twenty-two patients were treated in an open trial of colchicine 0.02 mg/kg daily for 2 to 4 months. Of the nine patients with thin papules and plaques, eight noted marked improvement or clearing, but there was little improvement in patients with thick plaques.

Cryotherapy for psoriasis

Nouri K, Chartier TK, Eaglstein WH, Taylor JR. Arch Dermatol 1997; 133: 1608–9.

Target plaques of psoriasis were treated with cryotherapy, resulting in improvement. Local reactions, including pain and vesiculation, were the only side effects other than discoloration.

As with lasers, cryotherapy is only practical for isolated, localized plaques. Despite the Koebner phenomenon, psoriasis does not commonly occur in frozen plaques, but scarring or discoloration can occur.

Psoriasis of the scalp treated with Grenz rays or topical corticosteroid combined with Grenz rays. A comparative randomized trial

Lindelof B, Johannesson A. Br J Dermatol 1988; 119: 241–4.

Forty patients were treated with either Grenz rays or Grenz rays plus topical corticosteroids for scalp psoriasis. Grenz rays were administered at a dosage of 4 Gy at weekly intervals for six treatments; 84% of the Grenz ray–treated patients and 72% of the Grenz ray plus corticosteroid group healed. The addition of topical corticosteroids offered little benefit.

The association between x-ray therapy and squamous cell carcinomas, particularly in patients subsequently treated with PUVA, has led to less use of this valuable modality.

Efficacy and safety of leflunomide in the treatment of psoriatic arthritis and psoriasis: a multinational, double-blind, randomized, placebo-controlled clinical trial

Kaltwasser JP, Nash P, Gladman D, Rosen CF, Behrens F, Jones P, et al.; Treatment of Psoriatic Arthritis Study Group. Arthritis Rheum 2004; 50: 1939–50.

One hundred and ninety patients with psoriasis and psoriatic arthritis were treated in this double-blind, placebo-controlled trial.

Leflunomide proved to be effective for psoriatic arthritis but only modestly effective for psoriasis.

Golimumab, a human TNF-alpha antibody, administered every 4 weeks as a subcutaneous injection in psoriatic arthritis: clinical efficacy, radiographic, and safety findings through 1 year of the randomized, placebo-controlled, GO-REVEAL study

Kavanaugh A, van der Heijde D, McInnes I, Krueger GG, Gladman D,

Gómez-Reino J, et al. Arthritis Rheum 2012; 64: 2504–17.

Golimumab 50 mg or 100 mg administered subcutaneously every 4 weeks resulted in significant improvement in symptoms of psoriatic arthritis. Prevention of x-ray progression of disease was documented.

Although golimumab is approved for psoriatic arthritis, this TNF antagonist also benefits skin lesions of psoriasis.

Successful treatment of moderate to severe plaque psoriasis with the PEGylated Fab' certolizumab pegol: results of a phase II randomised, placebo-controlled trial with a re-treatment extension

Reich K, Ortonne JP, Gottlieb AB, Terpstra IJ, Coteur G, Tasset C, et al. Br J Dermatol 2012; 167: 180–90.

After a loading dose of certolizumab pegol 400 mg, subjects were treated with subcutaneous injections of 200 mg, 400 mg, or placebo every other week; 75%, 83%, and 7% of subjects achieved PASI 75, respectively.

Although certolizumab is approved for Crohn disease and for rheumatoid arthritis in the United States, this TNF antagonist is highly effective for psoriasis.

Phase 3 studies comparing brodalumab with ustekinumab in psoriasis

Lebwohl M, Strober B, Menter A, Gordon K, Weglowska J, Puig L, et al. N Engl J Med 2015; 373: 1318–28.

Psoriasis patients were treated with brodalumab (210 mg or 140 mg every 2 weeks), ustekinumab (45 mg for patients with a body weight ≤100 kg and 90 mg for patients >100 kg at weeks 0 and 4), or placebo for the first 12 weeks of these double-blind trials. Up to 86% of patients achieved PASI 75 and up to 44% achieved PASI 100 with the 210-mg dose of brodalumab, which was superior in several outcomes to 140-mg brodalumab, ustekinumab, and placebo. *A low frequency of monilial infections occurred in brodalumab-treated subjects in these early trials. In later phases of this study and in other studies there were a small number of suicides, which may not be related to the drug, but which did not occur with other treatments blocking IL-17. As a result brodalumab is being scrutinized more closely.*

Erythrodermic Psoriasis

Erythrodermic psoriasis is characterized by marked erythema and scaling affecting the entire cutaneous surface. All the protective functions of the skin are lost, including protection against infection, temperature control, and prevention of fluid loss. Loss of nutrients through the skin leads to anemia and electrolyte imbalance. The most common precipitating cause of erythrodermic psoriasis is the withdrawal of systemic corticosteroids; this should be avoided in patients with psoriasis. Excessive use of topical superpotent corticosteroids, phototherapy burns, and infections have also been implicated as causes of erythrodermic psoriasis.

Patients may require hospitalization with bed rest, emollients, and application of *mild topical corticosteroids*. Because sepsis and shock are complications of erythrodermic psoriasis, monitoring of temperature, blood pressure, urine output, and weight may be important, depending on the severity of the condition. In males and in females not of childbearing potential, *oral retinoids* are among the safest treatments for erythrodermic psoriasis, but are not as reliably effective as *biologics*, *ciclosporin*, or *methotrexate*. *Acitretin* can be started in doses of 25 mg daily and can be increased to 50 mg or higher. *Ciclosporin* in doses of 4 to 5 mg/kg daily results in rapid improvement. *Oral methotrexate* starting at 15 mg per week and gradually increasing up to 30 mg/week is effective within a few weeks. Once erythema has cleared with topical or systemic agents, patients can occasionally be switched to phototherapy or PUVA or to other long-term therapies, including the biologics. Many of the available biologic agents, including *infliximab*, *adalimumab*, *etanercept*, *ustekinumab*, and *ixekizumab*, have been used to treat erythrodermic psoriasis. When these agents either do not work or cannot be used, many of the third-line therapies listed for psoriasis are effective. For example, there are anecdotal reports of *mycophenolate mofetil*, *azathioprine*, and *hydroxycarbamide* working for erythrodermic psoriasis. Combination therapy such as the *combination of methotrexate and ciclosporin* in low doses, or the combination of *methotrexate and infliximab*, can also be effective. There are also anecdotal reports of *carbamazepine* clearing erythrodermic psoriasis.

First-Line Therapies

• Emollients	D
• Topical corticosteroids	D

Second-Line Therapies

• Retinoids	B
• Ciclosporin	B
• Infliximab	D
• Etanercept	D
• Adalimumab	D
• Ustekinumab	D
• Anti-IL-17 antibodies	D
• Methotrexate	B

Third-Line Therapies

• Combination therapy	D
• Mycophenolate mofetil	E
• Hydroxycarbamide (hydroxyurea)	E
• Azathioprine	E
• Carbamazepine	E

Use of short-course class 1 topical glucocorticoid under occlusion for the rapid control of erythrodermic psoriasis

Arbiser JL, Grossman K, Kaye E, Arndt KA. Arch Dermatol 1994; 130: 704–6.

Erythrodermic psoriasis will respond rapidly to oral corticosteroids or to superpotent corticosteroids with occlusion, but withdrawal of these agents often results in a more severe flare. Consequently, these treatments are avoided in patients with erythrodermic psoriasis.

Management of erythrodermic psoriasis with low-dose cyclosporine

Studio Italiano Muticentrico nella Psoriasi (SIMPSO). Dermatology 1993; 187: 30–7.

Thirty-three patients with erythrodermic psoriasis were treated with ciclosporin, starting with up to 5 mg/kg daily; 67% achieved complete remission in a median of 2 to 4 months, and another 27% noted substantial improvement.

Treatment of erythrodermic psoriasis with etanercept

Esposito M, Mazzotta A, de Felice C, Papoutsaki M, Chimenti S. Br J Dermatol 2006; 155: 156–9.

Ten patients were treated with open-label etanercept 25 mg subcutaneously twice weekly. By week 12, 50% had achieved at least 75% improvement in psoriasis severity scores, and that number increased by week 24.

Erythrodermic psoriasis can be a life-threatening condition requiring more rapid-acting agents than etanercept. The latter biologic can be useful in more

chronic and stable forms of the disease.

Efficacy and safety of biologics in erythrodermic psoriasis: a multicentre, retrospective study

Viguier M, Pagès C, Aubin F, Delaporte E, Descamps V, Lok C, et al. Br J Dermatol 2012; 167: 417–23.

Twenty eight patients with 42 flares of erythrodermic psoriasis were treated with infliximab ($n = 24$), adalimumab ($n = 7$), etanercept ($n = 6$), ustekinumab ($n = 3$), or efalizumab ($n = 2$).

The authors point out that short-term control is good with these agents but because of a lack of efficacy or side effects, only one third of patients are on the same biologic at the end of a year.

Efficacy and safety of open-label ixekizumab treatment in Japanese patients with moderate-to-severe plaque psoriasis, erythrodermic psoriasis and generalized pustular psoriasis

Saeki H, Nakagawa H, Ishii T, Morisaki Y, Aoki T, Berclaz PY, et al. J Eur Acad Dermatol Venereol 2015; 29: 1148–55.

This study included eight patients with erythrodermic psoriasis and five with generalized pustular psoriasis. All erythrodermic psoriasis patients and four of five pustular psoriasis patients improved. *It is likely that secukinumab and brodalumab, which work by similar mechanisms, will be effective for erythrodermic psoriasis as well.*

Treatment of pustulous and erythrodermic psoriasis with PUVA therapy and methotrexate

Lekovic B, Dostanic I, Konstantinovic K, Kneitner I. Hautarzt 1982; 33: 284–5.

The combination of PUVA and methotrexate successfully treated five patients with erythrodermic psoriasis and two with pustular psoriasis. According to the authors, annual methotrexate doses could be reduced by 50% by adding PUVA to the regimen.

It is difficult to distinguish a PUVA burn from erythrodermic psoriasis. Nevertheless, some patients with erythrodermic psoriasis are successfully controlled with PUVA. Monotherapy with methotrexate is used more typically.

The treatment of psoriasis with etretinate and acitretin: a follow-up of actual use

Magis NL, Blummel JJ, Kerkhof PC, Gerritsen RM. Eur J Dermatol

2000; 10: 517–21.

In a retrospective review of 94 patients treated with retinoids, there were no serious side effects after 10 years of follow-up. The efficacy of retinoids for pustular and erythrodermic psoriasis was stressed.

Accidental success with carbamazepine for psoriatic erythroderma

Smith KJ, Skelton HG. N Engl J Med 1996; 335: 1999–2000.

A patient with HIV infection and erythrodermic psoriasis was inadvertently treated with carbamazepine instead of etretinate. The patient's erythroderma cleared.

Carbamazepine in doses of 200 to 400 mg daily has been reported to clear erythrodermic psoriasis in some, but not all, patients. Further controlled clinical studies are warranted.

Pustular Psoriasis

Management of pustular psoriasis begins with the *removal of precipitating causes*. Lithium, antimalarials, diltiazem, propranolol, and irritating topical therapy with tar have all been implicated, but the most common cause is the withdrawal of systemic corticosteroids. As in erythrodermic psoriasis, all the protective functions of skin are compromised, and patients are susceptible to infection, fluid loss, electrolyte imbalance, loss of nutrients through the skin, and loss of temperature control. Supportive care and treatment of infection are mandatory. *Oral acitretin* results in rapid improvement. In women of childbearing potential *isotretinoin* may be preferred because the period of teratogenicity of this drug is shorter than that of acitretin. *Cyclosporin*, *infliximab*, *adalimumab*, and *methotrexate* are also highly effective for this life-threatening condition. TNF blockers have been used to treat pustular psoriasis, but caution should be exercised as there have been rare cases of pustular psoriasis caused by their use. *Hydroxycarbamide (hydroxyurea)*, *6-thioguanine*, *mycophenolate mofetil*, *azathioprine*, *dapsone*, and *colchicine* have also been used in isolated patients.

First-Line Therapies

• Topical corticosteroids	E
• Retinoids	B
• Ciclosporin	E
• Infliximab	E
• Adalimumab	E
• Ustekinumab	E
• Ixekizumab and other anti-IL-17 antibodies (see reference under erythrodermic psoriasis)	D
• Methotrexate	B

Second-Line Therapies

• Topical calcipotriol	E
• Etanercept	E
• 6-Thioguanine	E
• Hydroxycarbamide (hydroxyurea)	E
• Mycophenolate mofetil	E
• Azathioprine	E

Isotretinoin vs. etretinate therapy in generalized pustular and chronic psoriasis

Moy RL, Kingston TP, Lowe NJ. Arch Dermatol 1985; 121: 1297–301.

Although isotretinoin was less effective than etretinate for plaque psoriasis, 10 of 11 patients with pustular psoriasis responded.

Many consider acitretin or isotretinoin to be the treatment of choice for patients with pustular psoriasis. Apart from the shorter period of teratogenicity of isotretinoin, it also causes less hair loss than acitretin.

Generalized pustular psoriasis (von Zumbusch) responding to cyclosporine A

Meinardi MM, Westerhof W, Bos JD. Br J Dermatol 1987; 116: 269–70.

This is one of numerous case reports documenting the dramatic response of pustular psoriasis to ciclosporin.

Ciclosporin in doses of 4 to 5 mg/kg daily is usually effective in the treatment of pustular psoriasis.

Infliximab in recalcitrant generalized pustular arthropatic psoriasis

Vieira Serrão V, Martins A, Lopes MJ. Eur J Dermatol 2008; 18: 71–3.

This is a case report of a patient with psoriatic arthritis and acute generalized pustular psoriasis refractory to acitretin, methotrexate, and corticosteroids that responded rapidly to treatment with infliximab, with complete clearing of lesions by week 12, along with improvement in psoriatic arthritis.

Pustular psoriasis induced by infliximab

Thurber M, Feasel A, Stroehlein J, Hymes SR. J Drugs Dermatol 2004; 3: 439–40.

Despite several reports describing the efficacy of infliximab in pustular psoriasis, there are a small number of reports of pustular psoriasis developing in patients treated with infliximab for other indications.

Several reports of psoriasis, and specifically pustular psoriasis, developing after treatment with TNF- α blockers have emerged. Nevertheless, these agents can be highly useful for the treatment of pustular psoriasis.

Long-term efficacy of adalimumab in generalized pustular psoriasis

Zangrilli A, Papoutsaki M, Talamonti M, Chimenti S. J Dermatol Treat 2008; 19: 185–7.

Adalimumab 40 mg subcutaneously once weekly resulted in rapid remission of chronic pustular psoriasis. The remission persisted throughout 72 weeks of treatment.

Ustekinumab: effective in a patient with severe recalcitrant generalized pustular psoriasis

Daudén E, Santiago-et-Sánchez-Mateos D, Sotomayor-López E, García-Díez A. Br J Dermatol 2010; 163: 1346–7.

There have been paradoxical cases of pustular psoriasis induced by ustekinumab.

Etanercept at different dosages in the treatment of generalized pustular psoriasis: a case series

Esposito M, Mazzotta A, Casciello C, Chimenti S. Dermatology 2008; 216: 355–60.

Six patients with generalized pustular psoriasis who failed to respond to conventional treatments were treated with etanercept 25 to 50 mg twice weekly for 48 weeks, with good efficacy.

Because etanercept can be slower acting than other systemic or biologic agents, and because generalized pustular psoriasis can be life threatening, a more rapid-acting agent should be considered for severe disease.

Generalised pustular psoriasis: response to topical calcipotriol

Berth-Jones J, Bourke J, Bailey K, Graham-Brown RA, Hutchinson PE. Br Med J 1992; 305: 868–9.

Three cases of pustular psoriasis responded to topical application of calcipotriol, and the treatment was well tolerated.

It is important to monitor serum calcium when using calcipotriol in this way. Although irritation was not a problem in the reported cases, some care is required in case this develops.

Systemic corticosteroids and folic acid antagonists in the treatment of generalized pustular psoriasis. Evaluation and prognosis based on the study of 104 cases

Ryan TJ, Baker H. Br J Dermatol 1969; 81: 134–45.

Despite the short-term benefit of systemic corticosteroids for pustular psoriasis, once the dose is reduced, rebound flares occur. In this study a significant proportion of patients treated with systemic corticosteroids died.

Methotrexate remains a highly effective modality for the treatment of pustular psoriasis. Doses beginning at 15 mg per week (after an initial test dose) are used.

Third-Line Therapy

• Colchicine

E

Colchicine in generalized pustular psoriasis: clinical response and antibody-dependent cytotoxicity by monocytes and neutrophils

Zachariae H, Kragballe K, Herlin T. Arch Dermatol Res 1982; 274: 327–33.

Three of four patients with pustular psoriasis cleared within 2 weeks of starting oral colchicine.

Colchicine 0.6 mg twice daily can be effective for pustular psoriasis. The dose can be increased by one pill daily, but side effects of diarrhea frequently intervene.

Psychogenic excoriation

Michael E. Abrouk, Jillian W. Wong Millsop, and John Y.M. Koo

Psychogenic excoriation is a psychodermatologic condition in which patients participate in destructive scratching and picking of normal skin or skin with minor surface irregularities. Such behaviors may cause self-inflicted ulcers, abscesses, or scars that can ultimately

become disfiguring. Although traditionally called *neurotic excoriation*, the authors prefer the term *psychogenic excoriation* because the underlying psychopathology may not be neurosis and may range from depression to obsessive-compulsive disease to even psychosis. The traditional term *neurotic excoriation* does our specialty a disservice, making dermatologists feel as if we know what is going on with the patient psychologically when the reality is that there is no way we can know what the underlying psychopathology is without carefully interviewing the patient regarding his or her mental status. Therefore the authors recommend the following approach:

First, do not be fooled by the term *neurotic excoriation*; go beyond the skin to clearly ascertain the nature of the underlying psychopathology. Patient behavior may be associated with underlying depression, anxiety, obsessive-compulsive disorder, psychosis, or borderline personality disorder. Psychogenic excoriations may also be precipitated by emotional stress.

Second, before diagnosing a patient with psychogenic excoriation, it is important to rule out other psychodermatologic disorders, such as dermatitis artefacta (often associated with damage done with sharp objects rather than just fingernails, characteristic secrecy about the etiology of lesions, and often associated with demanding and manipulative personality), or delusions of parasitosis (associated with delusional ideation, particularly the strongly held belief of organisms infesting the skin).

Finally, the appropriate treatment strategy can be determined based on the nature of the underlying psychopathology.

Management Strategy

Because psychogenic excoriation is primarily a psychiatric disorder, for a dermatologist without time or training for psychotherapy, psychopharmacology could be the most feasible line of therapy.

If depression or anxiety is the underlying psychopathology, antidepressants and anti-anxiety agents are considered first-line treatment. One of the author's (J.K.) preferred medications is the tricyclic antidepressant *doxepin*. There is an insufficient number of clinical trials demonstrating its efficacy in this condition, but doxepin is often useful due to its combined antidepressant and antihistaminic/antipruritic activity, which may be critical in disrupting the itch-scratch cycle. Doxepin is usually started at 10 to

25 mg at bedtime, with a gradual increase in dose of 10 to 25 mg every 2 to 4 weeks until the patient is taking up to 100 mg every evening, which is the typical effective antidepressant dose, particularly if the underlying psychopathology is major depression. If the patient requires even higher dosages, a maximum of up to 300 mg daily may be used, provided there are no side effects. Because doxepin can prolong the QT interval, a screening electrocardiogram (ECG) is recommended for patients over age 55 or any patient with a past history of cardiac dysrhythmia. Sedation, syncope, seizures, weight gain, and orthostatic hypotension are other potential side effects.

Selective serotonin reuptake inhibitors (SSRIs) also have been shown in several reports to be effective in patients with psychogenic excoriation. These antidepressant drugs have better safety profiles than doxepin, as they are less associated with sedation and cardiac conduction abnormalities. Other *tricyclic* antidepressants, such as *clomipramine* and *amitriptyline*, and various *benzodiazepines* are third-line therapies that should only be considered if the patient does not respond to more conventional treatments or cannot tolerate the side effects.

For treatment of underlying psychosis, antipsychotics can be effective. *Pimozide*, a traditional antipsychotic; *olanzapine*, an atypical antipsychotic; *aripiprazole*, a second-generation antipsychotic; and *naltrexone*, an opioid antagonist, may have a role for these patients with psychogenic excoriation.

As for borderline personality as the underlying psychopathology, *psychotherapy* is recommended. *Psychotherapy* and *cognitive behavioral techniques*, including aversion therapy and habit reversal treatments, have been reported in certain cases to be effective for this disorder and can be used as adjunctive therapy for other underlying psychopathologies, including those discussed earlier. There are two case reports of the efficacy of *cognitive psychotherapy with laser irradiation* of disfiguring skin lesions, as well as a case report on the efficacy of *hypnosis* to alleviate psychogenic excoriation.

Other strategies for treatment may further enhance systemic pharmacologic treatments and psychotherapy. Treating associated infection and pruritus through the prudent use of *antibiotics* and *antihistamines (oral or topical)*, respectively, and using *topical corticosteroids* may provide additional symptomatic benefit for patients with psychogenic excoriation. Last, a recent study

demonstrated *narrowband ultraviolet (NB-UVB) phototherapy* may be helpful for psychogenic excoriation.

Specific Investigation

- Close follow-up with a primary care physician or psychiatrist is recommended because of the high incidence of comorbid psychiatric conditions

Psychogenic excoriation. Clinical features, proposed diagnostic criteria, epidemiology and approaches to treatment

Arnold LM, Auchenbach MB, McElroy SL. CNS Drugs 2001; 15: 351–9.

A review article that outlines the clinical features of psychogenic excoriation, comorbid psychiatric conditions, therapies, and potential criteria for diagnosis.

Characteristics of 34 adults with psychogenic excoriation

Arnold LM, McElroy SL, Mutasim DF, Dwight MM, Lamerson CL, Morris EM. J Clin Psychiatry 1998; 59: 509–15.

Patients with psychogenic excoriations have a high prevalence of concurrent psychiatric illnesses such as mood disorders (68%), anxiety disorders (41%), somatoform disorders (21%), substance abuse (12%), and eating disorders (12%).

Neurotic excoriations and dermatitis artefacta

Koblenzer CS. Dermatol Clin 1996; 14: 447–55.

A good review article.

The psychiatric profile of patients with psychogenic excoriations

Mutasim DF, Adams BB. J Am Acad Dermatol 2009; 61: 611–3.

In a study of 50 patients with psychogenic excoriations compared with controls, the most significantly associated psychiatric comorbidities are depression and bipolar disorder.

Dermatology and conditions related to obsessive–compulsive disorder

Stein DJ, Hollander E. J Am Acad Dermatol 1992; 26: 237–42.

Patients with psychogenic excoriations often have obsessive-

compulsive symptoms and may therefore respond to specific therapies aimed at this type of disorder.

Neurotic excoriations: a diagnosis of exclusion

Anetakis Poulos G, Algothani L, Bendo S, Zirwas MJ. J Clin Aesthet Dermatol 2012; 5: 63–4.

A 53-year-old woman with a history of schizophrenia, depression, hepatitis C, and diabetes was clinically misdiagnosed with neurotic excoriations instead of her true diagnosis: bullous pemphigoid.

It is essential that the diagnosis of psychogenic excoriations be made when other dermatologic diagnoses are definitively ruled out.

Psychogenic excoriation in a systemic lupus erythematosus patient

Silva BS, Bonin CC, Carvalho JF. Acta Rheumatol Port 2010; 35: 396.

A 37-year-old woman with systemic lupus erythematosus was referred to dermatology due to persistence of lesions refractory to therapy. She was diagnosed with psychogenic excoriation and started on sertraline with complete healing of her dermatologic disease.

The reconstructive challenges and approach to patients with excoriation disorder

Galdyn IA, Chidester J, Martin MC. J Craniofac Surg 2015; 26: 824–5.

Treating patients with psychogenic excoriation requires a multidisciplinary approach. Before any surgical repair or treatment can be rendered, the patient must be stabilized from a psychiatric standpoint.

First-Line Therapy

• Doxepin	E
-----------	---

Psychopharmacology for dermatologic patients

Koo J, Gambla C. *Dermatol Clin* 1996; 14: 509–24.

Describes in further detail the use of doxepin in psychogenic excoriations.

Improvement of chronic neurotic excoriations with oral doxepin therapy

Harris BA, Sherertz EF, Flowers FP. *Int J Dermatol* 1987; 26: 541–3.

Case report of two patients who responded to doxepin 30 mg and 75 mg daily.

Second-Line Therapies

• Sertraline	B
• Paroxetine	E

Sertraline in the treatment of neurotic excoriations and related disorders

Kalivas J, Kalivas L, Gilman D, Hayden CT. *Arch Dermatol* 1996; 132: 589–90.

Sertraline was started at 25 to 50 mg daily and titrated upward to 100 to 200 mg daily as necessary, with improvements seen in 19 of 28 patients (68%) at an average of 4 weeks.

Paroxetine in a case of psychogenic pruritus and neurotic excoriations

Biondi M, Arcangeli T, Petrucci RM. *Psychother Psychosom* 2000; 69: 165–6.

This is one case report demonstrating success with the SSRI paroxetine, which was thought to work secondary to its anticomulsive activity.

Third-Line Therapies

• Fluoxetine	A
• Fluvoxamine	C
• Venlafaxine	E
• Escitalopram	D
• Clomipramine	E
• Amitriptyline	E
• Benzodiazepines	E
• Pimozide	E
• Olanzapine	D
• Aripiprazole	E
• Naltrexone	E
• Psychotherapy	D
• Cognitive behavioral therapy	E
• Hypnosis	E
• Narrowband ultraviolet light	C

A double-blind trial of fluoxetine in pathologic skin picking

Simeon D, Stein DJ, Gross S, Islam N, Schmeidler J, Hollander E. *J Clin Psychiatry* 1997; 58: 341–7.

Fluoxetine was started at 20 mg daily and increased by 20 mg/week up to a maximum of 80 mg daily. Improvements in the treatment arm were statistically significant (based on an intent-to-treat analysis) at 6 weeks, with an average dose of 55 mg daily.

This trial is limited by a small sample (10 patients in the study arm and 11 in the placebo arm), a high dropout rate (40% in the fluoxetine group), and a study period of only 10 weeks, but the study substantiated earlier case reports.

An open clinical trial of fluvoxamine treatment of psychogenic excoriation

Arnold LM, Mutasim DF, Dwight MM, Lamerson CL, Morris EM, McElroy SL. *J Clin Psychopharmacol* 1999; 19: 15–8.

Fluvoxamine was started at 25 to 50 mg daily and increased by up to 50 mg/week to a maximum of 300 mg daily for 12 weeks. Although all 14 participants demonstrated significant improvement in six of eight self-reported scales, the 7 subjects who completed the study (50%) had improvement in only two of eight self-reported scales.

Use of escitalopram in psychogenic excoriation

Pukadan D, Antony J, Mohandas E, Cyriac M, Smith G, Elias A. *Aust NZ J Psychiatry* 2008; 42: 435–6.

Escitalopram was administered at 10 mg/day to two patients: a 63-year-old woman with a 1-month history of diffuse pruritus and excessive excoriation, as well as major depressive disorder; and a 24-year-old man with a 10-year history of repeated nail biting and features of major depressive disorder. In both patients, scratching abated within 2 weeks.

Neurotic excoriations: a review and some new perspectives

Gupta MA, Gupta AK, Haberman HF. *Compr Psychiatry* 1986; 27: 381–6.

A case report of successful treatment using clomipramine 50 mg every evening for 6 months.

Neurotic excoriations: a personality evaluation

Fisher BK, Pearce KI. *Cutis* 1974; 14: 251–4.

Successful treatment with amitriptyline 50 to 75 mg daily was reported.

Neurotic excoriations

Fisher BK. *Can Med Assoc J* 1971; 105: 937–9.

This is a case report of the success of benzodiazepines before the availability of SSRIs. In general, benzodiazepines may be useful only if anxiety is the primary cause of psychogenic excoriations.

Clinical experience with pimozide: emphasis on its use in postherpetic neuralgia

Duke EE. *J Am Acad Dermatol* 1983; 8: 845–50.

This case report primarily demonstrates the efficacy of pimozide (2 mg two or three times daily) in the treatment of postherpetic neuralgia (eight patients) and psychogenic excoriations (two patients).

Efficacy of olanzapine in the treatment of psychogenic excoriation

Blanch J, Grimalt F, Massana G, Navarro V. *Br J Dermatol* 2004; 151: 714–6.

This article describes a series of six patients with psychogenic excoriation who improved dramatically after treatment with olanzapine 2.5 to 10 mg daily.

The treatment of psychogenic excoriation and obsessive compulsive disorder using aripiprazole and fluoxetine

Curtis AR, Richards RW. *Ann Clin Psychiatry* 2007; 19: 199–200.

This is a case report on the success of aripiprazole, a second-generation antipsychotic, and fluoxetine in an 18-year-old woman with psychogenic excoriations and obsessive–compulsive disorder.

Aripiprazole augmentation of venlafaxine in the treatment of psychogenic excoriation

Carter WG, 3rd, Shillcutt SD. *J Clin Psychiatry* 2006; 67: 1311.

This case report discusses the success of aripiprazole and venlafaxine in a 50-year-old woman with psychogenic excoriation, major depressive disorder, and generalized anxiety disorder who had been unresponsive to a serotonin–norepinephrine reuptake inhibitor alone.

Naltrexone for neurotic excoriations

Smith KC, Pittelkow MR. J Am Acad Dermatol 1989; 20: 860–1.

This article discusses the reported efficacy of naltrexone for psychogenic excoriations.

Psychotherapeutic strategy and neurotic excoriations

Fruensgaard K. Int J Dermatol 1991; 30: 198–203.

This article reports a positive impact of goal-directed psychotherapy in 22 patients followed over a period of approximately 5 years for psychogenic excoriations.

Treatment of facial scarring and ulceration resulting from acne excoriée with 585-nm pulsed dye laser irradiation and cognitive psychotherapy

Bowes LE, Alster TS. Dermatol Surg 2004; 30: 934–8.

Two case reports of successful treatment of acne excoriée with a pulsed dye laser to improve the appearance of scars and ulcers, as well as cognitive psychotherapy to maintain improvement.

Acne excoriée: a case report of treatment using habit reversal

Kent A, Drummond LM. Clin Exp Dermatol 1989; 14: 163–4.

This is a case report on the success of habit reversal, a cognitive behavioral technique, for psychogenic excoriations.

The behavioral treatment of neurodermatitis through habit reversal

Rosenbaum MS, Ayllon J. Behav Res Ther 1981; 19: 313–8.

This article reports a response to habit reversal therapy for neurodermatitis in three patients.

Treatment of neurodermatitis by behavior therapy: a case study

Ratcliffe R, Stein N. Behav Res Ther 1968; 6: 397–9.

This is a case report in which neurodermatitis secondary to psychogenic excoriation improved after aversion therapy, a cognitive behavioral technique.

Using hypnosis to facilitate resolution of psychogenic excoriations in acne excoriée

Shenefelt PD. Am J Clin Hypn 2004; 46: 239–45.

In this case report, the acne excoriée in a pregnant woman was successfully alleviated through hypnotic suggestion.

Narrow-band ultraviolet B as a potential alternative treatment for resistant psychogenic excoriation: an open-label study

Ozden MG, Aydin F, Senturk N, Bek Y, Canturk T, Turanli A.
Photodermatol Photoimmunol Photomed 2010; 26: 162–4.

A prospective study assessing the effectiveness of phototherapy for psychogenic excoriation. Of the seven patients who completed the study and received NB-UVB, 50% or more reduction in clinical improvement scale scores was found in 71.4% (five of seven) of patients. The only side effects were xerosis and moderate erythema.

Pyoderma gangrenosum

John Berth-Jones

Pyoderma gangrenosum (PG) is a clinically diagnosed entity presenting as pustules that enlarge, forming ulcers with a dark, necrotic, and undermined margin. Any skin site may be affected. Although PG is usually self-limiting, there is a danger of disfiguring scarring.

Management Strategy

No treatment is always effective. The most consistent results are reported with *systemic corticosteroids* and *ciclosporin*, and these effective but potentially toxic modalities can be employed when the severity of the disease justifies the risks (e.g., when there is facial involvement, extensive disease, or rapid progression). *Infliximab* has been shown to be beneficial in a controlled trial. The evidence regarding other modalities is less conclusive. PG tends to resolve spontaneously, so some of the reports of therapeutic success may simply be the result of the disease following its natural course.

In cases where scarring is not a major concern, consideration should be given to conservative treatment with *wound dressing* only, as most lesions resolve spontaneously. The relatively safe first-line treatments can be tried first. A wide variety of other treatments have been reported to be effective at a more anecdotal level, some are potentially hazardous, some are not universally available, and some are costly, and these third-line modalities can be considered when others are ineffective.

PG may demonstrate the Koebner phenomenon; care should be taken to avoid trauma to the skin. When surgery is unavoidable in patients with a history of PG, the surgeon should be made aware of this risk. Surgical incisions should be kept as short as possible. Careful wound closure may be helpful. *Prophylactic systemic corticosteroids* or *ciclosporin* may be indicated perioperatively.

Effective management of associated systemic diseases such as ulcerative colitis often seems to result in improvement of the PG.

Specific Investigations

- Hematology
- Plasma protein electrophoresis
- Rheumatoid factor
- Antineutrophil cytoplasmic antibodies (ANCA) in selected patients where clinically indicated
- Gastrointestinal workup for inflammatory bowel disease

The many recognized associations with PG include rheumatoid disease, inflammatory bowel disease, myeloproliferative disease such as acute myeloblastic leukemia, plasma cell dyscrasias, and Wegener

granulomatosis. These may warrant investigation and may also influence the choice of treatment.

First-Line Therapies

• Topical tacrolimus	C
• Topical corticosteroids	C
• Dapsone	D
• Intralesional corticosteroids	D
• Minocycline	D
• Nicotine	D
• Topical pimecrolimus	E
• Sodium cromoglycate	D
• Sulfasalazine	D

Topical tacrolimus for pyoderma gangrenosum

Reich K, Vente C, Neumann C. Br J Dermatol 1998; 139: 755–7.

Tacrolimus ointment 0.1% proved effective when used in combination with systemic ciclosporin and also when used alone.

Topical tacrolimus in the management of peristomal pyoderma gangrenosum

Lyon CC, Stapleton M, Smith AJ, Mendelsohn S, Beck MH, Griffiths CEM. J Dermatol Treat 2001; 12: 13–7.

Seven out of 11 cases of peristomal PG healed completely after 2 to 10 weeks of applying tacrolimus 0.3% in carmellose sodium paste (Orabase). Serum levels of tacrolimus were undetectable in all cases. In this open study the results were at least as good as those from clobetasol propionate.

Caution: A case of systemic absorption and acute nephrotoxicity has been reported in a patient who applied 60 mg of tacrolimus ointment (i.e., presumably 60 g of 0.1% ointment) daily to PG.

Pyoderma gangrenosum of the scalp

Peachey RDG. Br J Dermatol 1974; 90: 106.

A case showed slow but steady improvement on 0.1% betamethasone valerate lotion applied under polythene occlusion at night.

Beclomethasone inhaler used to treat pyoderma gangrenosum

Chriba M, Skellett AM, Levell NJ. Clin Exp Dermatol 2010; 35: 337–8.

A case of peristomal PG healed over 4 weeks using beclomethasone dipropionate 200 µg, four puffs daily.

The accepted efficacy of systemic corticosteroids would suggest that topical application might also be beneficial. However, there are only anecdotal reports, often in conjunction with other treatments, to support their efficacy. Potent compounds are generally used, applied once daily, under an occlusive dressing.

Sulfapyridine and sulphone-type drugs in dermatology

Lorincz AL, Pearson RW. Arch Dermatol 1962; 85: 42–56.

Dapsone was successfully employed in the treatment of PG at doses of up to 400 mg daily.

Low cost and familiarity of dermatologists with this drug probably contribute to its popularity. Dapsone has often been used in combination with other modalities, especially systemic corticosteroids. There are also many published cases in which this drug has proved ineffective. Dapsone has been successfully used in children with PG. The mechanism of action is believed to be inhibition of neutrophil migration and the myeloperoxidase system. Crushed dapsone applied topically is reported as effective in a case of peristomal PG.

Triamcinolone and pyoderma gangrenosum

Gardner LW, Acker DW. Arch Dermatol 1972; 106: 599–600.

A case of multifocal PG responded to intralesional triamcinolone acetonide 10 mg/mL. Doses ranging from 40 mg to 200 mg were injected at any one time.

Intralesional or perilesional injection of corticosteroids appears to be very helpful in some cases. The corticosteroid is usually injected into the skin around the active margins of lesions.

The successful use of minocycline in pyoderma gangrenosum – a report of seven cases and review of the literature

Berth-Jones J, Tan SV, Graham-Brown RAC, Pembroke AC. J Dermatol Treat 1989; 1: 23–5.

Seven cases improved on minocycline at doses of 100 mg twice daily or 200 mg twice daily. Improvement was often observed within a few days.

Successful treatment of pyoderma gangrenosum with topical 0.5% nicotine cream

Patel GK, Rhodes JR, Evans B, Holt PJ. J Dermatol Treat 2004; 15: 122–5.

Two cases responded to nicotine in cetomacrogol cream.

There are also reports of PG responding to nicotine chewing gum, application of nicotine patches to lesions, and application of Swedish moist snuff containing nicotine.

Successful treatment of severe pyoderma gangrenosum with pimecrolimus cream 1%

Bellini V, Simonetti S, Lisi P. J Eur Acad Dermatol Venereol 2008; 22: 113–5.

A patient was cleared of PG lesions within 8 weeks using pimecrolimus cream twice daily.

Pyoderma gangrenosum. A study of 19 cases

Perry HO, Brunsting LA. Arch Dermatol 1957; 75: 380–6.

Six out of seven patients with PG associated with colitis demonstrated a good response to sulfasalazine 0.5 g every 3 hours. A good response was also seen in three of four cases of PG when colitis was not present.

This drug may be particularly useful in cases of PG associated with inflammatory bowel disease, and it can also be effective in those that are not. The initial dose ranges from 0.5 to 2 g four times daily. Doses at the upper

end of this range are usually reduced for maintenance therapy.

The treatment of pyoderma gangrenosum with sodium cromoglycate

De Cock KM, Thorne MG. Br J Dermatol 1980; 102: 231–3.

Two cases responded to sodium cromoglycate aqueous solution (2% w/v, Rynacrom nasal spray). In one patient, healing occurred within 3 weeks.

This is a remarkably safe treatment. Solutions have been applied to lesions in concentrations from 1% to 4%. Various nasal sprays and nebulizer solutions have proved suitable for application. The solution can be sprayed on to the ulcer or applied on gauze or under occlusion with a hydrocolloid dressing. This drug may act by inhibiting neutrophil migration or cytotoxicity.

Second-Line Therapies

• Ciclosporin	B
• Systemic corticosteroids	B

Treatment of pyoderma gangrenosum with ciclosporin: results in seven patients

Elgart G, Stover P, Larson K, Sutter C, Scheibner S, Davis B, et al. J Am Acad Dermatol 1991; 24: 83–6.

Six of seven patients, including cases associated with rheumatoid disease and cryoglobulinemia, improved on ciclosporin, with four healing completely.

The response to ciclosporin seems to be fairly consistent. Because the toxicity of this drug is largely related to prolonged use, it can be a reasonably safe approach to gaining control of PG, which is often a brief, self-limiting illness. High doses have been used (5–10 mg/kg/day) and are probably safe for a few days in an urgent situation. However, it is likely that lower doses of 5 mg/kg/day will often be adequate.

Pyoderma gangrenosum. Clinical and laboratory findings in 15 patients with special reference to polyarthritis

Holt PJA, Davies MG, Saunders KC, Nuki G. *Medicine* 1980; 59: 114–33.

Twelve of these patients received, and responded to, corticosteroid treatment. Doses of up to 100 mg daily were required to induce remission.

Therapeutic efficacy in the treatment of pyoderma gangrenosum

Johnson RB, Lazarus GS. *Arch Dermatol* 1982; 118: 76–84.

Intravenous doses of methylprednisolone 1 g daily for 5 days induced prompt responses in three cases.

Systemic corticosteroids (prednisone/prednisolone) have been one of the most frequently used treatments for PG, and extensive published experience indicates that they are generally considered highly effective. High doses of 40 to 100 mg/day may be required, and the morbidity may be considerable. Lower doses of 7.5 to 20 mg daily are sometimes adequate for maintenance. Other systemic and topical agents are usually employed simultaneously in order to minimize the dose.

Comparison of the two most commonly used treatments for pyoderma gangrenosum: results of the STOP GAP randomised controlled trial

Ormerod AD, Thomas KS, Craig FE, Mitchell E, Greenlaw N, Norris J, et al. *BMJ* 2015; 350: h2956.

In this study with 112 randomized patients, prednisolone 0.75 mg/kg/day was compared with ciclosporin 4 mg/kg/day to a maximum dose of 75 and 400 mg/day, respectively. The treatments did not differ across a range of objective and patient-reported outcomes. At 6 months, 47% of ulcers had healed in each group. Infections were more common serious adverse events in the group receiving prednisolone.

Third-Line Therapies

• Infliximab	A
• Other TNF α -antagonists	C
• Alkylating agents (cyclophosphamide, chlorambucil)	D
• Plasmapheresis (plasma exchange)	E
• Leukocytapheresis	D
• Intravenous immunoglobulin	C
• Intralesional ciclosporin	E
• Tacrolimus (FK506)	D
• Azathioprine or mercaptopurine	D
• Colchicine	D
• Thalidomide	D
• Potassium iodide	E
• Topical nitrogen mustard (mechlorethamine)	E
• Mycophenolate mofetil	D
• GM-CSF	E
• Methotrexate	E
• Topical platelet-derived growth factor	E
• Platelet-rich plasma	E
• Recombinant human epidermal growth factor	E
• Clofazimine	D
• Hyperbaric oxygen	D
• Isotretinoin	E
• Anakinra	E
• Ustekinumab	E
• Imiquimod	E
• Visilizumab	E
• Topical phenytoin	D
• Surgical debridement, closure, graft, or flap	E

Infliximab for the treatment of pyoderma gangrenosum: a randomised, double blind, placebo controlled trial

Brooklyn TN, Dunnill MG, Shetty A, Bowden JJ, Williams JD, Griffiths CE, et al. Gut 2006; 55: 505–9.

A placebo-controlled trial with 30 subjects. Two weeks after an infusion of infliximab 5 mg/kg or placebo, significantly more patients in the infliximab group had improved. In a later, open-label phase, 29 patients received infliximab with 20 demonstrating a response.

Improvement of pyoderma gangrenosum and psoriasis associated with Crohn's disease with anti-tumor necrosis factor alpha monoclonal antibody

Tan MH, Gordon M, Lebwohl O, George J, Lebwohl MG. Arch Dermatol 2001; 137: 930–3.

Numerous case reports have further established the response to infliximab.

Treatment of pyoderma gangrenosum with etanercept

McGowan JW 4th, Johnson CA, Lynn A. J Drugs Dermatol 2004; 3: 441–4.

The first of several cases reported to respond to etanercept 25 to 50 mg twice weekly.

Adalimumab therapy for recalcitrant pyoderma gangrenosum

Fonder MA, Cummins DL, Ehst BD, Anhalt GJ, Meyerle JH. J Burns Wounds 2006; 5: e8.

In this case improvement occurred on treatment with adalimumab after infliximab had failed to improve the pyoderma.

Adalimumab for treatment of pyoderma gangrenosum

Pomerantz RG, Husni ME, Mody E, Qureshi AA. Br J Dermatol 2007; 157: 1274–5.

Improvement occurred in a case that had failed to respond to etanercept.

Conventional dosing regimens have been employed: 40 to 80 mg fortnightly with and without an initial loading dose of 80 mg.

Pyoderma gangrenosum. Response to cyclophosphamide

therapy

Newell LM, Malkinson FD. Arch Dermatol 1983; 119: 495–7.

A very refractory case of PG responded to cyclophosphamide 150 mg daily. Healing was evident after 14 days and almost complete after 109 days.

Intravenous cyclophosphamide pulses in the treatment of pyoderma gangrenosum associated with rheumatoid arthritis. Report of 2 cases and review of the literature

Zonana-Nacach A, Jimenez-Balderas FJ, Martinez-Osuna P, Mintz G. J Rheumatol 1994; 21: 1352–6.

Two patients improved on pulsed intravenous cyclophosphamide at doses of 500 mg/m² combined with oral corticosteroid. The first received three pulses over 5 weeks and the second seven pulses over 14 weeks. In both cases remission was subsequently maintained using oral cyclophosphamide 100 mg daily.

Chlorambucil is an effective corticosteroid-sparing agent for recalcitrant pyoderma gangrenosum

Burruss JB, Farmer ER, Callen JP. J Am Acad Dermatol 1996; 35: 720–4.

Chlorambucil, 2 mg to 4 mg daily, was successfully used in six cases, both alone and in combination with systemic corticosteroids.

Pyoderma gangrenosum – response to topical nitrogen mustard

Tsele E, Yu RCH, Chu AC. Clin Exp Dermatol 1992; 17: 437–40.

The application of nitrogen mustard 20 mg/100 mL in aqueous solution on gauze swabs proved helpful in a single case associated with IgA paraprotein that had resisted many other treatment modalities. Patients can prepare this solution at home using tap water. Plasmapheresis was also helpful in this case. This was performed weekly for 2 years, successfully controlling the PG during this time.

Plasmapheresis is a relatively safe treatment involving removal of plasma while returning the blood cells to the circulation. Exchanges have generally been performed once to three times weekly, and prompt responses have been reported.

Leukocytapheresis treatment for pyoderma gangrenosum

Fujimoto E, Fujimoto N, Kuroda K, Tajima S. Br J Dermatol 2004; 151:

1090–2.

Efficacy of granulocyte and monocyte adsorption apheresis for three cases of refractory pyoderma gangrenosum

Seishima M, Mizutani Y, Shibuya Y, Nagasawa C, Aoki T. *Ther Apher Dial* 2007; 11: 177–82.

Three patients improved after weekly treatments for 10 or 11 weeks.

Extracorporeal removal of leukocytes is reported to have been effective in several cases of PG occurring both in isolation and in association with ulcerative colitis and rheumatoid disease.

Intravenous immunoglobulin for pyoderma gangrenosum

Kreuter A, Reich-Schupke S, Stucker M, Altmeyer P, Gambichler T. *Br J Dermatol* 2008; 158: 856–7.

A series of seven cases successfully treated with 0.5 g/kg body weight per day over 2 or 3 consecutive days in combination with systemic steroids and other drugs.

Clearing of pyoderma gangrenosum by intralesional cyclosporin A

Mrowietz U, Christophers E. *Br J Dermatol* 1991; 125: 498–9.

A lesion on the shoulder improved after two injections in 1 week of 35 mg ciclosporin into the active edges and beneath the lesion. The injection was formulated by diluting Sandimmune with normal saline in a ratio of 1:3.

Recalcitrant pyoderma gangrenosum treated with systemic tacrolimus

Lyon CC, Kirby B, Griffiths CE. *Br J Dermatol* 1999; 140: 562–4.

A refractory case of peristomal PG responded to tacrolimus 0.15 mg/kg/day.

Successful therapy of refractory pyoderma gangrenosum and periorbital phlegmona with tacrolimus (FK506) in ulcerative colitis

Baumgart DC, Wiedenmann B, Dignass AU. *Inflamm Bowel Dis* 2004; 10: 421–4.

Two cases associated with ulcerative colitis responded to tacrolimus 0.1 mg/kg/day.

Crohn's disease with cutaneous involvement

Parks AG, Morson BC, Pegum JS. Proc R Soc Med 1965; 58: 241.

Mercaptopurine was used at the dose of 75 mg/day with prednisone 20 mg/day.

Mercaptopurine is the active metabolite of azathioprine. Azathioprine has often been employed for PG, both alone and as a steroid-sparing agent. Doses have generally ranged from 100 to 150 mg daily. Less often, higher doses of up to 2.5 mg/kg/day are used. This drug seems useful in some cases, but results are not consistent.

Treatment of pyoderma gangrenosum with colchicine

Paolini O, Hebuterne X, Flory P, Charles F, Rampal P. Lancet 1995; 345: 1057–8.

Colchicine, 1 mg daily, was effective and well tolerated in PG associated with Crohn colitis.

Case report. Severe pyoderma associated with familial Mediterranean fever: favorable response to colchicine in three patients

Lugassy G, Ronnen M. Am J Med Sci 1992; 304: 29–31.

Treatment was commenced at 2 mg/day and reduced to 1 mg/day for maintenance.

Pyoderma gangrenosum with severe pharyngeal involvement

Buckley C, Bayoumi AHM, Sarkany I. J R Soc Med 1990; 83: 590–1.

A refractory case responded to thalidomide 100 mg daily.

Pyoderma gangrenosum chez un enfant: traitement par la thalidomide

Venencie PY, Saurat J-H. Ann Pediatr 1982; 1: 67–9.

A 3-year-old child refractory to other treatments responded well to thalidomide 150 mg daily.

Pyoderma gangrenosum associated with Behçet's syndrome – response to thalidomide

Munro CS, Cox NH. Clin Exp Dermatol 1988; 13: 408–10.

A case refractory to prednisolone 100 mg daily combined with dapsone 100 mg daily responded within 48 hours to thalidomide 400 mg daily.

This drug may be of particular value in cases associated with Behçet

disease, as it is also reportedly effective in severe aphthous ulceration.

Successful treatment of pyoderma gangrenosum with potassium iodide

Akihiko A, Yohei M, Yayoi T, Hiroshi M, Kunihiro T. *Acta Derm Venereol* 2006; 86: 84–5.

Oral KI 900 mg/day was added to prednisolone 17.5 mg, dapsone 50 mg, and minocycline 200 mg daily, which had not been effective. Improvement was observed within a few days. The dose of potassium iodide was increased to 1200 mg/day after 2 weeks, and the PG had disappeared almost completely after 1 month.

Potassium iodide has also been used to treat Sweet syndrome.

Mycophenolate mofetil in pyoderma gangrenosum

Lee MR, Cooper AJ. *J Dermatol Treat* 2004; 15: 303–7.

Mycophenolate 1 to 2.5 g daily was used in combination with prednisolone in three cases and as monotherapy (with 500 mg twice daily) in one.

Mycophenolate has most often been used in combination with other agents, such as ciclosporin and corticosteroids.

Pyoderma gangrenosum in myelodysplasia responding to granulocyte macrophage-colony stimulating factor (GM-CSF)

Bulvic S, Jacobs P. *Br J Dermatol* 1997; 136: 637–8.

A case responded to subcutaneous GM-CSF in a dose of 400 mg daily.

Pyoderma gangrenosum successfully treated with perilesional GM-CSF

Shapiro D, Gilat D, Fisher-Feld L, Shemer A, Gold I, Trau H. *Br J Dermatol* 1998; 138: 368–9.

In this case the GM-CSF was injected perilesionally at a weekly dose of 400 mg for 4 weeks.

The use of this agent has also been reported to aggravate PG. A variety of hypersensitivity reactions, including anaphylaxis, have occasionally occurred.

Treatment of pyoderma gangrenosum with methotrexate

Teitel AD. *Cutis* 1996; 57: 326–8.

A case failing to respond to prednisone 60 mg daily improved

within 2 weeks of adding methotrexate 15 mg weekly.

Topical platelet-derived growth factor accelerates healing of myelodysplastic syndrome-associated pyoderma gangrenosum

Braun-Falco M, Stock K, Ring J, Hein R. Br J Dermatol 2002; 147: 829–31.

Complete healing occurred over 9 weeks in this case after becaplermin was added to the treatment regimen.

Autologous platelet rich plasma in pyoderma gangrenosum – two case reports

Budamakuntla L, Suryanarayan S, Sarvajnamurthy SS, Hurkudli SD. Indian J Dermatol 2015; 60: 204–5.

These cases improved after 20 days and 5 weeks of once-weekly applications.

Recombinant human epidermal growth factor enhances wound healing of pyoderma gangrenosum in a patient with ulcerative colitis

Kim TY, Han DS, Eun CS, Chung YW. Inflamm Bowel Dis 2008; 14: 725–7.

Another case reported to improve in response to topical application of a growth factor.

Clofazimine. A new agent for treatment of pyoderma gangrenosum

Michaelsson G, Molin L, Ohman S, Gip L, Lindstrom B, Skogh M. Arch Dermatol 1976; 112: 344–9.

A good response was observed in eight cases using 300 to 400 mg daily.

Pyoderma gangrenosum treated with hyperbaric oxygen therapy

Wasserteil V, Bruce S, Sessoms SL, Guntupalli KK. Int J Dermatol 1992; 31: 594–6.

Hyperbaric oxygen has been reported as beneficial in several cases of PG. However, like all other treatments, it is not effective in all cases. This treatment may be worth trying when facilities are available.

Superficial pyoderma gangrenosum responding to treatment

with isotretinoin

Proudfoot LE, Singh S, Staughton RC. Br J Dermatol 2008; 159: 1377–8.

A previously refractory case of PG responding to isotretinoin 0.25 mg/kg/day.

Do not forget there are reports of isotretinoin therapy inducing exacerbations of inflammatory bowel disease and PG-like eruptions.

Targeted treatment of pyoderma gangrenosum in PAPA (pyogenic arthritis, pyoderma gangrenosum and acne) syndrome with the recombinant human interleukin-1 receptor antagonist anakinra

Brenner M, Ruzicka T, Plewig G, Thomas P, Herzer P. Br J Dermatol 2009; 161: 1199–201.

A single case of PG associated with an autosomal dominant genodermatosis.

A case of PG associated with inflammatory bowel disease has been reported not to respond.

Interleukin 23 expression in pyoderma gangrenosum and targeted therapy with ustekinumab

Guenova E, Teske A, Fehrenbacher B, Hoerber S, Adamczyk A, Schaller M, et al. Arch Dermatol 2011; 147: 1203–5.

A case healed on 45 mg subcutaneous ustekinumab, repeated after 4 weeks, in combination with topical tacrolimus.

Experience of using this drug for PG remains limited to a further couple of case reports.

Penile pyoderma gangrenosum successfully treated with topical imiquimod

Rathod SP, Padhiar BB, Karia UK, Shah BJ. Indian J Sex Transm Dis 2011; 32: 114–7.

A case of refractory penile ulceration of 18 months' duration was treated with imiquimod 5% cream once a day for 4 weeks. The lesion healed after 3 weeks.

Monoclonal gammopathy of undetermined significance related pyoderma gangrenosum successfully treated with autologous peripheral blood stem cell transplantation

Chang CM, Hwang WL, Hsieh ZY, Wang RC, Teng CL. Ann Hematol 2010; 89: 823–4.

Refractory PG, and the paraprotein, resolved after autologous stem cell transplant.

Pyoderma gangrenosum treated successfully with visilizumab in patients with ulcerative colitis

Lorincz M, Kleszky M, Szalóki T Jr, Szalóki T. Orv Hetil 2010; 151: 144–7.

A long-standing case of PG resolved 6 months after administration of visilizumab, two doses of 5 µg/kg intravenously. This is a T-cell-suppressing monoclonal antibody to CD3.

Two percent topical phenytoin sodium solution in treating pyoderma gangrenosum: a cohort study

Fonseka HF, Ekanayake SM, Dissanayake M. Int Wound J 2010; 7: 519–23.

A 2% suspension, prepared by mixing phenytoin sodium powder from capsules with normal saline, was applied to the lesions daily on gauze. Four cases of varied etiology healed, and two improved within 4 weeks—an inexpensive therapy.

Split skin grafts in the treatment of pyoderma gangrenosum: a report of four cases

Cliff S. Dermatol Surg 1999; 25: 299–302.

Free flap coverage of pyoderma gangrenosum leg ulcers

Classen DA, Thomson C. J Cutan Med Surg 2002; 6: 327–31.

Extensive abdominal wall and genital pyoderma gangrenosum: combination therapy in unusual presentations

Shahmoradi Z, Mokhtari F, Pourazizi M, Abtahi-Naeini B, Saffaei A. J Cutan Aesthet Surg 2014; 7: 238–40.

In this case surgical debridement and closure of the lesions by suturing were undertaken successfully in combination with corticosteroid therapy.

Surgical techniques can successfully accelerate healing when the PG is no longer active or is effectively suppressed by medical treatment. However, caution is required, because active PG often demonstrates the Koebner phenomenon.

Pyogenic granuloma

Danielle M. DeHoratius

Pyogenic granuloma (PG), also known as a *lobular capillary hemangioma*, is a common benign vascular growth. It often develops rapidly into a solitary erythematous papule or polyp. PGs are often friable and hemorrhagic and frequently ulcerate. They most commonly occur in children and young adults. The etiology is

unclear, although reactive neovascularization is suspected because of their occurrence at sites of previous trauma. They have also been reported as a cutaneous adverse effect of various medications. There is no gender or racial predominance. The most common locations are the head and neck region (including the oral mucosa, especially in pregnant women, known as *granuloma gravidarum*) and digits. Occasionally, PGs have been found in subcutaneous or intravascular locations. The term *PG* is a misnomer — there is no infectious or granulomatous component to these lesions.

Management Strategy

Histologic confirmation is beneficial, as other disorders may clinically mimic PGs, examples being amelanotic melanoma, Kaposi sarcoma, and bacillary angiomatosis. Dermoscopy of these lesions can be useful but should not substitute for histology. The most sensitive and specific pattern is a reddish homogeneous area, white collarette, and white rail lines.

Although they can eventually resolve spontaneously, treatment is usually required. Because this is a benign growth, it is important to consider the cosmetic outcome of the therapeutic intervention. PGs are most commonly treated by destruction using *shave excision with electrocautery* to the base, *curettage with electrodesiccation*, or *cryotherapy*. There is a possibility of recurrence and/or the development of satellite lesions, but these options are less invasive than excision and do not result in significant scarring. Complete *excision* requiring sutures may lower the recurrence rate and reduce the possibility of bleeding; however, a linear scar will be present. Hemostasis can be obtained by electrocautery, silver nitrate, or argon laser photocoagulation.

Vascular *lasers* also destroy these lesions, although multiple treatments are usually required, and there is no histologic confirmation. *Pulsed dye laser* has proved to be more successful with smaller lesions. For larger lesions the *Nd:YAG laser* has been efficacious. *Sclerotherapy* destroys these vascular lesions and has been reported to have a very high cure rate in experienced hands. Various application schedules of *imiquimod* 5% have resolved these lesions, presumably due to its antiangiogenic properties. Recently success has been reported using topical *timolol* 0.05% ophthalmic gel. *Photodynamic therapy* has been shown to be effective with very few adverse events.

Specific Investigation

- Histology

First-Line Therapies

• Simple shave excision/curettage with electrocautery of the base	A
• Full-thickness skin excision	A
• Cryotherapy	A
• Silver nitrate cautery	D

Pyogenic granuloma in children

Pagliai KA, Cohen BA. *Pediatr Dermatol* 2004; 21: 10–3.

A retrospective study of 128 children, including follow-up phone interviews of 76. Of these, 72.3% underwent a shave excision with electrocautery. The second most common treatment was laser therapy (16.9%). Fifty-five percent of the children in the first group reported a subtle scar, and 33% of the CO₂ laser group and 44% of the pulsed dye laser group reported a similar scar. All patients were pleased with the cosmetic result.

Comparison of cryotherapy and curettage for the treatment of pyogenic granuloma: a randomized trial

Ghodsi SZ, Raziel M, Taheri A, Karami M, Mansoori P, Farnaghi F. *Br J Dermatol* 2006; 154: 671–5.

Eighty-nine patients were treated with either liquid nitrogen cryotherapy or curettage followed by electrodesiccation. Of the 86 patients who completed the study, all had complete resolution of the lesions after one to three sessions (mean 1.42) in the cryotherapy group and after one to two sessions (mean 1.03) in the curettage group. No scar or residual pigmentation was reported in 57% of the cryotherapy group or in 69% of the curettage group. The authors concluded that curettage should be a first-line therapy as fewer treatment sessions were necessary and cosmesis was better.

Treatment of pyogenic granuloma by shave excision and laser photocoagulation

Kirschner R, Low D. *Plast Reconstruct Surg* 1999; 104: 1346–9.

Shave excision was performed on the exophytic portion and photocoagulation of the base through a glass slide. The lasers used were an argon, argon-pumped tunable yellow dye, or KTP laser. All treatments were performed until complete hemostasis was achieved. Complete resolution was seen in 18 of the 19 patients after a single treatment. Of note, the preoperative diagnosis was erroneous in 18.8% of the cases.

The efficacy of silver nitrate cauterization for pyogenic granuloma of the hand

Quitkin HM, Rosenwasser MP, Strauch RJ. *J Hand Surg Am* 2003; 28: 435–8.

Thirteen lesions were treated with simple removal and cautery of the base using silver nitrate. Eighty-five percent of the lesions resolved with an average of 1.6 treatments. The average time to complete healing was 3.5 weeks. There was no need for expensive equipment, and this was simple and cost effective.

Pyogenic granuloma – the quest for optimum treatment. Audit of treatment of 408 cases

Giblin AV, Clover AJ, Athanassopoulos A, Budny PG. *Plast Reconstruct Aesthet Surg* 2007; 60: 1030–5.

A retrospective study of 408 cases analyzed between 1994 and 2004. The excision and direct closure group had the fewest recurrences.

Cryotherapy in the treatment of pyogenic granuloma

Mirshams M, Daneshpazhooh M, Mirshekari A, Taheri A, Mansoori P, Hekmat S. *J Eur Acad Dermatol Venereol* 2006; 20: 788–90.

A prospective study of 135 patients treated with liquid nitrogen cryotherapy using a cotton-tipped applicator. Patients required anywhere from one to four treatments (mean 1.58). All patients had complete resolution, with 96.2% occurring after three treatments. Minor scars were reported in 11.8%, and 5.1% had hypopigmentation.

These authors report that cryotherapy should be considered first-line therapy as it is an easy and inexpensive technique; however, the main limitation is that no tissue is obtained for histology.

Second-Line Therapies

• Pulsed dye	B
• CO ₂ laser	B
• Nd:YAG laser	B

Treatment of pyogenic granuloma in children with the flashlamp-pumped pulsed dye laser

Tay YK, Weston WL, Morelli JG. Pediatrics 1997; 99: 368–70.

Twenty-two children with solitary lesions were treated with a vascular-specific (585 nm), pulsed (450 ms) dye laser using a 5-mm spot size with energy of 6 to 7 J/cm² without anesthesia. This treatment was successful in 91%, and all healed without scarring. Fifteen patients required from two to six treatments at 2-week intervals, and seven required three or more. The two patients who did not respond had larger lesions (0.5–1 cm). No recurrences were reported during the follow-up period (6 months to 3 years). The limitation of this laser modality was that the depth of penetration was only 1 mm.

This can be a useful modality in children, as no anesthesia is required and there is minimal scarring. The drawback is that no tissue is obtained for histology.

The combined continuous-wave/pulsed carbon dioxide laser for treatment of pyogenic granuloma

Raulin C, Greve B, Hammes S. Arch Dermatol 2002; 138: 33–7.

One hundred patients were treated. The laser was first used in the continuous mode (power 15 W) and then in the pulsed mode (pulse length 0.6–0.9 ms; energy fluence 500 mJ/pulse). Follow-up was 6

weeks and 6 months, and 98 of 100 patients had complete resolution after one treatment. In 88 patients there were no visible scars, and 10 had only slight textural changes. No erythema or pigmentary changes were observed.

Pyogenic granulomas: treatment with the 1064-nm long-pulsed neodymium-doped yttrium aluminum garnet laser in 20 patients

Hammes S, Kaiser K, Pohl L, Metelmann HR, Enk A, Raulin C.
Dermatol Surg 2012; 38: 918–23.

Twenty patients required one to four treatment sessions (settings used: fluences 60–180 J/cm², spot size of 7 mm, and a pulse duration of 40 ms). Nineteen had recurrence-free healing (follow-up duration 6–22 months) with good cosmetic results. Only slight textural changes were noted. This can be a satisfactory laser modality, especially when the diameter of the lesion is larger.

Third-Line Therapies

• Ligation	E
• Imiquimod 5%	C
• Sclerotherapy	D
• Photodynamic therapy	D
• Intralesional corticosteroids	E
• Intralesional bleomycin	E
• Topical phenol	E
• Topical timolol, ophthalmic gel	E

Surgical pearl: ligation of the base of a pyogenic granuloma – an atraumatic, simple, and cost-effective procedure

Holbe HC, Frosch PJ, Herbst RA. J Am Acad Dermatol 2003; 49: 509–10.

A pedunculated PG was ligated using an absorbable suture tightly tied at the base. Over a few days the lesion became necrotic and fell off.

This was atraumatic and required no anesthesia, but there was also no histologic confirmation.

Pyogenic granuloma in ten children treated with topical imiquimod

Tritton SM, Smith A, Wong LC, Zagarella S, Fischer G. Pediatr Dermatol 2009; 26: 269–72.

Children with a mean age of 2.5 years were instructed to apply imiquimod 5% once a day, twice a day, or three times per week, depending on the clinical response. They were assessed either weekly or biweekly. All lesions were located on the face (3–6 mm), and local erythema was unanimously observed. Three had no residual disease, whereas five had either small hypopigmented or erythematous lesions, which were continuing to improve at the completion of the study. No systemic side effects were reported.

The authors suggest a trial of three times per week initially, increasing to daily if tolerated, for up to 2 months. Treatment should be discontinued 1 week after complete disappearance of the lesion. This appears a reasonable alternative to surgical excision.

Treatment of pyogenic granuloma by sodium tetradecyl sulfate sclerotherapy

Moon SE, Hwang EJ, Cho KH. Arch Dermatol 2005; 141: 644–6.

Fifteen PGs were injected with 0.5% sodium tetradecyl sulfate until blanching appeared. Follow-up was every 1 to 2 weeks, and at 6 weeks 80% showed complete resolution. In two patients a small shallow vascular area remained, which responded to the CO₂ laser.

The authors felt that this treatment can be an alternative to excision because of its simplicity and lack of scarring; however, multiple treatments may be necessary to achieve resolution. There is no tissue for histologic sampling.

Photodynamic therapy with 5-aminolevulinic acid intralesional

injection for pyogenic granuloma

Lee DJ, Kim EH, Jang YH, Kim YC. Arch Dermatol 2012; 148: 126–8.

Fourteen lesions were injected (26-gauge needle) with 0.3 mL/cm³ of 5-aminolevulinic acid, 20% solution, followed by occlusion with polyurethane film. The lesions were then illuminated with red light (600–720 nm, light dose 100 J/cm², and fluence 100 mW/cm²). Eleven patients showed a marked response and had no recurrence at 1-year follow-up. One patient showed moderate response (lesion was on the lip), and two did not respond (lesions large >1 cm). Only three patients complained of perilesional swelling.

The authors felt that this treatment can be an alternative to standard therapy, especially in patients with small lesions who refuse surgery. It is important to consider the location and size of the lesion. Intralesional was suggested to be more effective than topical application of the photosensitizer.

Pyogenic granuloma that responded to local injection of steroid

Niiyama S, Amoh Y, Katsuoka K. J Plast Reconstr Aesthet Surg 2009; 62: 153–4.

Two lesions were injected with triamcinolone acetonide 2 mg weekly for a total of seven to eight times. The lesions became smaller and were subsequently excised.

This can be used when the lesion is in an unfavorable location for simple excision.

Complete resolution of recurrent giant pyogenic granuloma on the palm of the hand following single dose of intralesional bleomycin injection

Daya M. J Plast Reconstr Aesthet Surg 2010; 63: e331–3.

A 63-year-old woman presented with a recurrent giant PG (5 cm × 6 cm). Previous treatments included surgical excision and intralesional steroids. The lesion was injected with a total of 8 mL of 0.5 mg/mL of bleomycin given under general anesthesia with tourniquet control. The lesion regressed after 2 months and did not recur. The patient reported only mild hypersensitivity within the scar.

Topical phenol as a conservative treatment for periungual pyogenic granuloma

Losa Iglesias ME, Becerro de Bengoa Vallejo R. Dermatol Surg 2010; 36: 675–8.

A report of 18 patients treated with a 98% phenol solution, three

applications of 1 minute each consecutively. The entire tumor and a small surrounding area turned white. The areas were then treated with 10% silver sulfadiazine and 10% povidone iodine and wrapped in sterile gauze. The frequency of additional treatments varied based on size. At 14 weeks all lesions had resolved. The treatments were well tolerated with no scarring or adverse events.

This approach is simple to perform, fairly inexpensive, and relatively pain free; however, recurrence is possible, and treatment may necessitate frequent office visits.

Pyogenic granuloma in a 5-month-old treated with topical timolol

Khorsand K, Maier M, Branding-Bennett HA. Ped Dermatol 2015; 32: 650–1.

An infant treated with topical 0.5% gel-forming solution. Regression was noted after 1 month, and there was no recurrence at 8 months.

This treatment can be very useful, especially in areas of significant scarring; however, the limitation would be a lack of histology.

Radiation dermatitis

Megan Rogge, and Joshua A. Zeichner

Courtesy of Mark Lebwohl, MD.

Radiation dermatitis is a common complication of cutaneous radiation exposure, most frequently from interventional radiologic procedures or treatment of malignancies. Acute radiation dermatitis typically occurs within 2 to 3 weeks of radiation exposure and is caused by damage to appendageal structures and basal keratinocytes. Acute radiation dermatitis manifests as erythema, edema, epilation, dry or wet desquamation, and blistering. Pain and pruritus often accompany these changes. The most widely used tools for assessment are the National Cancer Institute's Common Terminology Criteria for

Adverse Events and the Radiation Therapy Oncology Group, which both grade acute radiation dermatitis from 1 to 4. Chronic radiation dermatitis is defined as skin changes persisting 90 days after radiation exposure, and these changes result from radiation-induced dermal and vascular damage leading to atrophy, dyspigmentation, telangiectasia, fibrosis, ulceration, and necrosis (see figure). Radiation recall is a dermatitis developing at sites of prior radiation exposure, usually induced by chemotherapeutic drugs such as doxorubicin or dactinomycin.

Management Strategy

Despite advances in radiation technology aimed at reducing side effects, skin toxicity is still a significant problem. The goals of treatment consist of maintaining skin integrity, minimizing patient discomfort, and preventing trauma and infection. *Bland emollients* treat dry desquamation (painless peeling of the skin), whereas moist desquamation (painful, full-thickness loss of the epidermis) should be treated with *occlusive dressings to prevent infections*. *Topical corticosteroids* control pruritus and reduce inflammation. Patients should also avoid friction from tight-fitting clothing. *Topical silver sulfadiazine* (SSD) may provide prophylaxis against bacterial infection and aid in the healing process. Patients may gently wash the skin with water and mild soap and use antiperspirants.

Chronic radiation dermatitis is also treated symptomatically. Topical emollient creams and corticosteroids can be employed as needed. Skin necrosis or ulceration must be carefully monitored for signs of infection. For reduction of skin fibrosis, some recommend physical *massage* of the skin or oral supplements such as *pentoxifylline* and *vitamin E*. Telangiectasias can be treated with *pulse dye laser*.

Specific Investigations

- History of previous radiation exposure and chemotherapeutic drugs
- Evaluation of affected skin for development of malignancy

Radio-induced malignancies of the scalp about 98 patients with 150 lesions and literature review

Maalej M, Frikha H, Kochbati L, Bouaouina N, Sellami D, Benna F, et al. Cancer Radiother 2004; 8: 81–7.

Basal cell carcinomas are the most common malignancies to develop in the skin at sites of previous radiation exposure, especially on the head and the neck.

First-Line Therapies

Acute radiation dermatitis

• Topical corticosteroids	A
• Emollients	B
• Topical silver sulfadiazine	B

Chronic radiation dermatitis

• Pentoxifylline	B
• Vitamin E	B
• Pulsed dye laser (PDL)	C

Clinical practice guidelines for the prevention and treatment of acute and late radiation reactions from the MASCC Skin Toxicity Study Group

Wong RK, Bensadoun RJ, Boers-Doets CB, Bryce J, Chan A, Epstein JB, et al. Support Care Cancer 2013; 21: 2933–48.

This article provides evidence-based recommendations from randomized controlled trials (RCTs) with standardized measurement

of outcomes. Washing with water, with or without a mild soap, and allowing use of antiperspirants are supported by RCT, as well as topical prophylactic corticosteroids to reduce pain and pruritus. There is some evidence that SSD cream can reduce dermatitis score. For chronic radiation dermatitis, the panel suggests use of PDL, pentoxifylline, and vitamin E.

A potent steroid cream is superior to emollients in reducing acute radiation dermatitis in breast cancer patients treated with adjuvant radiotherapy. A randomised study of betamethasone versus two moisturizing creams

Ulf E, Maroti M, Serup J, Falkmer U. *Radiother Oncol* 2013; 108: 287–92.

Betamethasone-17-valerate cream was compared with a moisturizer with and without 5% urea in this double-blinded RCT of 102 patients who underwent 5 weeks of radiation therapy (RT). The creams were applied twice per day for 7 weeks beginning with the start of RT. Radiation dermatitis scores were significantly improved in the topical betamethasone group at week 4 and 5. Itch, burning, and irritation were significantly improved in the betamethasone group at week 6.

Topical silver sulfadiazine for the prevention of acute dermatitis during irradiation for breast cancer

Hemati S, Asnaashari O, Sarvizadeh M, Motlagh BN, Akbari M, Tajvidi M, et al. *Support Care Cancer* 2012; 20: 1613–8.

Topical SSD 1% cream was applied three times a day for the 3 consecutive days after weekly radiation treatment for 5 weeks and 1 week thereafter in women receiving radiation for breast cancer. Patients using the SSD cream developed significantly less severe dermatitis as scored by a blinded observer compared with a control group who were treated with general skin care alone.

Striking regression of chronic radiotherapy damage in a clinical trial of combined pentoxifylline and tocopherol

Delanian S, Balla-Mekias S, Lefaix JL. *J Clin Oncol* 1999; 17: 3283–90.

Patients with radiation-induced fibrosis (RIF) for a mean period of 8.5 ± 6.5 years were treated with a combination of oral pentoxifylline 800 mg/day and vitamin E 1000 IU/day for at least 6 months and had mean RIF surface area, and subjective objective medical management and analytic injury evaluation scores improved significantly at 3, 6,

and 12 months.

Intense pulsed light vs. long-pulsed dye laser treatment of telangiectasia after radiotherapy for breast cancer: a randomized split-lesion trial of 2 different treatments

Nymann P, Hedelund L, Haedersdal M. Brit J Dermatol 2009; 160: 1237–41.

Thirteen patients with Fitzpatrick skin types II-III received a series of three treatments at 6-week intervals with long-pulsed dye (LPDL) (V-beam Perfecta, 595 nm) and intense pulsed light (Ellipse Flex). LPDL was superior in telangiectasia clearance, pain scores and patient satisfaction.

Second-Line Therapies

Acute radiation dermatitis

• Oral zinc supplement	A
• Hyaluronic acid cream	A
• Topical calendula	B
• Silver nylon dressing	B
• Film dressing	B
• Hydrogel or hydrocolloid dressing	B
• Topical trolamine	B
• Oral curcumin	A

Zinc supplementation to improve mucositis and dermatitis in patients after radiotherapy for head-and-neck cancers: a double-blind, randomized study

Lin LC, Que J, Lin LK, Lin FC. Int J Radiat Oncol Biol Phys 2006; 65: 745–50.

This double-blind, placebo-controlled RCT in patients with head-and-neck cancers receiving RT found that patients on an oral zinc supplement (25 mg Pro-Z), 3 tablets per day for approximately 2 months during RT, had a delayed grade 2 dermatitis, decreased development of grade 3 dermatitis, and overall milder dermatitis than those taking the placebo.

Double-blind, randomised clinical study comparing hyaluronic acid cream to placebo in patients treated with radiotherapy

Liguori V, Guillemin C, Pesce GF, Mirimanoff RO, Bernier J. Radiother Oncol 1997; 42: 155–61.

Patients who used hyaluronic acid 0.2% cream (Lalugenâ) twice per day for six weeks during RT had a delayed onset of acute dermatitis and significantly improved irradiated skin scores. This effect started at week 3 and continued through week 7, with no significant differences found between the groups in weeks 8 through 10.

Phase III randomized trial of *Calendula officinalis* compared with trolamine for the prevention of acute dermatitis during irradiation for breast cancer

Pommier P, Gomez F, Sunyach MP, D'Hombres A, Carrie C, Montbarbon X. J Clin Oncol 2004; 22: 1447–53.

At the onset of radiotherapy, Calendula or trolamine ointment were applied at least twice per day, by 254 women. Incidence of grade 2 to 3 acute skin toxicity and mean maximal pain scores were significantly less in the calendula treated group. Trolamine ointment was considered easier to apply.

Silver clear nylon dressing is effective in preventing radiation-induced dermatitis in patients with lower gastrointestinal cancer: results from a phase III study

Niazi TM, Vuong T, Azoulay L, Marijnen C, Bujko K, Nasr E, et al. Int J Radiat Oncol Biol Phys 2012; 84: e305–10.

Rectal or anal cancer patients undergoing RT were randomized to either use a silver clear nylon dressing (SCND) applied on day 1 of RT and worn continuously until 2 weeks after treatment completion or standard skin care comprising sulfadiazine cream applied at the time of skin dermatitis with photographs scored by blinded observers. On

the last day of RT, the mean dermatitis scores were significantly lower in the SCND-treated group compared with the standard group.

Effect of film dressing on acute radiation dermatitis secondary to proton beam therapy

Arimura T, Ogino T, Yoshiura T, Toi Y, Kawabata M, Chuman I, et al. *Int J Radiat Oncol Biol Phys* 2016; 95: 472–6.

In this trial of 271 patients undergoing proton beam therapy for prostate cancer, patients self-randomized to using a continuously applied film dressing (FD) with no medical ingredients, Airwall, or to standard treatment. Patients using the FD showed a significantly decreased grade 2 radiation dermatitis. Side effects of FD use included itching sensation, redness, and folliculitis.

RCT on gentian violet versus a hydrogel dressing for radiotherapy-induced moist skin desquamation

Gollins S, Gaffney C, Slade S, Swindell R. *J Wound Care* 2008; 17: 268–75.

Patients who used a hydrogel dressing (2nd Skin) continuously had a significantly increased area of healing with shortened healing time (12 days) as opposed to those who treated their skin with 0.5% aqueous gentian violet (GV) several times per day (30 days to heal on average). Furthermore, several of the GV patients dropped out of the study due to failure to heal and stinging upon application.

Curcumin for radiation dermatitis: a randomized, double-blind, placebo-controlled clinical trial of thirty breast cancer patients

Ryan JL, Heckler CE, Ling M, Katz A, Williams JP, Pentland AP, et al. *Radiat Res* 2013; 180: 34–43.

Patients taking the antioxidant, antiinflammatory curcumin (C3 Complexâ 2000 mg) three times daily during their RT were compared with a placebo group. The curcumin group had significantly decreased radiation dermatitis severity scores, and fewer patients had moist desquamation.

Third-Line Therapy

• Skin grafting

E

Chronic radiodermatitis injury after cardiac catheterization

Barnea Y, Amir A, Shafir R, Weiss J, Gur E. Ann Plast Surg 2002; 49: 668–72.

Two patients with painful, nonhealing wounds at the site of chronic radiation dermatitis underwent wound excision with grafting. The skin healed completely, but the pain was only partially relieved.

Raynaud disease and phenomenon

Dina Ismail, and Ian Coulson

Raynaud phenomenon (RP) is characterized by intermittent peripheral vasoconstriction leading to pallor, cyanosis, and reactive vasodilatation of the arterioles of the fingers and toes. It is caused by vasospasm in response to cold, emotion, hormones, and certain vasospastic drugs. Primary Raynaud disease is a milder, idiopathic form, whereas secondary RP coexists with autoimmune connective tissue disorders such as systemic lupus erythematosus and systemic

sclerosis (SSc) or other conditions that reduce blood flow, such as localized structural abnormalities. The pathogenesis and pathophysiology vary between the primary (idiopathic) and the secondary forms, but are still not fully understood.

Primary Raynaud disease is often mild and may not require treatment; the vasospasm is entirely reversible. However, secondary Raynaud disease often involves fixed blood vessel damage in addition to vasospasm; therefore the ischemia can be more severe. Complications include digital ulcers and gangrene, which can lead to amputation.

Management Strategy

Treatment is often nonpharmacologic, including avoiding cold (especially sudden drops in temperature) and smoking cessation. The use of *warming devices* such as hand or toe warmers is beneficial. Avoidance of triggers should be stressed (e.g., use of vibratory equipment). Drugs that may exacerbate the condition include β -blockers, bleomycin, caffeine, cisplatin, ergot preparations, interferon, methysergide, nicotine, oral contraceptives, reboxetine, tegaserod, and vinblastine and should be avoided.

Calcium channel antagonists, such as *nifedipine* (10–60 mg daily), are considered first-line treatment. The side effect profile includes hypotension, vasodilatation, peripheral edema, and headaches. Other treatments that have been studied in randomized, controlled trials include *phosphodiesterase-5 inhibitors* (PDE-5) (e.g., *sildenafil*, 25–50 mg up to four times a day) and *nitrates* (*topical or oral*), *angiotensin II inhibitors*, and *selective serotonin reuptake inhibitor* (*fluoxetine* 20–60 mg daily). PDE-5 inhibitors are effective in patients who respond poorly to calcium channel antagonists as an alternative or adjunct and in patients with severe SSc-related RP. For more serious Raynaud disease or its complications, *prostacyclin* agonists may be used. This may be particularly useful for RP associated with connective tissue disease. Endothelin receptor blockade with *bosentan* (62.5 mg twice a day) has been demonstrated to reduce the number of new digital ulcers in scleroderma patients. However, it does not affect the healing period and has no effect on the number and severity of attacks of RP in those without ulcers.

Specific Investigations

- Nail fold capillaroscopy
- Screening serology: ANF estimation
- Anticentromere and anti-Scl-70 antibodies
- Rheumatoid factor
- Cryoglobulins
- Chest x-ray
- Pulmonary function tests
- Echocardiography

Careful history taking and clinical examination followed by investigation to detect potential underlying disease are essential: capillaroscopy and specific autoantibody tests are the most productive in aiding diagnosis.

Assessment of nailfold capillaroscopy by × 30 digital epiluminescence (dermoscopy) in patients with Raynaud phenomenon

Beltran E, Toll A, Pros A, Carbonell J, Pujol RM. Br J Dermatol 2007; 156: 892–8.

The sclerodermic pattern showed a sensitivity of 76.9% and a specificity of 90.9% in Sjögren syndrome (SS). A typical capillaroscopic pattern of SS was observed in 73% of cases of limited SS and in 82% of cases of diffuse SS. Patients with SS and dermatopolymyositis SS showed a nonspecific capillaroscopic pattern. All patients with primary RP presented a normal capillaroscopic pattern. A normal capillaroscopic pattern was also observed in 11 of 12 patients with pre-SS. This technical variation allows the identification of specific capillaroscopic patterns associated with connective tissue diseases. It also permits us to differentiate primary RP from secondary RP.

First-Line Therapies

• Calcium channel blockers	A
• Glyceryl trinitrate	A
• Prostacyclin analogs	A
• Phosphodiesterase-5 inhibitors	A

Calcium channel blockers for primary Raynaud's phenomenon

Ennis H, Hughes M, Anderson ME, Wilkinson J, Herrick AL.
Cochrane Database Syst Rev 2016; 25: CD002069.

A meta-analysis of seven randomized trials with 296 patients evaluating the effects of nifedipine and nicardipine in the treatment of primary RP only. A decrease in the frequency of attacks was reported for patients on a calcium channel blocker (CCB). Doses of nifedipine used included 10 to 20 mg three times daily and 30 to 60 mg sustained-release daily. Nicardipine doses ranged between 20 to 30 mg thrice daily and 50 mg long-acting preparation twice daily. Trials included were of moderate quality.

Head-to-head comparison of udenafil vs. amlodipine in the treatment of secondary Raynaud's phenomenon: a double-blind, randomized, cross-over study

Lee EY, Park JK, Lee W, Kim YK, Park CS-Y, Giles JT, et al.
Rheumatology 2014; 53: 658–64.

Twenty-nine patients with secondary RP associated with connective tissue diseases received udenafil 100 mg daily or amlodipine 10 mg daily for 4 weeks. Both decreased the rate of RP attacks with comparable efficacy.

Comparison of sustained-release nifedipine and temperature biofeedback for treatment of primary Raynaud phenomenon. Results from a randomized clinical trial with 1-year follow-up

Raynaud's Treatment Study Investigators. Arch Intern Med 2000; 160: 1101.

Patients with primary RP received sustained-release nifedipine (30

or 60 mg daily), placebo, or two different forms of biofeedback therapy for 1 year ($n = 313$). Nifedipine was the superior intervention and led to a 66% reduction in attacks compared with placebo.

A double-blind placebo controlled crossover randomized trial of diltiazem in Raynaud's phenomenon

Rhedda A, McCans J, Willan AR, Ford PM. J Rheumatol 1985; 12: 724–7.

The results showed a significant reduction in both frequency and duration of attacks of vasospasm in the hands using diltiazem 60 to 240 mg daily. There was no detectable difference in response between patients with primary and those with secondary RP.

Phosphodiesterase-5 inhibitors for the treatment of secondary Raynaud's phenomenon: systematic review and meta-analysis of randomised trials

Herrick AL, van den Hoogen F, Gabrielli A. Ann Rheum Dis 2013; 72: 1696.

Six randomized controlled trials (RCTs) were included: one with sildenafil (50 mg twice daily), one with modified-release sildenafil (200 mg once daily), three with tadalafil (20 mg on alternate days when used as add-on therapy), and 20 mg once daily. One study looked at vardenafil 10 mg twice daily. A meta-analysis showed PDE-5 inhibitors significantly decreased frequency and duration of RP attacks compared with placebo in secondary RP.

Comparison of intravenous infusions of iloprost and oral nifedipine in treatment of Raynaud's phenomenon in patients with systemic sclerosis: a double blind randomised study

Rademaker M, Cooke ED, Almond NE, Beacham JA, Smith RE, Mant TG, et al. Br Med J 1989; 298: 561–4.

This study compared the long-term effects of short-term intravenous infusions of iloprost (0.5–2 ng/kg/minute) with those of oral nifedipine in patients with SSc-associated RP. It was concluded that both iloprost and nifedipine are beneficial in the treatment of RP. However, side effects are common with nifedipine. Short-term infusions of iloprost provide long-lasting relief of symptoms. Side effects occur only during the infusions and are dose dependent.

A multi-centre, blinded, randomised, placebo-controlled,

laboratory-based study of MQX-503, a novel topical gel formulation of nitroglycerine, in patients with Raynaud phenomenon

Hummers LK, Dugowson CE, Dechow FJ, Wise RA, Gregory J, Michalek J, et al. *Ann Rheum Dis* 2013; 72: 62–7.

In this multicenter, double-blind, randomized, placebo-controlled, cross-over study, 37 subjects were treated with 0.5% or 1.25% nitroglycerine or placebo gel. There was significant improvement in skin blood flow compared with placebo.

MQX-503, a novel formulation of nitroglycerin, improves the severity of Raynaud's phenomenon

Chung L, Shapiro L, Fiorentino D, Baron M, Shanahan J, Sule S, et al. *Arthritis Rheum* 2009; 60: 870–7.

Patients with a clinical diagnosis of primary or secondary RP received 0.9% MQX-503 gel or matching placebo during the treatment period ($n = 219$). There was a 2-week, single-blind, run-in period to determine baseline severity, followed by a 4-week double-blind treatment. The intervention was well tolerated and more effective than placebo for the treatment of RP.

Sustained-release transdermal glyceryl trinitrate patches as a treatment for primary and secondary Raynaud's phenomenon

Teh LS, Manning J, Moore T, Tully MP, O'Reilly D, Jayson MI. *Br J Rheumatol* 1995; 34: 636–41.

In this randomized, double-blind, placebo-controlled, cross-over study patients with primary Raynaud disease and patients with RP secondary to SSc ($n = 21$) were included. Glyceryl trinitrate patches (0.2 mg/h) were found to be effective in reducing the number and severity of Raynaud attacks in both groups of patients.

Iloprost treatment in patients with Raynaud's phenomenon secondary to systemic sclerosis and the quality of life: a new therapeutic protocol

Milio G, Corrado E, Genova C, Amato C, Raimondi F, Almasio PL, et al. *Rheumatology* 2006; 45: 999–1004.

In this randomized study 30 patients were treated with iloprost given by intravenous infusion at progressively increasing doses (from 0.5–2 ng/kg/minute) over a period of 6 hours each day for 10 days in 2 consecutive weeks, with repeated cycles at regular intervals of 3

months for 18 months. The results were compared with those obtained in 30 other patients who received the same drug but with different dosing regimens. The total average daily duration of the attacks, the average duration of a single attack, and the average daily frequency of the attacks were reduced significantly in all treatment groups, but the comparison between the groups demonstrated significant differences between patients treated with the new protocol and the others at later times (12 and 18 months).

Oral iloprost in Raynaud's phenomenon secondary to systemic sclerosis: a multicentre, placebo-controlled, dose-comparison study

Black CM, Halkier-Sorensen L, Belch JJ, Ullman S, Madhok R, Smit AJ, et al. *Br J Rheumatol* 1998; 37: 952–60.

Oral iloprost 50 µg or 100 µg twice a day was effective in reducing the duration of attacks, but not the severity or frequency. In this study of 103 patients the 50-µg dose was better tolerated.

Negative reports about beraprost (another oral prostacyclin analog) and oral iloprost also exist.

Effects of long-term cyclic iloprost therapy in systemic sclerosis with Raynaud's phenomenon: a randomized controlled study

Scorza R, Caronni M, Mascagni B, Berruti V, Bazzi S, Micallef E, et al. *Clin Exp Rheumatol* 2001; 19: 503.

A 12-month prospective, randomized, parallel-group, blind-observer trial to compare the effects of intravenously infused iloprost (2 ng/kg/min on 5 consecutive days over a period of 8 hours/day and subsequently for 8 hours on 1 day every 6 weeks) with those of conventional vasodilating therapy with nifedipine (40 mg/day orally) in 46 patients with SSc and RP. Both iloprost and nifedipine were able to significantly reduce RP symptoms, with no differences between treatments.

Second-Line Therapies

• Selective serotonin reuptake inhibitors (fluoxetine)	B
• Endothelin receptor antagonist (bosentan)	B
• Angiotensin II receptor type I antagonist (losartan)	B
• Oral vasodilators	B
• Alpha-1-adrenergic receptor antagonist (prazosin)	A
• Hexopal	A

Treatment of Raynaud's phenomenon with the selective serotonin reuptake inhibitor fluoxetine

Coleiro B, Marshall SE, Denton CP, Howell K, Blann A, Welsh KI, et al. Rheumatology 2001; 40: 1038–43.

This pilot study compared fluoxetine, a selective serotonin reuptake inhibitor (20–60 mg/day), with nifedipine as treatment for primary or secondary RP. The results confirmed the tolerability of fluoxetine and suggest that it would be effective as a novel treatment for RP.

Bosentan treatment of digital ulcers related to systemic sclerosis: results from the RAPIDS-2 randomised, double-blind placebo-controlled trial

Matucci-Cerinic M, Denton CP, Furst DE, Mayes MD, Hsu VM, Carpentier P, et al. Ann Rheum Dis 2011; 70: 32–8.

This double-blind, placebo-controlled, multicenter trial randomized 188 patients with SSc with at least one active digital ulcer (DU) to bosentan 62.5 mg twice daily for 4 weeks and 125 mg twice daily thereafter for 20 weeks or placebo. Bosentan was found to reduce the occurrence of new DUs compared with placebo in patients with SSc but had no effect on DU healing.

Losartan therapy for Raynaud's phenomenon and scleroderma: clinical and biochemical findings in a fifteen-week, randomized, parallel group, controlled trial

Dziadzio M, Denton CP, Smith R, Howell K, Blann A, Bowers E, et al. Arthritis Rheum 1999; 42: 2646–55.

Treatment with losartan (50 mg daily) was shown to reduce the severity and frequency of attacks in primary and scleroderma RP at

12 weeks.

Double-blind, placebo-controlled study of prazosin in Raynaud's phenomenon

Wollersheim H, Thien T, Fennis J, van Elteren P, van 't Laar A. Clin Pharmacol Ther 1986; 40: 219–25.

In this study, prazosin 1 mg thrice daily was compared with placebo and showed a moderate subjective improvement with a reduction in daily number and duration of attacks. No differences in treatment response were identified between patients with Raynaud disease and secondary RP.

Dose-response study of prazosin in Raynaud's phenomenon: clinical effectiveness versus side effects

Wollersheim H, Thien T. J. Clin Pharmacol 1988; 28: 1089–93.

In a dose-response study of prazosin in 24 patients with RP, the clinical effectiveness and side effects of 3, 6, and 12 mg prazosin administered daily were compared. No major differences among these three dose regimens were identified.

Oral vasodilators for primary Raynaud's phenomenon

Vinjar B, Stewart M. Cochrane Database Syst Rev 2008; 2: CD006687.

Two trials examined the effects of captopril; the rest were single trials of single drugs. For captopril, beraprost, dazoxiben, and ketanserin there was no evidence of an effect on the frequency, severity, or duration of attacks. Beraprost and moxisylyte gave significantly more adverse effects than placebo.

A double-blind randomized placebo controlled trial of Hexopal in primary Raynaud's disease

Sunderland GT, Belch JJ, Sturrock RD, Forbes CD, McKay AJ. Clin Rheumatol 1988; 7: 46–9.

Hexopal (hexanicotinate inositol) (2–4 g daily) is safe and effective in reducing the vasospasm of primary Raynaud disease during the winter months.

Third-Line Therapies

• Prostaglandin E ₁ (alprostadil)	B
• Dipyridamole and low-dose acetylsalicylic acid	B
• Calcitonin gene-related peptide	C
• L-Arginine	D
• Heating, Ozonation, UV (HOU) therapy	C
• Triiodothyronine	C
• <i>Helicobacter pylori</i> treatment	B
• Sympathectomy	C
• Low-level laser therapy	C
• Acupuncture	C
• Evening primrose oil supplementation	C
• Fish oil supplementation	B
• Botulinum toxin	A
• Spinal cord stimulation	E
• Rituximab	E
• Statins	A
• Low-molecular-weight heparin	B

Efficacy evaluation of prostaglandin E1 against placebo in patients with progressive systemic sclerosis and significant Raynaud's phenomenon

Bartolone S, Trifilatti A, De Nuzzo G, Scamardi R, Larosa D, Sottilotta G, et al. *Minerva Cardioangiol* 1999; 47: 137–43.

Alprostadil infusions at 60 µg in 250 mL for 6 days reduced the frequency and severity of attacks in patients with secondary RP.

A double-blind controlled trial of low dose acetylsalicylic acid

and dipyridamole in the treatment of Raynaud's phenomenon

Van der Meer J, Wouda AA, Kallenberg CG, Wesseling H. *Vasa* 1987; 18: 71–5.

This analgesic and antithrombotic combination (aspirin 50–100 mg/day, dipyridamole 200 mg twice a day) is safe and helpful in treating patients with RP who have severe digital ulceration.

Calcitonin gene-related peptide in treatment of severe peripheral vascular insufficiency in Raynaud's phenomenon

Bunker CB, Reavley C, O'Shaughnessy DJ, Dowd PM. *Lancet* 1993; 342: 80–3.

Calcitonin gene-related peptide, a potent vasodilator, given intravenously (0.6 µg/minute for 3 hours a day for 5 days) resulted in an increase in blood flow, ulcer healing, and effective vascular dilation in patients with severe RP.

Oral L-arginine can reverse digital necrosis in Raynaud's phenomenon

Rembold CM, Ayers CR. *Mol Cell Biochem* 2003; 244: 139–41.

The authors demonstrate a beneficial response to oral L-arginine therapy (up to 8 g daily), which reversed digital necrosis and improved the symptoms of severe RP. This evidence suggests that a defect in nitric oxide synthesis or metabolism is associated with RP and demonstrates the potential effectiveness of L-arginine therapy.

Treatment of severe Raynaud's syndrome by injection of autologous blood pretreated by heating, ozonation, and exposure to ultraviolet light (H-O-U) therapy

Cooke ED, Pockley AG, Tucker AT, Kirby JD, Bolton AE. *Int Angiol* 1997; 16: 250–4.

Treatment was successful in patients with severe RP. Results included reduction of attacks for at least 3 months and, for some, no attacks at all.

Triiodothyronine treatment for Raynaud's phenomenon: a controlled trial

Dessin PH, Morrison RC, Lamparelli RD, van der Merwe CA. *J Rheumatol* 1990; 17: 1025–8.

In this trial T₃ 80 µg/day increased finger skin temperature and

reduced recovery times after cold exposure. Treatment is recommended for patients with severe RP and digital ulcers.

***Helicobacter pylori* eradication ameliorates primary Raynaud's phenomenon**

Gasbarrini A, Massari I, Serrichio M, Tondi P, De Luca A, Franceschi F, et al. Dig Dis Sci 1998; 43: 1641–5.

Of 46 RP patients, 36 were infected with *H. pylori*. After treatment to eradicate *H. pylori*, RP disappeared in 17% of patients; 72% of the remaining patients noticed a reduction in frequency and duration of their vasospastic attacks.

The use of digital artery sympathectomy as a salvage procedure for severe ischemia of Raynaud's disease and phenomenon

McCall TE, Petersen DPM, Wong LB. J Hand Surg [Am] 1999; 24: 173–7.

In six of seven patients the use of digital artery sympathectomy was effective; the patients' digital ulcers healed and amputation was avoided.

Double-blind, randomised, placebo controlled low laser therapy study in patients with primary Reynaud's phenomenon

Hirschl M, Katzenschlager R, Ammer K, Melnizky P, Rathkolb O, Kundi M, et al. Vasa 2002; 31: 91–4.

This study examined 15 patients with primary RP and demonstrated that low-level laser therapy reduced the intensity of the attacks during laser irradiation without significantly affecting the frequency of attacks. Additionally, after laser irradiation the temperature gradient after cold exposure was reduced, but there was no effect on the number of fingers showing prolonged rewarming.

Treatment of primary Raynaud's syndrome with traditional Chinese acupuncture

Appiah R, Hiller S, Caspary L, Alexander K, Creutzig A. J Intern Med 1997; 241: 119–24.

Thirty-three patients with primary Raynaud disease (16 controls, 17 treatment) were studied. Overall, attacks were reduced by 63%.

Evening primrose oil (Efamol) in the treatment of Raynaud's phenomenon: a double-blind study

Belch JJ, Shaw B, O'Dowd A, Saniabadi A, Leiberman P, Sturrock RD, et al. *Thromb Haemost* 1985; 54: 490–4.

Twenty-one patients were studied. Evening primrose oil (12 capsules daily) provided symptomatic improvement.

Fish-oil dietary supplementation in patients with Raynaud's phenomenon: a double blind controlled, prospective study

DiGiacomo RA, Kremer JM, Shah DM. *Am J Med* 1989; 86: 158–64.

In this trial involving 32 patients supplementation with omega-3 fatty acids (3.96 g eicosapentaenoic acid and 2.64 g docosahexaenoic acid) was shown to be of benefit in patients with primary, but not secondary, RP.

A 28-day prospective, randomized, double-blind, placebo controlled clinical trial of botulinum toxin type A for Raynaud's phenomenon

Webb KN, Berry NN, Bueno RA, Neumeister MW. *Plast Reconstr Surg* 2014; 133: 13.

Thirty-five patients were treated with either placebo or botulinum toxin type A (Btx-A) 100 U into the palm around involved digital neuromuscular bundles. Ten percent of placebo patients reported pain relief compared with 62% of Btx-A–treated patients ($p = 0.0288$). Average pain relief duration was 127 days, and 60% of patients with digital ulcers healed after Btx-A injection.

Clinical and objective data on spinal cord stimulation for the treatment of severe Raynaud's phenomenon

Neuhauser B, Perkmann R, Klingler PJ, Giacomuzzi S, Kofler A, Fraedrich G, et al. *Am Surg* 2001; 67: 1096–7.

Spinal cord stimulation was shown to effectively improve red blood cell velocity, capillary density, and capillary permeability in a 77-year-old woman with severe RP.

Severe primary Raynaud's disease treated with rituximab

Shabrawishi M, Albeity A, Almoallim H. *Case Rep Rheumatol* 2016; 2016: 2053804.

A case of a 55-year-old female with primary RP who failed first-line therapies. Due to persistent symptoms, rituximab therapy was initiated (1 g 2 weeks apart) with complete resolution of digital ischemia. Recurrence of symptoms resolved after a second cycle of

rituximab (375mg/m² weekly for 4 weeks). Full remission was achieved.

Statins: potentially useful in therapy of systemic sclerosis-related Raynaud's phenomenon and digital ulcers

Abou-Raya A, Abou-Raya S, Helmii M. J Rheumatol 2008; 35: 1801.

This randomized trial involving 84 patients demonstrated that atorvastatin 40 mg daily for 4 months reduced overall number of digital ulcers, severity, and pain in SSc-related RP.

Long-term beneficial effects of statins on vascular manifestations in patients with systemic sclerosis

Kuwana M, Okazaki Y, Kaburaki J. Mod Rheumatol 2009; 19: 530.

A 24-month, open-label trial where patients received atorvastatin 10 mg daily. RP improved during treatment, with significant reductions in the Raynaud's Condition Score and patient visual analog scale.

Long-term low molecular weight heparin therapy for severe Raynaud's phenomenon: a pilot study

Denton CP, Howell K, Stratton RJ, Black CM. Clin Exp Rheumatol 2000; 18: 499.

Low-molecular-weight heparin was used as an add-on therapy for patients with primary or secondary RP already receiving at least one oral anti-Raynaud agent. There was an improvement in attack severity after 4 weeks of heparin therapy, maximal by 20 weeks, compared with the control group.

Reactive arthritis

Clinton W. Enos, Sara Samimi, and Abby S. Van Voorhees

Reactive arthritis (ReA), formerly known as *Reiter syndrome*, is one of the reactive forms of seronegative spondyloarthropathies. It is both a genetically determined and immune-mediated disease that primarily affects the skin and joints 2 to 4 weeks after an enteric or urogenital infection. Commonly implicated gastrointestinal pathogens include *Yersinia*, *Salmonella*, *Shigella*, *Campylobacter*, and *Clostridium difficile*; common urogenital pathogens include *Chlamydia trachomatis*, *Neisseria gonorrhea*, and *Ureaplasma urealyticum*. Rarely, ReA can manifest after a respiratory infection with *Chlamydia pneumoniae* or group A β -hemolytic streptococcus. ReA is relatively rare condition that is more common in young adults ages 20 to 40.

There is no predilection for either sex when a gastrointestinal pathogen is the inciting agent; however, males have a greater incidence after *Chlamydia trachomatis* infection. The HLA-B27 allele has been associated with ReA, although it is not a diagnostic criterion.

ReA is a clinical diagnosis characterized by a triad of urethritis, conjunctivitis, and oligoarthritis; however, only roughly one third of patients present with a complete triad, making the diagnosis largely dependent on patient history. General guidelines set forth by the American College of Rheumatology (ACR) proposed major and minor criteria to aid in a definite diagnosis (see later). Similarly, European guidelines for sexually acquired ReA incorporate the recognition of a monoarthritis or oligoarthritis preceded by a symptomatic urethritis. Additional extraarticular findings can include enthesitis, tendinitis, bursitis, conjunctivitis, anterior uveitis, and keratitis. The classic skin manifestations include keratoderma blennorrhagica and circinate balanitis. Nail changes, oral lesions, and ulcerative vulvitis may also be seen. Erythema nodosum can also occur and is more common in the setting of a *Yersinia* infection. The differential diagnosis may include atopic dermatitis, Behçet disease, contact dermatitis, and pustular psoriasis.

Management Strategy

The mucocutaneous lesions of uncomplicated ReA are usually self-limited and clear within a few months. Severe, extensive, and chronic cutaneous presentations, which are more common in the setting of human immunodeficiency virus (HIV) infection, are generally treated in the same manner as pustular psoriasis. Initial therapy for limited skin disease includes *topical steroids, topical vitamin D preparations, tacrolimus, and tazarotene*. Second-line agents include *UVB and systemic retinoids*. Severe disease can be treated with *psoralen plus UVA (PUVA)* and *immunosuppressive agents such as methotrexate and ciclosporin*. *Anti-tumor necrosis factor (TNF)* agents have also been used successfully in patients with refractory disease as well as those with HIV, but data from randomized, placebo-controlled trials are lacking.

In most patients, the symptoms of arthritis and inflammation of the peripheral ligamentous or muscular attachments (entheses) dictate the focus of treatment. *Nonsteroidal antiinflammatory drugs (NSAIDs)* are the first-line therapy. *Corticosteroid injections* can provide temporary relief of the pain caused by arthritis or bursitis, and oral

corticosteroids may also be beneficial when severe. *Sulfasalazine* and *methotrexate* have been shown to be effective and well tolerated in cases refractory to both NSAIDs and steroids. *TNF inhibitors* have also shown efficacy in treating severe disease. Of note, emerging biologics such as ustekinumab, apremilast, and secukinumab have not been investigated in the treatment of ReA.

Transient and mild conjunctivitis does not require specific therapeutic intervention. Symptoms of eye pain or blurry vision require immediate referral to ophthalmology to determine whether these symptoms are due to conjunctivitis or a more serious eye problem such as uveitis, iritis, or keratitis. Treatment often involves topical and/or systemic corticosteroids and immunosuppressive medications such as methotrexate.

The effects of short-term and long-term *antibiotic therapy* for ReA are controversial. Although there is some evidence that antibiotics may be beneficial during the infectious phase before arthritis has developed, it is not clear whether the introduction of antibiotics after the development of arthritis will modify the disease course. A meta-analysis of 10 trials indicated that there is no significant benefit for the use of antibiotics in ReA. However, due to the heterogeneity of trials included in this analysis, the possible benefit of antibiotics in certain subgroups or at certain time points cannot be completely excluded. For example, a double-blind, placebo-controlled study suggested no advantage of combination antibiotics (roxithromycin and ofloxacin) over placebo in the treatment of recent-onset ReA, but another small study reports a beneficial effect of combination treatment with *doxycycline* and *rifampin* for chronic spondyloarthritis. If the inciting organism is documented by culture or polymerase chain reaction (PCR), antibiotics are indicated. The true benefits of antibiotics, their dosage, and their duration remain to be clarified. However, when evaluating a patient with ReA after a urogenital infection, it is also important to consider treatment of the patient's partner for further disease prevention.

ReA in HIV-infected individuals may be more prevalent, severe, and progressive because it is more refractory to treatment. However, one report describes ReA as part of an immune reconstitution syndrome that is rapidly responsive to a 2-week course of doxycycline. Another case report describes the resolution of ReA symptoms upon initiating antiretroviral therapy. The pathogenic link between HIV and ReA is not completely understood; however, case

reports highlight the benefit of closely comanaging HIV-1 infection and the symptoms of ReA.

Specific Investigations

- Recent history of gastrointestinal or genitourinary infection or symptoms
- Skin biopsy
- Urinalysis
- Urethral, cervical, and stool cultures
- Serum antibodies to chlamydia
- Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complete blood count
- HIV testing/status
- Rheumatoid factor and antinuclear antibody (ANA) (negative in reactive arthritis)
- Synovial fluid analysis
- Radiographic imaging
- HLA-B27 typing
- Ophthalmologic slit lamp examination
- Electrocardiogram (ECG) in chronic disease

Proposed Diagnostic Criteria by the ACR (1999)

Major criteria:

1. Arthritis with at least two of the following: asymmetry, monoarthritis or oligoarthritis, lower limb involvement
2. Preceding symptomatic infection
 - a. Enteritis that consists of diarrhea for at least 1 day, 3 days to 6 weeks before onset of arthritis
 - b. Urethritis that consists of dysuria for at least 1 day, 3 days to 6 weeks before onset of arthritis

Minor criteria:

1. Evidence of a triggering infection via one or both of the following:
 - a. Urine ligase reaction or urethral/cervical swab positive for *Chlamydia trachomatis*
 - b. Positive stool cultures for pathogens associated with ReA.
2. Evidence of persistent synovial infection via immunohistochemical or PCR studies for *Chlamydia*

A definite diagnosis includes both major criteria and a relevant

minor criterion. A probable diagnosis consists of both major criteria with no minor criteria, or one major criterion and one or more relevant minor criteria.

First-Line Therapies

Cutaneous disease

• Topical steroids	C
• Calcipotriene (calcipotriol)	E
• Tazarotene	E
• Tacrolimus	E

Reiter syndrome

Rothe MJ, Kerdel FA. Int J Dermatol 1991; 30: 173–80.

Mucocutaneous lesions may necessitate only local care for mucosal erosions and topical steroids for psoriasiform lesions.

Because treatment in ReA is typically directed toward the musculoskeletal component and urethritis, there is a paucity of studies designed for the treatment of cutaneous disease. However, despite the lack of controlled studies, topical steroids are accepted as first-line therapy for mild cutaneous lesions.

Successful treatment of chronic skin disease with clobetasol propionate and a hydrocolloid dressing

Volden G. Acta Derm Venereol 1992; 72: 69–71.

Two patients with skin lesions of reactive arthritis and 19 patients with palmoplantar pustulosis responded to clobetasol propionate lotion once weekly under occlusion. The mean interval to remission was 3 weeks for the skin lesions of ReA and 2.2 weeks for palmoplantar pustulosis.

Reiter's disease in a homosexual HIV-positive male

Vaughan Jones SA, McGibbon DH. Clin Exp Dermatol 1994; 19: 430–3.

A case report of a 32-year-old male with AIDS whose psoriasiform lesions improved after 2 weeks of topical corticosteroids and a course of flucloxacillin.

Tacrolimus therapy for circinate balanitis associated with reactive arthritis

Herrera-Esparza R, Medina F, Avalos-Diaz E. J Clin Rheumatol 2009; 15: 377–9.

A report of three patients with evidence of circinate balanitis refractory to systemic therapy with corticosteroids and sulfasalazine but responsive to treatment with topical tacrolimus 0.1%.

Reiter's disease in a 6-year-old girl

Arora S, Arora G. Indian J Dermatol Venereol Leprol 2005; 71: 285–6.

A case report of a 6-year-old child with ReA whose primary keratoderma blennorrhagicum lesions were treated with topical salicylic acid and hydrocortisone with complete resolution in 3 weeks.

The use of topical calcipotriene/calcipotriol in conditions other than plaque-type psoriasis

Thiers BH. J Am Acad Dermatol 1997; 37: S69–71.

A 47-year-old man with relapsing ReA, with pustules and hyperkeratotic plaques on his palms and soles, as well as circinate balanitis, responded to 14 days of doxycycline (100 mg twice a day) and topical calcipotriene.

Treatment of keratoderma blennorrhagicum with tazarotene gel 0.1%

Lewis A, Nigro M, Rosen T. J Am Acad Dermatol 2000; 43: 400–2.

A case report of a 64-year-old man with ReA who responded to daily application of tazarotene gel 0.1% to his soles.

Second-Line Therapies

Cutaneous disease

• Systemic retinoids	D
• UVB/PUVA	D
• Antiretroviral therapy	E

Acitretin and AIDS-related Reiter's disease

Blanche P. Clin Exp Rheum 1999; 17: 105–6.

A case report of a 46-year-old patient with AIDS and ReA whose arthritis and skin lesions responded to 2 weeks of acitretin (25 mg daily). Therapy was continued for 5 months; a recurrence occurred several months after the acitretin was stopped despite maintenance on antiretroviral therapy. Acitretin was resumed, resulting in prompt resolution of disease, and continued for 6 months. No recurrence was observed after 13 months.

Reiter's syndrome-like pattern in AIDS-associated psoriasiform dermatitis

Romani J, Puig L, Baselga E, De Moragas JM. Int J Dermatol 1996; 35: 484–8.

A retrospective review of seven HIV-positive patients with Reiter-like psoriasiform dermatitis. Etretinate alone and RePUVA (etretinate 1 mg/kg daily, 8-methoxypsoralen 0.6 mg/kg followed by UVA) were safe and effective in controlling skin disease. Methotrexate (15 mg weekly in three divided doses) was effective, but was complicated by hematologic toxicity in two patients. Ciclosporin (2.5 mg/kg daily) was moderately effective and was not associated with progression of AIDS.

Successful treatment of severe Reiter's syndrome associated with human immunodeficiency virus infection with etretinate. Report of 2 cases

Louthrenoo W. J Rheumatol 1993; 20: 1243–6.

A report of two cases of HIV-related ReA responding dramatically to 4 weeks of etretinate (0.5–1.0 mg/kg daily).

Reactive arthritis responding to antiretroviral therapy in an HIV-1-infected individual

Scott C, Brand A, Natha M. *Int J STD AIDS* 2012; 23: 373–4.

A report of an HIV-1 infected patient with severe ReA who failed conventional therapy with steroids, disease-modifying antirheumatic agents, and nonsteroidal antiinflammatory drugs but experienced resolution of ReA symptoms after initiation of antiretroviral therapy. Antiretroviral use may be beneficial for symptomatic relief, suggesting that patients should be managed closely by both rheumatology and infectious disease.

Human immunodeficiency virus associated spondyloarthropathy: pathogenic insights based on imaging findings and response to highly active antiretroviral treatment

McGonagle D, Reade S, Emery P. *Ann Rheum Dis* 2001; 60: 696–8.

Case report of a 31-year-old HIV-positive man with ReA with extensive polyarthralgia and osteitis. The patient's arthritis worsened despite treatment, including indomethacin, tramadol, and sulfasalazine, but improved dramatically after antiretroviral treatment (lamivudine, ritonavir, and stavudine). Improvement was accompanied by a significant rise in CD4 T-lymphocyte counts.

Clinical improvement of HIV-associated psoriasis parallels a reduction of HIV viral load induced by effective antiretroviral therapy

Fischer T, Ramadori G. *AIDS* 1999; 13: 628–9.

Case report of a 38-year-old HIV-positive male with viremia and psoriasis. The patient was started on multiple antiretroviral agents in addition to topical steroids and vitamin D₃ analogs. Despite antiretroviral therapy, his viral load remained high and his psoriasis persisted. It was not until his viral load decreased below 400 that his skin lesions started to improve.

Third-Line Therapies

Cutaneous disease

• Methotrexate	C
• Ciclosporin	E
• TNF inhibitors	C

A review of methotrexate therapy in Reiter syndrome

Lally EV, Ho G Jr. Semin Arthritis Rheum 1985; 15: 139–45.

A case report and review of the literature. Eighteen of 20 patients noted dramatic improvement in skin lesions within 2 weeks of receiving methotrexate; 15 of 20 patients had significant improvement in arthritis, although the response was generally slower. Methotrexate was generally well tolerated, but the drug had to be discontinued in three cases due to adverse effects. Methotrexate was used for exacerbations and was then discontinued after clinical improvement. The usual dosage was 10 to 50 mg/week administered either orally or parenterally.

Successful treatment of Reiter's syndrome in a patient with AIDS with methotrexate and corticosteroids

Berenbaum F, Duvivier C, Prier A, Kaplan G. Br J Rheumatol 1996; 35: 295.

A case report of a 37-year-old man with AIDS and severe ReA who responded to prednisone 20 mg daily and methotrexate 20 mg/week. This was combined with antiretroviral therapy, chemoprophylaxis of infection, and aggressive therapy of Kaposi sarcoma without exacerbation of his AIDS.

Successful treatment of severe recurrent Reiter's syndrome with cyclosporine

Kiyohara A, Ogawa H. J Am Acad Dermatol 1997; 36: 482–3.

A case report of a 48-year-old man with postchlamydia ReA not

responsive to topical steroids and etretinate treated successfully with 5 mg/kg daily ciclosporin that was slowly tapered. No recurrence of the disease was noted at 18 months.

Infliximab in the treatment of an HIV positive patient with Reiter's syndrome

Gaylis N. J Rheumatol 2003; 30: 2.

A case report of a 41-year-old man with ReA who responded to infliximab, methotrexate, and systemic corticosteroid treatment regimens. During therapy his arthritis resolved, as did the onycholysis and keratoderma blennorrhagica of the soles. The patient was able to discontinue systemic corticosteroids and was maintained on intravenous infliximab at a dose of 300 mg (3 mg/kg) every 6 to 7 weeks and intramuscular methotrexate at a dose of 15 mg/week for 18 months without a decrease in his CD4 cells or a rise in his viral load.

Decreased pain and synovial inflammation after etanercept therapy in patients with reactive and undifferentiated arthritis: an open-label trial

Flagg S, Meador R, Schumacher HR. Arthritis Rheum 2005; 53: 613–7.

Describes a 6-month open-label trial of 16 patients with undifferentiated or reactive arthritis treated with etanercept (25 mg subcutaneous twice weekly). Seven patients met the criteria for ReA, and 9 had a similar pattern of arthritis without evidence for infection. Ten patients completed the trial. Three patients tested positive for HLA-B27. All patients had been on NSAIDs, and 11 had been treated with sulfasalazine and/or methotrexate. Of the 10 completers, 9 were classified as responders with less tender joints and decreased swelling of joints. The tenth had improvement in pain but no change in the number of tender or swollen joints.

Successful use of infliximab in the treatment of Reiter's syndrome: a case report and discussion

Gill H, Majithia V. Clin Rheumatol 2008; 27: 121–3.

A case report of a 28-year-old man with HIV with ReA complicated by circinate balanitis and arthritis, as well as onycholysis and keratoderma blennorrhagica who did not respond to aggressive treatment with NSAIDs, prednisone (60–20 mg/day), and methotrexate (15 mg/week) for 3 months. He was treated with infliximab 200 mg (3 mg/kg) intravenously with rapid improvement

of skin lesions and arthritis. This regimen was well tolerated. The patient was subsequently lost to follow-up.

Use of adalimumab in poststreptococcal reactive arthritis

Sanchez-Cano D, Callejas-Rubio JL, Ortego-Centeno N. J Clin Rheum 2007; 13: 176.

A case report describing a 21-year-old female with oligoarthritis affecting the lower extremities after pharyngitis 2 weeks before the onset of arthritis. NSAIDs, prednisone (1 mg/kg/day), hydroxychloroquine (6 mg/kg/day), and methotrexate (25 mg/weekly) were not effective. Clinical response was achieved 8 weeks after introduction of adalimumab (40 mg subcutaneously every 2 weeks) and was maintained. Steroids and methotrexate were discontinued; no side effects were observed after 1 year of treatment with adalimumab.

The use of antitumor necrosis factor therapy in HIV-positive individuals with rheumatic disease

Cepeda E, William F, Ishimori M, Weisman M, Reveille J. Ann Rheum Dis 2008; 67: 710–2.

Eight HIV-positive patients with rheumatic diseases (two with rheumatoid arthritis, three with psoriatic arthritis, one with ReA, one with undifferentiated spondyloarthritis, and one with ankylosing spondyloarthritis) refractory to disease-modifying antirheumatic drugs who have a CD4 count $>200 \text{ mm}^3$ and an HIV viral load of $<60,000 \text{ copies/mm}^3$ and no active concurrent infections were treated with TNF blockers. No significant clinical adverse effect was noted over 28 months. CD4 counts and HIV viral loads remained stable. Three patients on etanercept and two on infliximab had sustained improvement in their rheumatic disease.

Prolonged remission of chronic reactive arthritis treated with three infusions of infliximab

Wechalekar M, Rischmueller M, Whittle S, Burnet S, Hill C. J Clin Rheumatol 2010; 16: 79–80.

A case report of a 25-year-old female with an 11-month history of progressive oligoarthritis and increasing CRP after *Chlamydia trachomatis* infection. She failed treatment with azithromycin, NSAIDs, corticosteroid injections, methotrexate, sulfasalazine, and hydroxychloroquine. Subsequently, infliximab at a dose of 6 mg/kg

was given. After the first two doses her symptoms resolved with normalization of her CRP. Methotrexate, sulfasalazine, and hydroxychloroquine were tapered without evidence of recurrent disease.

Safety and efficacy of antitumor necrosis factor α therapy in ten patients with recent-onset refractory reactive arthritis

Meyer A, Chatelus E, Wendling D, Berthelot JM, Dernis E, Houvenagel E, et al. *Arthritis Rheum* 2011; 63: 1274–80.

A retrospective review of anti-TNF- α therapy in 10 patients with evidence of new-onset ReA. Five patients were given infliximab (4 received 5 mg/kg and 1 received 3 mg/kg), 4 etanercept (50 mg/week), and 1 adalimumab (40 mg every 2 weeks). Concomitant therapies included NSAIDs (7 patients), oral corticosteroids (8 patients), methotrexate (7 patients), and sulfasalazine (3 patients). No severe adverse events were reported during the median 20.6 months. Nine of 10 patients had improvement in their rheumatic symptoms with a median of 15 days for >30% improvement in their pain score and tender joint count, and a median of 33 days for >30% improvement in their swollen joint count. Improvement of anterior uveitis (in 5 patients after 6 months) and cutaneous manifestations were also noted.

Spectacular evolution of reactive arthritis after early treatment with infliximab

Thomas-Pohl M, Tissot A, Banal F, Lechevalier D. *Joint Bone Spine* 2012; 79: 524.

A case report describing a 32-year-old male with acute febrile polyarthritis 1 month after gastrointestinal infection. After failing NSAIDs, ofloxacin (200 mg twice daily for 16 days), rifampin (300 mg twice daily for 4 days), and methylprednisone, he was given infliximab (5 mg/kg). Immediately after the infusion, he reported a decrease in pain with improvement of inflammatory markers.

Antibiotics

Antibiotics for treatment of reactive arthritis: a systematic review and meta-analysis

Barber CE, Kim J, Inman RD, Esdalle JM, James MT. *J Rheumatol*

2013; 40: 916–28.

A meta-analysis of 10 out of 12 eligible trials. There was no significant benefit comparing antibiotic use and disease remission. The authors also report substantial heterogeneity in the results and attributed this to differences in study design. Ultimately, the efficacy of antibiotics remains uncertain.

Combination antibiotics as a treatment for chronic *Chlamydia*-induced reactive arthritis: a double-blind, placebo controlled, prospective trial

Carter JD, Espinoza LR, Inman RD, Sneed KB, Ricca LR, Vasey FB, et al. *Arthritis Rheum* 2010; 62: 1298–307.

A prospective randomized trial with 42 patients who had evidence of chronic postchlamydial reactive arthritis. Patients were randomized to receive either doxycycline and rifampin (12 patients), azithromycin and rifampin (15 patients), or matching oral placebos (15 patients) for 6 months; 22% of subjects on combination antibiotic therapy achieved complete resolution of their symptoms in comparison to 0% of those receiving placebo. An increased number of patients in the antibiotic group became PCR negative for *Chlamydia* compared with the placebo group.

Regional pain and complex regional pain

David Rosenfeld, and Kristen Heins Fernandez

Complex Regional Pain Syndrome

Complex regional pain syndrome (CRPS) is a disorder characterized by spontaneous pain and signs of sympathetic dysfunction localized to a specific body region, often the distal limbs. It typically begins after trauma, such as a fracture, soft tissue injury, or surgery, and the associated pain is usually disproportionate to the expected course of injury. Although the pain in CRPS is regional, it does not tend to follow a specific dermatome or nerve territory. In addition to pain, if untreated, patients will suffer from swelling, limited range of motion, patchy bone demineralization, and skin changes.

CRPS is often referred to by its older alternative names, including reflex sympathetic dystrophy and causalgia. Currently, two subtypes of CRPS have been recognized: type I and type II. Type I (formerly reflex sympathetic dystrophy) refers to patients with CRPS who lack evidence of peripheral nerve injury. This occurs in 90% of clinical presentations. Type II (formerly causalgia) refers to cases in which evidence of peripheral nerve injury is present. Currently, the pathophysiology of CRPS is unclear, but there appears to be involvement of both proinflammatory cytokines and the sympathetic nervous system.

CRPS typically presents in three stages. Acutely, it begins with throbbing or burning pain and is associated with localized edema. During this phase, bone demineralization can occur. Stage two begins

a few months later, when the disease progresses to soft tissue damage, and is characterized by brawny, thickened skin and muscle wasting. Finally, the third, or atrophic, phase involves ridged nails, atrophic skin changes, and limitations of movement.

Early management of CRPS is critical, and therefore identification during the first stage is extremely important. Early diagnosis, however, can be quite challenging as the localized edema is often mistaken for other skin conditions. As a result, dermatologists can play a crucial role in its diagnosis and management.

Management Strategy

Managing CRPS is dependent on an accurate and timely diagnosis, which is based upon clinical features, history, and physical examination. Symptoms tend to affect a distal limb, and the patient will describe a history of trauma. The majority of patients will complain of impairment in motor function, which may involve paresis and clumsiness. Muscle spasms can be seen, often in patients with longer durations of CRPS type I. These can present as tremor, myoclonus, or dystonic postures. About 70% of patients will describe hypoesthesia, most frequently in a stockinglike or glovelike distribution. Other dysesthetic symptoms include allodynia (pain to touch), hyperpathia (exaggerated response to painful stimuli), and anesthesia dolorosa, when an area has lost its sensitivity to touch but demonstrates severe pain. Physical examination findings, particularly in the earlier stages, include edema, which is secondary to autonomic dysfunction. Atrophy and skin discoloration can occur during the later phases, along with atrophy of the soft tissues, bones, and muscles. Another hallmark of CRPS is altered skin temperature, which is a reflection of vasomotor instability. Many investigators have recognized “warm” and “cold” subtypes of CRPS, with the warm subtype being more associated with an inflammatory etiology. Later-stage disease may present with a limited range of motion. This is a result of a variety of skin and connective tissue changes, including increased hair growth, changes in nail growth, skin atrophy, and contraction and fibrosis of joints and fascia.

The diagnosis of CRPS is a clinical one based on the Budapest consensus criteria. First, the patient must have continuing pain that is disproportionate to the inciting event. The patient must also have at least one *sign* in two or more of the categories, as well as report at

least one *symptom* in three or more of the categories. Lastly, no other diagnosis should better explain the signs and symptoms. The categories of signs and symptoms are as follows:

Sensory –

- allodynia

- hyperesthesia

Vasomotor –

- temperature asymmetry ($>1^{\circ}\text{C}$)

- skin color changes

- skin color asymmetry

Sudomotor/edema –

- edema

- sweating changes and/or sweating asymmetry

Motor/trophic –

- decreased range of motion

- motor dysfunction (weakness, tremor, dystonia)

- trophic changes (hair, nail, skin)

On initial presentation, it is important to rule out several other conditions that may mirror CRPS. The differential diagnoses include infection, compartment syndrome, peripheral vascular disease, peripheral neuropathy, rheumatoid arthritis, deep vein thrombosis, Raynaud phenomenon, vascular thoracic outlet syndrome, conversion disorder, and factitious disorder.

Based on the presenting symptoms, it is reasonable to suspect an inflammatory arthropathy or vasculitis. Therefore blood work (complete blood count [CBC], erythrocyte sedimentation rate [ESR], C-reactive protein) and bone scan should be considered. Nerve conduction studies and electromyography (EMG) may be helpful in determining nerve damage, as seen in diabetes or nerve root avulsions. These can also be used to distinguish between CRPS type I and II, as in type II, EMG will confirm the presence of nerve injury, whereas in type I, nerve conduction studies will be normal.

Currently, the best treatment for CRPS is prevention. After a fracture or surgery, *vitamin C* supplementation has been shown to reduce the risk of developing CRPS. Early mobilization may also reduce the risk. When it comes to management of CRPS, earlier therapy results in better outcomes. First-line treatment involves physical and occupational therapy with adjuvant pharmacologic pain management, including *nonsteroidal antiinflammatory drugs (NSAIDs)*, *anticonvulsants*, and *topical anesthetics*. The efficacies of a pain

management specialist are largely unknown, although referral is a reasonable option. Second-line treatment involves interventional therapies, including *sympathetic nerve blockade and spinal cord stimulation*. The evidence for these in reducing pain in CRPS patients is currently unsupported, although many physicians anecdotally support them. Early interventional nerve blocks may help reduce pain, allowing patients to complete more rigorous physical therapy and therefore allowing for more rapid improvement.

Specific Investigations

- Plain radiography
- Bone scans
- Bone densitometry
- Thermography
- Sympathetic blocks
- CBC, ESR, C-reactive protein when vasculitis or arthritis suspected

Several investigations have been shown to be complementary to the clinical diagnostic criteria for CRPS. They can also help to objectively identify abnormal characteristics of the disease. Plain radiography can monitor significant changes over time, especially if normal at baseline. Patchy osteoporosis and periarticular osteopenia is often seen in plain radiographs as early as 2 weeks after onset of symptoms. Bone scans are extremely sensitive, although nonspecific, and can often detect osseous changes before plain radiography. Findings characteristic of CRPS include increased periarticular uptake in the third phase and vasomotor instability and abnormal patterns of flow distribution. As disease duration progresses, studies have shown the sensitivity of bone scans decreases, whereas specificity increases.

Bone densitometry is a useful tool in assessing efficacy of CRPS treatment. Densitometry will often reveal lowered bone mineral density early in the disease course, but as therapy progresses, density should improve. Thermography can be helpful in the diagnostic phase and allows the measurement of several symmetric points on the affected and contralateral extremity. Temperature differences can allude to the extent of CRPS—a difference in 0.5°C is considered mildly asymmetric, whereas a difference of 1.0°C is considered significant.

When determining treatment options for patients with CRPS, it is important to establish whether or not their pain is sympathetically dependent or independent. Sympathetically maintained pain (SMP) will respond favorably to an IV injection of phentolamine, resulting in transient pain relief. This is in contrast to patients with sympathetically independent pain (SIP), in which pain is not resolved by nerve blockade. Another option besides phentolamine is the use of local anesthetics—cervicothoracic blocks for upper extremity symptoms and lumbar paravertebral blocks for lower extremity symptoms. Results of sympathetic blockade help to guide further therapy.

Prevention

Can vitamin C prevent complex regional pain syndrome in patients with wrist fractures?

Zollinger PE, Tuinebreijer WE, Breederveld RS, Kreis RW. J Bone Joint Surg Am 2007; 89: 1424.

In a meta-analysis of 416 older women with risk fractures, CRPS was less prevalent in those who received vitamin C vs. placebo (any dose versus placebo, 2.4% versus 10.1%). Some women in the study received 200, 500, and 1500 mg of vitamin C, and the higher doses (500 and 1500 mg/day) had greater mean reductions in the relative risk of CRPS than did the lower dose (RR of 0.13, 0.17, and 0.41, respectively).

First-Line Therapies

• Anticonvulsant	A
• Physical and occupational therapy	B
• NSAID	B
• Bisphosphonate	B
• Tricyclic antidepressant	B
• Topical local anesthetic	E

The primary goal of therapy is to reduce pain and increase limb mobility and function. If treatment in these areas is successful, associated abnormalities will often improve. Physical therapy helps reduce edema and decrease guarding. It will also assist in improving daily activities. Physical therapy includes a range of active and passive movement exercise, as well as bandaging and desensitization techniques. Stress loading and functional therapy are important to help regain range of motion and dexterity. Early on, physical therapy may be required as often as three to five times a week. These activities and requirements vary from patient to patient. If a dermatologist is consulted on a diagnosis of CRPS, it is important to make quick referrals to physical and occupational therapy. Ultimately, a multidisciplinary approach is required, including patient education and addressing psychosocial contributing factors. In addition to these therapies, pharmacologic pain management is recommended for adjuvant treatment. Pain relief is an important part in allowing patients to adequately complete the necessary physical therapy, and therefore, analgesics such as NSAIDs and topical local anesthetics are recommended.

Physiotherapy for pain and disability in adults with complex regional pain syndrome (CRPS) types I and II

Smart KM, Wand BM, O'Connell NE. Cochrane Database Syst Rev 2016; 2: CD010853.

Some newer therapies involve graded motor imagery and mirrors

—these help to reduce the pain of CRPS and consist of imagined movement and mirror movement phases over a 6-week period. The best available data show that mirror therapy may provide meaningful improvements in pain and function in people with CRPS (type I), although the quality of supporting evidence is currently low.

Evidence based guidelines for complex regional pain syndrome type 1

Perez RS, Zollinger PE, Dijkstra PU, Thomassen-Hilgersom IL, Zuurmond WW, Rosenbrand KC, et al; CRPS I Task Force. BMC Neurol 2010; 10: 20.

NSAIDs are a great adjuvant treatment to physical therapy, although they are not well studied for CRPS. A typical regimen may include ibuprofen 400 to 800 mg three times a day or naproxen 240 to 500 mg twice daily. Antidepressants, particularly tricyclic antidepressants, have also been shown to reduce pain and are a valuable addition to physical therapy.

Randomised controlled trial of gabapentin in complex regional pain syndrome type 1

van de Vusse AC, Stomp-van den Berg SG, Kessels AH, Weber WE. BMC Neurol 2004; 4: 13.

Anticonvulsants such as gabapentin may also be beneficial for patients with CRPS, particularly if it is related to neuropathic pain. However, its efficacy in CRPS is currently not proven. In a randomized trial of 58 patients with CRPS, gabapentin produced no significant improvement in pain. However, clinical experience by physicians suggests that gabapentin and pregabalin may actually be helpful.

Bisphosphonate therapy of reflex sympathetic dystrophy syndrome

Adami S, Fossaluzza V, Gatti D, Fracassi E, Braga V. Ann Rheum Dis 1997; 56: 201.

Bisphosphonates have been shown to produce consistent and rapid remission of CRPS. In a study of 82 subjects with CRPS of the hand or foot who had disease duration of 4 months or less *and* abnormal uptake in bone scan, there was a significant decrease in visual analog pain scale for those in the neridronate group in comparison to the placebo group (−47 mm vs. −22.6 mm). There were no significant

adverse events reported.

Early adjunct treatment with topical lidocaine results in improved pain and function in a patient with complex regional pain syndrome

Hanlan AK, Mah-Jones D, Mills PB. Pain Physician 2014; 17: E629–35.

Topical 5% lidocaine ointment is a great noninvasive, inexpensive, and effective adjuvant therapy to CRPS treatment. Topical lidocaine is valuable in early CRPS and has been shown to reduce severe allodynia, allowing patients to participate more readily in rehabilitation strategies.

Second-Line Therapies

• Sympathectomy	A
• Glucocorticoids	B
• Sympathetic nerve block	B
• Spinal cord stimulation	B

Glucocorticoids are considered a viable option only if previous pharmacologic therapies have failed. In addition, interventional procedures may also be considered, including regional sympathetic nerve block, spinal cord stimulation, and sympathectomy. Although their efficacies are still unclear, many physicians recommend increasingly invasive interventions, particularly in patients receiving noninvasive therapy without improvement. The effectiveness of sympathetic nerve block in particular is dependent on whether or not the patient was responsive to diagnostic sympathetic blockade. When starting interventional therapy, it is generally recommended to allow 2 weeks for improvement before progressing to another form of treatment. Many care centers consider spinal cord stimulation the

most invasive therapy, and therefore, it should only be considered 12 to 16 weeks from the start of CRPS treatment.

Comparison of prednisolone with piroxicam in complex regional pain syndrome following stroke: a randomized controlled trial

Kalita J, Vajpayee A, Misra UK. QJM 2006; 99: 89.

In a study of patients with CRPS poststroke, corticosteroids were shown to be more effective than NSAIDs. The mean change in CRPS pain score in the prednisolone group was 6.47 compared with 0.47 in the piroxicam group. However, it is recommended to use NSAIDs and use glucocorticoids only when patients are unresponsive to other medications.

Local anaesthetic sympathetic blockade for complex regional pain syndrome

Stanton TR, Wand BM, Carr DB, Birklein F, Wasner GL, O'Connell NE. Cochrane Database Syst Rev 2013; 8: CD004598.

In an analysis of 12 studies, including 386 patients, most of them found no difference in pain outcomes between sympathetic block and other active treatments. The current evidence on the efficacy and safety of local anesthetics is very limited, but thus far, the data do not suggest that local anesthetics are effective in reducing pain in CRPS.

Spinal cord stimulation in patients with chronic reflex sympathetic dystrophy

Kemler MA, Barendse GA, van Kleef M, de Vet HC, Rijks CP, Furnée CA, et al. N Engl J Med 2000; 343: 618.

Spinal cord stimulation may be considered when other treatment modalities have failed. In a study of 36 patients with CRPS, 24 received implanted spinal cord stimulators plus physical therapy, whereas the remaining 12 patients received physical therapy only. The intensity of pain was measured on a visual analog scale from 0 cm (no pain) to 10 cm (very severe pain). In the group that received spinal cord stimulation, there was a mean reduction of 2.4 cm in the intensity of pain at 6 months compared with an increase of 0.2 cm in the group that received physical therapy only. It is reasonable to conclude that in patients with chronic CRPS, electrical spinal cord stimulation can reduce pain and improve quality of life.

Cervico-thoracic or lumbar sympathectomy for neuropathic pain

and complex regional pain syndrome

Straube S, Derry S, Moore RA, Cole P. Cochrane Database Syst Rev 2013; 9: CD002918.

The only study that met their criteria was one that compared lumbar sympathectomy with lumbar sympathetic neurolysis with phenol in 20 participants with CRPS. There was no comparison of sympathectomy versus sham or placebo. There was no significant difference in pain scoring between the two groups initially and over 4 months. However, patients who received radiofrequency ablation sympathectomy complained of an “unpleasant sensation.”

Sympathectomy should only be considered in patients with a positive pain response to diagnostic sympathetic blockade and when all other treatment modalities have failed. Patients must also be informed of the high rates of adverse effects, including increased pain, new neuropathic pain, and bothersome sweating.

Relapsing polychondritis

David P. D'Cruz

Relapsing polychondritis is an autoimmune rheumatic disorder characterized by cartilage inflammation. Characteristic features

include nasal bridge, auricular and ocular inflammation, and major airway disease. It is rare with an incidence of 0.71/million/year, with an increased mortality rate, and there is often a delay in establishing a diagnosis.

The diagnosis is established by the presence of chondritis in two of three characteristic anatomic sites: auricular, nasal, laryngotracheal, or one of these sites and two other features, including ocular inflammation, audiovestibular damage, or seronegative inflammatory arthritis. In most patients, histologic confirmation is not necessary for diagnosis.

Auricular chondritis manifests as ear pain, redness, and swelling with sparing of the noncartilaginous lobule. After repeated relapses, the pinnae may be floppy and distorted or have a cauliflower-like appearance. The ear may become rigid after extensive calcification. Recurrent nasal chondritis results in a saddle-nose deformity.

Skin manifestations include oral ulceration, sometimes with genital ulceration, nodules, purpura, papules, sterile pustules, superficial phlebitis, livedo reticularis, skin ulcers, and distal necrosis.

Laryngeal chondritis presents with hoarseness, tracheal ring tenderness, cough, breathlessness, and stridor. All patients with suspected pulmonary disease should undergo computed tomography (CT) imaging, including end-inspiratory and dynamic expiratory volumetric imaging. End-inspiratory scanning may reveal tracheal and bronchial stenosis, wall thickening, and calcification. Expiratory scans may demonstrate tracheobronchial malacia with airway collapse and air trapping.

Cardiovascular complications eventually occur in half of all patients and are the second most frequent cause of mortality. Aortic valve inflammation, the most common cardiac manifestation (10% of patients), may occur in asymptomatic patients and can silently progress during seemingly effective systemic corticosteroid therapy. Atrioventricular block, mitral regurgitation, and acute pericarditis may also occur.

Central and peripheral nerve involvement is rare. Cranial nerve lesions are the most common, but other complications include seizures, cerebral dysfunction, confusion, headaches, cerebral aneurysm, and rhomboencephalitis.

All patients should be monitored for the development of renal disease with routine urine dip testing for blood and protein.

Disease activity is assessed clinically by standard methods. There is

an objective scoring system, the Relapsing Polychondritis Disease Activity Index (RPDAI), that provides objective disease assessment for use in clinical studies.

Otologic manifestations of relapsing polychondritis. Review of literature and report of nine cases

Bachor E, Blevins NH, Karmody C, Kühnel T. *Auris Nasus Larynx* 2006; 33: 135–41.

A good description of the broad spectrum of ear manifestations. No patients died, suggesting patients with limited disease have a good prognosis.

Up to 46% of patients have impaired hearing, and inadequately treated patients can suffer permanent hearing loss. Screening audiometry is highlighted. Ocular, neurologic, and renal disease can also occur in relapsing polychondritis. Cardiac manifestations include aortic regurgitation, aortic aneurysm, atrioventricular block, mitral regurgitation, and acute pericarditis, making periodic cardiac examination mandatory.

Relapsing polychondritis: prevalence of expiratory CT airway abnormalities

Lee KS, Ernst A, Trentham DE, Lunn W, Feller-Kopman DJ, Boiselle PM. *Radiology* 2006; 240: 565–73.

Dynamic expiratory CT scans demonstrated abnormalities such as tracheomalacia and air trapping in 94% of relapsing polychondritis patients who had pulmonary symptoms, yet only half the patients demonstrated abnormalities on routine inspiratory CT scans. The most common findings were air trapping (94%), malacia (72%), and calcification (39%).

Expiratory CT scans show clinically relevant bronchopulmonary abnormalities earlier than standard inspiratory CT scans, allowing earlier institution of aggressive therapy to prevent disease progression.

Airway manifestations are ultimately present in over 50% of patients and are the leading cause of death. Airway obstruction may be asymptomatic in the earlier stages, detected only on pulmonary function testing. Other sources stress the importance of plain radiography, CT, and Magnetic resonance imaging (MRI) for early detection of tracheal narrowing and upper airway disease.

Dermatologic manifestations of relapsing polychondritis. A study of 200 cases at a single center

Francés C, el Rassi R, Laporte JL, Rybojad M, Papo T, Piette JC. *Medicine (Baltimore)* 2001; 80: 173–9.

Cutaneous manifestations of patients with relapsing polychondritis: an association with extracutaneous complications

Shimizu J, Oka H, Yamano Y, Yudoh K, Suzuki N. *Clin Rheumatol* 2016; 35: 781–3.

Two of the largest series in the literature of >200 patients described a variety of skin manifestations, including oral ulceration sometimes with genital ulceration, nodules, purpura, papules, sterile pustules, superficial phlebitis, livedo reticularis, neutrophilic dermatoses including Sweet syndrome, skin ulcers, and distal necrosis. In Francés et al.'s paper, oral ulceration was the most common finding in patients with relapsing polychondritis who did not have any other disease, and in seven patients genital ulcers were also seen. The acronym MAGIC (mouth and genital ulceration with inflamed cartilage) has previously been coined to describe patients who appear to have relapsing polychondritis with oral and genital ulceration. However, this syndrome is controversial, and these patients are more likely to be an overlap of Behçet disease with relapsing polychondritis, especially as relapsing polychondritis may occur in association with other autoimmune rheumatic diseases.

Nodules on the limbs were the most common skin lesions and have been described as erythema nodosum–like lesions with septal panniculitis. Histologic findings included vasculitis in 19 patients (leukocytoclastic in 17 and lymphocytic in 2), neutrophil infiltrates in 6, thrombosis of skin vessels in 4, septal panniculitis in 3, and minor nonspecific changes in 2 patients. Both these studies described patients with myelodysplastic syndromes and relapsing polychondritis, and these patients were much more likely to have dermatologic manifestations, most commonly limb nodules, purpura, papules, and livedo reticularis, as well as neutrophilic dermatoses including Sweet syndrome. They recommend that elderly patients with relapsing polychondritis and skin lesions be investigated for an underlying myelodysplastic syndrome. This confirmed previous data from Hebbar et al. from 1995 (see next).

Association of myelodysplastic syndrome and relapsing polychondritis: further evidence

Hebbar M, Brouillard M, Wattel E, Decoulx M, Hatron PY, Devulder B, et al. *Leukemia* 1995; 9: 731–3.

Twenty-eight percent (5 of 18) of relapsing polychondritis patients over a period of 13 years were found to have myelodysplastic syndromes.

Anemia is a poor prognostic sign in patients with relapsing polychondritis; those with concurrent myelodysplasia often develop refractory anemia requiring transfusions. Several patients have progressed to leukemia.

Management Strategy

Treatment of relapsing polychondritis is aimed at reducing inflammation, which may progressively destroy the ears, nose, eyes, joints, respiratory tract, and cardiovascular system. The most common cause of mortality is laryngotracheal involvement. A multidisciplinary approach, including referral to specialist centers, is crucial to evaluate and treat multiple organ involvement. There are no controlled trials: treatment is empiric and should be tailored to the severity of disease.

Mildly affected patients may be managed using *nonsteroidal antiinflammatory agents*. They should be used sparingly and for short periods given the long-term risks of gastrointestinal, renal, and cardiovascular complications. *Colchicine* 0.5 mg twice daily and *dapsone* 50 to 100 mg daily have also provided benefit, but toxicity may occur, especially with dapsone and G6PD (glucose-6-phosphate dehydrogenase) deficiency.

Corticosteroids are widely used for more severe disease. Life-threatening airway obstruction may be treated with pulsed intravenous methylprednisolone (500 mg to 1 g/day for 3 days). The traditional dose of 1 mg/kg/day is completely non-evidence based, is excessive, and should be abandoned. High-dose corticosteroids contribute significantly to long-term damage, which is associated with premature mortality. Most patients with moderate disease will benefit from doses of prednisolone between 10 and 20 mg daily in a tapering dose irrespective of body weight. The lowest possible maintenance dose should be used, and some patients may be able to use intermittent short courses of prednisolone 20 mg daily for 1 to 2 weeks. Bone prophylaxis with calcium and vitamin D supplementation should be considered in corticosteroid-dependent

patients.

Second-line therapies should be considered for patients unable to taper corticosteroid doses. The most commonly used agents are methotrexate (considered first line by most experts) 5 to 25 mg weekly, azathioprine 1.5–2 mg/kg/day, ciclosporin 5 mg/kg/day, mycophenolate mofetil 2 to 3 g/day, leflunomide, and chlorambucil. Intravenous cyclophosphamide has been used for severe rapidly progressive and life-threatening disease, especially for aortitis or glomerulonephritis. Plasma exchange and intravenous immunoglobulin (IVIG) therapy are usually not successful, but isolated case reports have described clinical benefit.

Biologic agents are increasingly being used off label for treatment-resistant patients with some success. Infliximab, adalimumab, etanercept, tocilizumab, and anakinra have all been reported to improve disease control in isolated case reports.

Topical steroids may be used to treat skin manifestations and are standard therapy for ocular inflammation. Inhaled steroids may be useful in mild airway inflammation, and nebulized epinephrine has been used occasionally.

Respiratory support with continuous positive airway pressure and other noninvasive ventilation devices may improve quality of life for patients where surgical intervention or stenting is not feasible.

Surgical intervention may be needed acutely when tracheostomy is needed for tracheal stenosis. Other surgical interventions to manage fibrotic or stenotic complications should only be considered electively when the disease is in remission. Tracheal surgery, including reconstruction procedures, may be needed for localized stenosis. Balloon dilatation may be used either alone or in combination with other surgical procedures. Large airway stenting has been successfully used, although metallic stents, usually used for malignant disease, may erode the airways over time. Silicon stents are more likely to migrate or be expectorated. Endobronchial ultrasound has been used to identify localized stenotic lesions and to measure airway size before positioning of stents.

Cardiac valve replacement and aortic surgery are associated with significant surgical morbidity and mortality, but several case reports describe successful outcomes. Any general anesthetic that requires intubation and ventilation before surgery requires careful preoperative anesthetic review.

Specific Investigations

- Otolaryngologic evaluation
- Audiometry
- Pulmonary evaluation
- Chest radiograph and/or CT/MRI
- Dynamic expiratory CT examination
- Pulmonary function tests (especially flow/volume loops)
- Endobronchial ultrasonography
- Cardiovascular examination
- Electrocardiogram and/or echocardiogram (CT/MRI may also be useful)
- Ophthalmologic examination
- Urinalysis

First-Line Therapies

• NSAIDs	D
• Colchicine	C
• Dapsone	C
• Systemic corticosteroids	C

Treatment of relapsing polychondritis with dapsone

Barranco VP, Monor DB, Solomon H. Arch Dermatol 1976; 112: 1268–88.

Three patients were successfully treated with dapsone (100–200 mg daily), each showing complete resolution of an acute attack of relapsing polychondritis within 2 weeks of starting therapy.

Although not all patients respond to dapsone, those who do may improve dramatically within 1 to 2 weeks. The effectiveness of dapsone seems to be

dose dependent, with 200 mg daily being the most commonly reported effective dose. G6PD levels should be measured before treatment to avoid the risk of dapsone-induced hemolytic anemia.

Relapsing polychondritis

Kent PD, Michet CJ Jr, Luthra HS. Curr Opin Rheumatol 2004; 16: 56–61.

A well-written and comprehensive review of the clinical features, assessment, and management of relapsing polychondritis. Recommendations for corticosteroid doses are given ranging from 10 to 20 mg daily of prednisolone for mild to moderate disease up to high-dose prednisolone and intravenous methylprednisolone 500 mg to 1 g/day for 3 days.

Second-Line Therapies

• Azathioprine	D
• Ciclosporin	D
• Methotrexate	D
• Mycophenolate mofetil	D
• Leflunomide	D
• Cyclophosphamide	E
• Intravenous immunoglobulin	E
• Infliximab	D
• Adalimumab	E
• Etanercept	E
• Inhaled fluticasone	E
• Continuous positive airway pressure	E
• Tracheobronchial stents	E

Relapsing polychondritis

Trentham DE, Le CH. Ann Intern Med 1998; 129: 114–22.

In this review, 23 of 31 patients were able to reduce their prednisone dose from an average of 19 mg daily to 5 mg daily by adding methotrexate (average weekly methotrexate dose 15.5 mg).

A good review article.

Relapsing polychondritis: a clinical update

Longo L, Greco A, Rea A, Lo Vasco VR, De Virgilio A, De Vincentiis M. Autoimmun Rev 2016; 15: 539–43.

An excellent clinical review of relapsing polychondritis and its

treatment, covering the use of corticosteroids, immunosuppressive agents, and biologics in some depth.

Successful treatment of relapsing polychondritis with mycophenolate mofetil

Goldenberg G, Sanguenza OP, Jorizzo JL. J Dermatol Treat 2006; 17: 158–9.

A 50-year-old man with bilateral ear pain was successfully treated with a prednisone taper and mycophenolate 3 g/day (increased from an initial dose of 2 g/day). At 17 months' follow-up the patient maintained his improvement on prednisone 5 mg daily and mycophenolate 3 g/day.

Successful treatment of relapsing polychondritis with infliximab

Richez C, Dumoulin C, Coutoly X, Schaefferbeke T. Clin Exp Rheumatol 2004; 22: 629–31.

One patient had marked improvement in symptoms 4 days after an infusion of 4 mg/kg infliximab. Control was maintained with repeat treatments every 6 to 8 weeks.

Infliximab seems to be an effective therapy for relapsing polychondritis unresponsive to conventional therapy, as well as a steroid-sparing agent.

Sustained response to etanercept after failing infliximab, in a patient with relapsing polychondritis with tracheomalacia

Subrahmanyam P, Balakrishnan C, Dasgupta B. Scand J Rheumatol 2008; 37: 239–40.

A 54-year-old woman with relapsing polychondritis complicated by tracheomalacia experienced a dramatic improvement in her symptoms and an 18-month sustained response after etanercept was substituted for infliximab.

Prolonged response to antitumor necrosis factor treatment with adalimumab (Humira) in relapsing polychondritis complicated by aortitis

Seymour MW, Home DM, Williams RO, Allard SA. Rheumatology 2007; 46: 1739–41.

A 43-year-old woman who had undergone aortic valve replacement continued to experience aortitis despite a variety of immunosuppressive drugs and cytotoxic agents. Despite an initial good response to infliximab, after 10 months her symptoms returned.

Switching her anti-tumor necrosis factor (TNF) agent to adalimumab and continuing methotrexate and corticosteroids resulted in improvement; she has subsequently been maintained on adalimumab and low-dose corticosteroids.

These two reports suggest that switching anti-TNF agents may benefit patients with recalcitrant relapsing polychondritis.

Complete remission in refractory relapsing polychondritis with intravenous immunoglobulins

Terrier B, Aouba A, Bienvenu B, Bloch-Queyrat C, Delair E, Mallet J, et al. Clin Exp Rheumatol 2007; 25: 136–8.

A young woman with relapsing episodes of nasal chondritis and severe scleritis with scleromalacia received IVIG every 3 then every 4 weeks (2 g/kg on 2 days) in association with 25 mg/day of prednisone after treatment with corticosteroids, infliximab, methotrexate, mycophenolate, and cyclophosphamide failed to control her symptoms. Dramatic improvement of symptoms was sustained for 11 months, but when IVIG treatments were spaced every 6 weeks hearing loss and episcleritis recurred. Reinstitution treatment every fourth week brought her symptoms under control.

Use of inhaled fluticasone propionate to control respiratory manifestations of relapsing polychondritis

Tsuburai T, Suzuki M, Tsurikisawa N, Ono E, Oshikata C, Taniguchi M, et al. Respiriology 2009; 14: 299–301.

A 19-year-old patient with relapsing polychondritis used high-dose fluticasone propionate, which reduced oral corticosteroid requirements and dramatically decreased the patient's obstructive airway impairment.

Treatment of diffuse tracheomalacia secondary to relapsing polychondritis with continuous positive airway pressure

Adliff M, Ngato D, Keshavjee S, Brenaman S, Granton JT. Chest 1997; 112: 1701–4.

A patient with relapsing polychondritis of the trachea and bronchi was treated with nasal continuous positive airway pressure. This approach is now widely used.

Management of airway manifestations of relapsing polychondritis: case reports and review of the literature

Sarodia SD, Dasgupta A, Mehta AC. Chest 1999; 116: 1669–75.

Five patients with severe respiratory involvement (three of whom required continuous mechanical ventilation due to airway collapse) benefited from placement of self-expandable metallic tracheobronchial stents. A total of 17 stents of varying sizes were placed in these patients over a period of 3 years, with favorable outcomes in four patients.

When severe, progressive disease leads to extensive destruction of the tracheobronchial tree despite maximal medical therapy, and tracheostomy or tracheobronchial stent placement may preserve or improve respiratory function and reduce patients' reliance on mechanical ventilation.

Endobronchial ultrasonography in the diagnosis and treatment of relapsing polychondritis with tracheobronchial malacia

Miyazu Y, Miyazawa T, Kurimoto N, Iwamoto Y, Ishida A, Kanoh K, et al. Chest 2003; 124: 2393–5.

Endobronchial ultrasonography revealed poorly defined bronchial wall structure with two patterns of cartilaginous damage: fragmentation and edema. Successful treatment was achieved by the implantation of nitinol stents, the sizes of which were determined by endobronchial ultrasonography.

Surgical treatment of the cardiac manifestations of relapsing polychondritis: overview of 33 patients identified through literature review and the Mayo Clinic records

Dib C, Moustafa SE, Mookadam M, Zehr KJ, Michet CJ Jr, Mookadam F. Mayo Clin Proc 2006; 81: 772–6.

Clinically important aortic or mitral regurgitation occurs in about 10% of relapsing polychondritis patients, with aortic regurgitation being the more common and more urgent. In this retrospective series and literature review the mean time between initial onset of relapsing polychondritis and surgery was about 5 years. In contrast to previous reports of 70% 1-year mortality after valve replacement, in this analysis 50% of patients were alive 1 year after surgery.

Aortic regurgitation is a serious complication of relapsing polychondritis. Baseline chest CT, MRI, or transesophageal echocardiography should be performed upon diagnosis and repeated every 6 months. All aortic segments should be regularly evaluated because involvement of multiple thoracic and abdominal aneurysms has been reported in several patients.

Anesthesia in a patient with acute respiratory insufficiency due to relapsing polychondritis

Biro P, Rohling R, Schmid S, Matter C, Lang M. J Clin Anaesth 1994; 6: 59–62.

This case report highlights the need for careful preoperative evaluation of vital organ functions, with particular reference to airway management, so that the anesthetic approach can be tailored to the individual needs of the patient.

Relapsing polychondritis can be characterized by 3 different clinical phenotypes: analysis of a recent series of 142 patients

Dion J, Costedoat-Chalumeau N, Sène D, Cohen-Bittan J, Leroux G, Dion C, et al. Arthritis Rheumatol 2016; 68: 2992–3001.

This study used cluster analysis to define three groups that were clinically relevant in terms of prognosis: cluster 1, which had the highest mortality, included more men who were older at diagnosis, with myelodysplasia, general symptoms, and cutaneous and cardiac disease; cluster 2 had younger patients with predominant large airway disease; and cluster 3 had patients with mild disease and long-lasting remissions.

Rhinophyma

Surod Qazaz, and John Berth-Jones

Phymas, of which rhinophyma is the most common, are localized swellings of facial soft tissues due to a variable combination of fibrosis, sebaceous hyperplasia, and lymphedema. They occur on the nose (rhinophyma) and, less often, the ears, forehead, or chin. They are seen much more frequently in males than in females. Rhinophyma may develop in patients with a long history of rosacea, when it is often regarded as a complication or “end stage” of the disease. However, rhinophyma is also seen in patients who have no history of rosacea. Occasionally rhinophyma is complicated by the development

of a malignancy.

Management Strategy

Phymas require *physical ablation* or removal, usually by *surgery*. Remodeling is most often achieved simply by paring off the excess tissue with a scalpel. Other techniques that can be useful in the hands of those with the necessary expertise include electrosurgery, excision/vaporization with argon, CO₂, Nd:YAG or Er:YAG lasers, and cryotherapy. Ionizing radiation has been used in cases with coexisting malignancy. Systemic *isotretinoin* can significantly reduce the bulk of rhinophyma, although it does not restore normal skin contours. It is possible, but not established, that treatment of rosacea may inhibit the development of rhinophyma.

Specific Investigation

- Biopsy is occasionally indicated to exclude malignancy

Rhinophyma and coexisting occult skin cancers

Lutz ME, Otley CC. Dermatol Surg 2001; 27: 201–2.

Rhinophyma can be complicated by the development of a malignancy, which can be difficult to recognize.

Rhinophyma and nonmelanoma skin cancer: an update

Lazzeri D, Agostini T, Pantaloni M, Spinelli G. Ann Chir Plast Esthet 2012; 57: 183–4.

In addition to basal cell, squamous cell, and basosquamous carcinomas, rarely, angiosarcoma and sebaceous carcinoma may occur.

First-Line Therapy

- | | |
|-------------------|---|
| • Surgical paring | C |
|-------------------|---|

Triple approach to rhinophyma

Curnier A, Choudhary S. Ann Plast Surg 2002; 49: 211–4.

The authors report pleasing results in six patients treated by tangential excision for debulking, the use of scissors for sculpting, and mild dermabrasion for final contouring.

Second-Line Therapies

• Electrosurgery	C
• Argon laser	C
• CO ₂ laser	C
• Nd:YAG laser	E
• Er:YAG laser	D
• Cryotherapy	D
• Isotretinoin	C
• Microdebrider	E
• Shaw scalpel	E
• Radiotherapy	E
• Hydrosurgery	D

Electrosurgical treatment of rhinophyma

Clark DP, Hanke CW. J Am Acad Dermatol 1990; 22: 831–7.

This treatment was inexpensive and associated with few complications and gave good or excellent cosmetic results in 13 cases.

Surgical management of rhinophyma: report of eight patients treated with electrosection

Rex J, Ribera M, Bielsa I, Paradelo C, Ferrándiz C. Dermatol Surg 2002; 28: 347–9.

Eight male patients were treated using radiofrequency electrosurgery to remove thin layers of tissue until the nose shape was re-created. All patients achieved acceptable cosmetic results.

Rhinophyma treated by argon laser

Halsbergen-Henning JP, van Gemert MJ. Lasers Surg Med 1983; 2: 211–5.

Thirteen cases were treated. This laser is believed to work by selectively coagulating capillaries that cause redness of the nose and that feed the hypertrophic regions, as well as by directly causing coagulation shrinkage of the hypertrophic connective tissue. The result was a smooth and more natural appearance of the nose without redness. Pustulosis was also reduced.

Comparison of CO₂ laser and electrosurgery in the treatment of rhinophyma

Greenbaum SS, Krull EA, Watnick K. J Am Acad Dermatol 1988; 18: 363–8.

The results from the CO₂ laser and electrosurgery were compared in three patients by treating one side of the nose by each method. There was little to choose between them in terms of results, but electrosurgery was more cost effective.

Carbon dioxide laser treatment of rhinophyma: a review of 124 patients

Madan V, Ferguson JE, August PJ. Br J Dermatol 2009; 161: 814–8.

Exuberant sebaceous tissue was ablated using the Sharplan 40C CO₂ laser under local anesthesia. The laser was used in a continuous

mode to debulk the larger rhinophymas and in a resurfacing mode (Silk Touch scanner; Sharplan, 4–7 mm spot at 20–40 W) or continuous mode (10–20 W using a defocused 2–3-mm beam) to reshape the nasal contours. Results were classified as good to excellent in 118 and poor in 6 patients.

Spectrum of results after treatment of rhinophyma with the carbon dioxide laser

El Azhary RA, Roenigk RK, Wang TD. Mayo Clin Proc 1991; 66: 899–905.

A review of 30 patients treated with the CO₂ laser and followed up for 1 to 4 years. Milder cases were treated with laser vaporization, more severe cases with CO₂ laser excision and then vaporization. Dilated pores developed in many patients. Leukoderma, unilateral alar lift, and mild hypertrophic scarring developed in single cases.

Surgical correction of rhinophyma: comparison of two methods in a 15-year-long experience

Lazzeri D, Larcher L, Huemer GM, Riml S, Grassetti L, Pantaloni M, et al. J Craniomaxillofac Surg 2013; 41: 429–36.

Long-term results in 45 cases treated with tangential excision and 22 treated with the CO₂ laser. Minor complications, including scarring and hypopigmentation, were seen in six patients. All patients were satisfied with their outcomes at the follow-up visit, and no major complications were detected. The authors did not consider the extra cost of laser treatment to be justified.

Excision of rhinophyma with Nd:YAG laser: a new technique

Wenig BL, Weingarten RT. Laryngoscope 1993; 103: 101–6.

Treatment of rhinophyma with Er:YAG laser

Orenstein A, Haik J, Tamir J, Winkler E, Frand J, Zilinsky I, et al. Lasers Surg Med 2001; 29: 230–5.

Use of a dual-mode erbium:YAG laser for the surgical correction of rhinophyma

Fincher EF, Gladstone HB. Arch Facial Plast Surg 2004; 6: 267–71.

In each of these reports six cases of rhinophyma were treated with satisfactory outcomes. The Er:YAG laser provides both controlled

ablation of tissue and hemostasis.

Rhinophyma treated by liquid nitrogen spray cryosurgery

Sonnex TS, Dawber RPR. Clin Exp Dermatol 1986; 11: 284–8.

Five cases were treated using two freeze–thaw cycles, each freeze lasting 30 seconds after the ice field was established, with a 4-minute intervening thaw. A pethidine and diazepam premedication was used. In three cases small residual prominent areas responded to further treatment after 2 months. The final result was satisfactory in each case, with no scarring.

Isotretinoin in the treatment of rosacea and rhinophyma

Irvine C, Kumar P, Marks R. In: Marks R, Plewig G, eds. Acne and Related Disorders. London: Martin Dunitz, 1989; 311–5.

A study in which nine men with rhinophyma were treated with isotretinoin 1 mg/kg daily for up to 18 weeks. Isotretinoin reduced the volume of rhinophyma (assessed objectively using molds of the noses) by 9% to 23% but did not restore normal skin contours in advanced cases.

The authors report good results in five cases and consider this their treatment of choice.

New surgical adjuncts in the treatment of rhinophyma: the microdebrider and FloSeal

Kaushik V, Tahery J, Malik TH, Jones PH. J Laryngol Otol 2003; 117: 551–2.

This is a report of a single case treated using this approach. The microdebrider is a powered rotary shaving device. FloSeal is a hemostatic mixture of thrombin and gelatin applied topically after the surgery. The use of these adjuncts allowed precise sculpting and immediate hemostasis.

Surgical treatment of rhinophyma with the Shaw scalpel

Eisen RF, Katz AE, Bohigian RK, Grande DJ. Arch Dermatol 1986; 122: 307–9.

The Shaw scalpel is a device in which a scalpel blade can be heated. A rhinophyma was treated using a temperature of 150°C to achieve hemostasis while paring. Contours were then refined using a CO₂ laser and light dermabrasion.

Rhinophyma, associated with carcinoma, treated successfully with radiation

Plenk HP. *Plast Reconstruct Surg* 1995; 95: 559–62.

Two patients with basal cell carcinoma complicating rhinophyma had complete control of both conditions by radiotherapy using orthovoltage x-radiation. The authors suggest that this modality might be useful for rhinophyma alone.

Rhinophyma treated with kilovoltage photons

Skala M, Delaney G, Towell V, Vladica N. *Australas J Dermatol* 2005; 46: 88–9.

A rhinophyma was successfully treated with 90-kV photons to a total dose of 40 Gy in 20 daily fractions.

Treatment of rhinophyma with the Versajet Hydrosurgery System

Taghizadeh R, Mackay SP, Gilbert PM. *J Plast Reconstruct Aesthet Surg* 2008; 61: 330–3.

Six patients were treated successfully.

The Versajet Hydrosurgery System is a novel surgical device that uses a high-velocity jet of water for excision and vacuum aspiration of water and debris.

A new surgical technique of rhinophyma (gull-wing technique)

Karacor-Altuntas Z, Dadaci M, Ince B, Altuntas M. *J Craniofac Surg* 2015; 26: e28–30.

A severe rhinophyma underwent full-thickness excision using gull-wing elevation of the nasal tip and dorsal skin. The patient was very satisfied with the result.

Rocky Mountain spotted fever and other rickettsial infections

Amer Ali Almohssen, George G Kihiczak, and Robert A. Schwartz

The Rickettsiae are a family of obligate intracellular gram-negative bacteria that cause infections with a diverse array of clinical presentations. They are vectorborne diseases that may be divided into the spotted fevers (including Rocky Mountain spotted fever), the typhus group, rickettsialpox, Q fever, and ehrlichiosis.

Rickettsial Spotted Fevers

These infections include African tick bite fever (*Rickettsia africae*), Astrakhan fever (*R. conorii*), Flinders Island spotted fever (*R. honei*), Indian tick typhus (*R. conorii*), Israeli spotted fever (*R. conorii*), Japanese spotted fever (*R. japonica*), Mediterranean spotted fever (*R. conorii*), Queensland tick typhus (*R. australis*), Siberian tick typhus (*R. sibirica*), and Rocky Mountain spotted fever (*R. rickettsii*).

Rocky Mountain spotted fever (RMSF) is caused by *Rickettsia rickettsii* and is endemic to almost all areas of the United States with a high degree of prevalence in North Carolina, Tennessee, and Oklahoma. RMSF is transmitted by *Demacentor andersoni* in the western United States and by *D. variabilis* (pictured on the back of a patient in the figure above) in the eastern United States. The classic triad seen early in the course of the disease consists of a tick bite, rash, and fever. The characteristic rash is composed of pink macules that appear on the wrists and ankles; become petechial and purpuric; and then progress to the palms, soles, extremities, and trunk, sparing the face.

This macular rash does not appear until the third day after the onset of symptoms and is seen in more than 90% of cases. A petechial rash is usually not evident until the sixth day and only occurs in 35% to 60% of patients. Atypical rashes, confined to one region of the body, may be evident.

Fever, myalgias, and severe headaches are present in most cases, with bilateral calf pain being the most common presenting complaint. Gastrointestinal symptoms such as abdominal pain, diarrhea, nausea, and vomiting occur in nearly half of patients, usually early in the course of the illness. These findings often lead to a misdiagnosis or delay in therapy. Vascular injury to the small intestine, appendix, and gallbladder may occur, in some cases mimicking acute cholecystitis.

Prognosis is related to the timely diagnosis and initiation of effective treatment. Prevention is achieved by avoiding areas with ticks. Covering skin with long protective clothing reduces the risk of

exposure. Clothing may be impregnated with acaricidal compounds for added protection. Any uncovered skin should be treated with a topical insect repellent before activities in high-risk areas.

Unfortunately, most insect repellents are effective for only short periods and need to be reapplied frequently. Thorough skin examinations should be conducted on a regular basis, at least twice daily in endemic areas, and any ticks removed. The scalp, axillary, and pubic hair require particularly careful examination. There is currently no effective vaccine, although immunogenic surface protein antigens have been cloned and sequenced.

Management Strategy

Clinical suspicion of a spotted fever is sufficient to warrant treatment. Serologic confirmation should not delay the initiation of appropriate therapy. Diagnosis is difficult, as the characteristic rash is not a reliable sign of disease, and the classic triad of tick bite, rash, and fever is often not evident.

The spotted fevers progress rapidly and, therefore, immediate treatment is required, ideally in the first 3 to 4 days. Doxycycline is the best first-line agent for treating RMSF and other spotted fevers, as shown by extensive data and clinical experience. Doxycycline is administered at a dose of 100 mg twice daily orally in adults. Children under 45.4 kg should receive 2.2 mg/kg per dose twice daily orally. The therapeutic benefit provided by doxycycline in the treatment of RMSF is thought to outweigh the potential risk for tooth discoloration in children receiving doxycycline. These oral antibiotics are taken for a minimum of 7 days and are continued until the patient is afebrile for 72 hours. Within 24 hours of the initiation of treatment, a response may be observed. Within the first 48 hours considerable clinical improvement is seen; apyrexia is often achieved by 72 hours. In severe cases requiring hospitalization, intravenous doxycycline every 12 hours is the recommended treatment.

Tetracycline (500 mg every 6 hours, maximum dose 2 g) is efficacious, but is contraindicated in patients with renal failure, during pregnancy, and in children under 8 years of age.

Chloramphenicol (50–75 mg/kg daily, divided into four doses, for 7 days) is the recommended treatment for pregnant women. When using chloramphenicol, close monitoring is prudent due to the limited data on treatment as well as the increased risk of gray baby syndrome

in pregnant women and aplastic anemia in children.

Death occurs at a higher rate in those untreated beyond 5 days of illness onset. Of note, early discontinuation of therapy may result in relapse. RMSF has a case-fatality rate as high as 30% in certain untreated patients. Even with treatment, hospitalization rates of 72% and case fatality rates of 4% are seen.

Supportive care is also an important component in successful treatment. A high-protein diet, adequate hydration, and continuous monitoring of blood volume are critical. In cases in which renal, pulmonary, or cardiac complications occur, other specialized therapies may be required.

Specific Investigations

- Skin biopsy, direct immunofluorescence/immunoperoxidase
- Serologic testing for antirickettsial antibodies
- Polymerase chain reaction (PCR)

Diagnosis is most often based on clinical presentation, as patients may have a history of a tick bite after spending time in an endemic area. Clinical suspicion requires the rapid initiation of therapy even when confirmatory tests are pending, as mortality increases when treatment is delayed. Direct immunofluorescence or immunoperoxidase staining of skin biopsy specimens is a relatively rapid way of diagnosing RMSF. Serologic tests, including indirect immunofluorescence, latex agglutination, and enzyme immunoassay, that detect antirickettsial antibodies are available. However, these tests usually yield negative readings in the critical first days of the disease, as antibodies are not detectable until 7 to 10 days after the onset of the illness. Confirmation of the diagnosis using acute- and convalescent-phase serum samples is possible with these tests. The indirect hemagglutination antibody and immunofluorescent antibody tests are most useful because of their high sensitivity and specificity. The immunofluorescent test is especially beneficial because of its capacity to assess IgG and IgM levels. A highly specific and sensitive PCR assay for the detection of the spotted fever and typhus group of *Rickettsiae* was recently developed to provide rapid confirmation of the diagnosis when rickettsial loads are low. A complete blood count and liver function tests should be obtained. Most patients will have some degree of anemia or leukopenia, though in some cases the white

blood count may be elevated. Thrombocytopenia may occur in severe cases. Hepatic enzymes, bilirubin, and lactate dehydrogenase are often elevated. Blood cultures or a skin biopsy specimen may be used to confirm the diagnosis, but are not helpful in the initial diagnosis of spotted fevers due to the length of time they require for results. Rickettsiae do not stain well with Gram stain, and instead should be stained with Giemsa, Machiavello, or Castaneda stains.

Clinical and laboratory features, hospital course, and outcome of Rocky Mountain spotted fever in children

Buckingham SC, Marshall GS, Schutze GE, Woods CR, Jackson MA, Patterson LE, et al. J Pediatr 2007; 150: 180–4.

A retrospective chart review of 92 children with laboratory-diagnosed RMSF from 1990 to 2002 was performed. Results revealed the most common presenting symptoms were fever (98%), rash (97%), and nausea/vomiting (73%). Only four patients received antirickettsial therapy upon initial presentation. Three patients ultimately died, and 13 survivors had neurologic deficits at the time of discharge. These results demonstrate the commonness of delayed diagnosis and underscore the importance of the rapid initiation of appropriate therapy.

Laboratory diagnosis of Rocky Mountain spotted fever

Walker DH, Burday MS, Folds JD. South Med J 1980; 73: 1143–6.

Immunofluorescence staining of 16 skin biopsies proved this test to be the best for early diagnosis of RMSF. A specificity of 100% and sensitivity of 70% were reported.

Immunofluorescence must be conducted within 48 hours after initiating antirickettsial therapy.

A highly sensitive and specific real-time PCR assay for the detection of spotted fever and typhus group Rickettsiae

Stenos J, Graves SR, Unsworth NB. Am J Trop Hyg 2005; 73: 1083–5.

PCR was developed to target the citrate synthase gene of rickettsiae. This quantitative assay can confirm the diagnosis of a spotted disease when rickettsial numbers are low and makes possible the enumeration of rickettsiae in clinical specimens as well. *R. akari*, *R. australis*, *R. conorii*, *R. honei*, *R. marmionii*, *R. sibirica*, *R. rickettsii*, *R. typhus*, and *R. prowazekii* all were detectable by this PCR.

Identification of rickettsial infections by using cutaneous swab specimens and PCR

Bechah Y, Socolovschi C, Raoult D. Emerg Infect Dis 2011; 17: 83–6.

A study using noninvasive diagnostic cutaneous swabs was performed on nine human patients with suspected rickettsial infection. Eschars were swabbed in each of the nine patients, followed by DNA extraction from the swab. The DNA was tested by quantitative PCR for a specific gene sequence found in the *Rickettsiae* group. Spotted fever group rickettsial DNA was detected in eight of nine swab samples, thus demonstrating an effective noninvasive diagnostic test.

First-Line Therapies

• Doxycycline (in adults and children)	C
• Tetracycline (in adults)	C
• Azithromycin (in pregnant patients)	D

Rickettsia rickettsii is sensitive to tetracyclines, chloramphenicol, and rifampicin. Doxycycline is the therapy of choice and should be administered early in the illness. Adults and children weighing 45 kg or more should take 100 doses of doxycycline at 12-hour intervals either orally or intravenously. Children weighing less than 45.4 kg should receive 2.2 mg/kg body weight per dose administered twice daily.

No visible dental staining in children treated with doxycycline for suspected Rocky Mountain spotted fever

Todd SR, Dahlgren FS, Traeger MS, Beltrán-Aguilar ED, Marianos DW, Hamilton C, et al. J Pediatr 2015; 166: 1246–51.

This study failed to demonstrate enamel hypoplasia, dental staining, or tooth color changes in children <8 years of age who received short-term courses of doxycycline. Confidence in the use of doxycycline for children suspected of RMSF may be improved if the drug's label was changed to reflect these findings.

Fatal Rocky Mountain spotted fever in the United States, 1999–2007

Dahlgren FS, Holman RC, Paddock CD, Callinan LS, McQuiston JH. *Am J Trop Med Hyg* 2012; 86: 713–9.

The study highlights several risk groups more likely of dying of RMSF: children 5 to 9 years of age, American Indians, immunosuppressed patients, and severe cases experiencing delayed diagnosis and/or treatment. Doxycycline should be used as the first-line drug against RMSF for all ages, even in children less than 8 years old.

Rocky Mountain spotted fever in children

Woods CR. *Pediatr Clin North Am* 2013; 60: 455–70.

RMSF is often undifferentiated from many infections during the first days of illness. Accordingly, doxycycline should not be delayed pending confirmation even in children under the age of 8 years.

Risk factors for fatal outcome from Rocky Mountain spotted fever in a highly endemic area—Arizona, 2002–2011

Regan JJ, Traeger MS, Humpherys D, Mahoney DL, Martinez M, Emerson GL, et al. *Clin Infect Dis* 2015; 60: 1659–66.

Treatment with doxycycline during the first 3 days of the disease can decrease morbidity and mortality from RMSF in this region. Risk factors associated with doxycycline delay and fatal outcome include 1) gastrointestinal symptoms, 2) alcoholism, and 3) chronic lung disease. There should be a low threshold for initiating doxycycline, especially in endemic areas like tribal lands in Arizona.

Revisiting doxycycline in pregnancy and early childhood – time to rebuild its reputation?

Cross R, Ling C, Day NP, McGready R, Paris DH. *Expert Opin Drug Saf* 2016; 15: 367–82.

A systematic review of the literature on the use of doxycycline during pregnancy and in children revealed that there is no correlation between the use of doxycycline and teratogenic effects during pregnancy or dental staining in children.

Mediterranean spotted fever during pregnancy: case presentation and literature review

Bentov Y, Sheiner E, Kenigsberg S, Mazor M. *Eur J Obstet Gynecol*

Reprod Biol 2003; 107: 214–6.

Although the treatment of choice for Mediterranean spotted fever during pregnancy is chloramphenicol, azithromycin may be a viable alternative because of its effectiveness, safety in pregnancy and in children, high placental penetration, and increased compliance due to single daily dose.

Second-Line Therapies

• Tetracycline (in children)	C
• Azithromycin (adults and children)	B
• Clarithromycin (adults and children)	B

Analysis of risk factors for fatal Rocky Mountain spotted fever: evidence for superiority of tetracyclines for therapy

Holman RC, Paddock CD, Curns AT, Krebs JW, McQuiston JH, Childs JE. J Infect Dis 2001; 184: 1437–44.

A study of RMSF derived from reports received by the Centers for Disease Control and Prevention by state health departments and private physicians consisting of 5600 confirmed and probable cases occurring from 1981 to 1998. Age, race, and time of treatment with respect to onset of illness were used to stratify the patient population. Four treatments groups were studied: tetracycline without chloramphenicol, chloramphenicol without tetracycline, chloramphenicol with tetracycline, and neither chloramphenicol nor tetracycline. Patients with RMSF who did not receive tetracycline had an increased risk of death.

Clarithromycin versus azithromycin in the treatment of Mediterranean spotted fever in children: a randomized controlled trial

Cascio A, Colomba C, Antinori S, Paterson DL, Titone L. Clin Infect Dis 2002; 34: 154–8.

This open-label randomized controlled trial compared

azithromycin (10 mg/kg daily in one dose for 3 days) and clarithromycin (15 mg/kg daily in two divided doses for 7 days) in the treatment of Mediterranean spotted fever in children. Both of these agents may be suitable for children 8 years old and under.

Third-Line Therapy

• Chloramphenicol (pregnant and nonpregnant adults)	C
---	---

Analysis of risk factors for malignant Mediterranean spotted fever indicates that fluoroquinolone treatment has a deleterious effect

Botelho-Nevers E, Rovey C, Richet H, Raoult D. J Antimicrob Chemother 2011; 66: 1821–30.

Fluoroquinolones have been previously associated with failure in the treatment of typhus and scrub typhus, and fluoroquinolones are not recommended to treat any rickettsial diseases.

Typhus Group

Epidemic typhus

Epidemic typhus is caused by *R. prowazekii*, transmitted via the body louse. Recommended treatment is doxycycline taken orally (200 mg daily for 5 days), or intravenously in more severe cases.

Chloramphenicol is effective also. Prevention is crucial and can be achieved through bathing, washing clothes, and the use of insecticides.

Murine typhus

Murine typhus (or endemic typhus) is due to *R. typhi*, transmitted via the rat flea and the rat louse. Doxycycline, taken orally at 200 mg daily for 7 to 15 days or until 3 days of defervescence, is recommended. Chloramphenicol may also be effective, though relapses may occur. Prevention is achieved using insecticides and by controlling the rat population.

Scrub typhus

Scrub typhus is caused by *R. tsutsugamushi*, transmitted via larval mites. Tetracyclines are recommended in adults: doxycycline (200 mg daily) or tetracycline (2 g daily) for 2 to 14 days. Chloramphenicol, although effective, does not act as quickly as the tetracyclines.

Management Strategy

Specific Investigations

Epidemic typhus

- Serology: microimmunofluorescent and plate microagglutination tests

Murine typhus

- Serology: indirect fluorescent antibody, latex agglutination, solid-phase immunoassay

Scrub typhus

- Serology: indirect fluorescent antibody test

First-Line Therapies

Epidemic typhus

• Doxycycline	A
---------------	---

Murine typhus

• Doxycycline	A
---------------	---

Scrub typhus

• Doxycycline	A
• Azithromycin	A

Rickettsioses and Q fever in travelers (2004–2013)

Delord M, Socolovski C, Parola P. *Travel Med Infect Dis* 2014; 12: 443–58.

Doxycycline remains the standard treatment for all spotted fever group rickettsioses. Doxycycline is also the standard of treatment for scrub, murine, and epidemic typhus infections.

Doxycycline and rifampicin for mild scrub-typhus infections in northern Thailand: a randomized trial

Watt G, Kantipong P, Jongaskul K, Watcharapichat P, Phulsuksombati D, Strickman D. *Lancet* 2000; 356: 1057–61.

A randomized study of adults with mild scrub typhus in which patients received oral doxycycline 200 mg daily ($n = 28$), oral rifampicin 600 mg daily ($n = 26$), or oral rifampicin 900 mg daily ($n = 24$). Patients treated with rifampicin at either dosage demonstrated a significantly shorter median duration of pyrexia than did the doxycycline patients.

Doxycycline versus azithromycin for treatment of leptospirosis and scrub typhus

Phimda K, Hoontrakul S, Suttinont C, Chareonwat S, Losuwanaluk K, Chueasuwanchai S, et al. *Antimicrob Agents Chemother* 2007; 51: 3259–63.

A randomized controlled trial in which 296 patients were allocated to receive either a 7-day course of doxycycline or a 3-day course of azithromycin. The group studied included 57 patients (19.3%) with scrub typhus, 14 (4.7%) with murine typhus, 69 (23.3%) with

leptospirosis, and 11 (3.7%) with both leptospirosis and a rickettsial infection. Both regimens demonstrated similar effectiveness and fever clearance times. Azithromycin has fewer adverse effects, but is more expensive.

Second-Line Therapies

All typhus groups

• Rifampicin	A
• Chloramphenicol	D

Comparison of the effectiveness of five different antibiotic regimens on infection with *Rickettsia typhi*: therapeutic data from 87 cases

Gikas A, Doukakis S, Pediaditis J, Kastanakis S, Manios A, Tselentis Y. Am J Trop Med Hyg 2004; 70: 576–9.

A retrospective study of five different antibiotic regimens used in 87 patients with endemic typhus. Mean time to defervescence was 2.9 days for doxycycline, 4 days for chloramphenicol, and 4.2 days for ciprofloxacin.

Murine typhus in central Greece: epidemiological, clinical, laboratory, and therapeutic-response features of 90 cases

Chaliotis G, Kritsotakis EI, Psaroulaki A, Tselentis Y, Gikas A. Int J Infect Dis 2012; 16: e591–6.

A 5-year prospective study of 90 adult patients with murine typhus revealed a shorter time to defervescence using doxycycline in comparison to ofloxacin alone or doxycycline plus ofloxacin.

Rickettsialpox

Rickettsialpox is due to *R. akari*. The house mouse is the reservoir;

mites transmit the bacteria to humans. This disease is self-limited. It manifests as headache, fever, papulovesicular rash over the trunk and extremities, and an eschar in 80% of cases. Treatment in adults is doxycycline (200 mg daily) for 10 days.

Management Strategy

Specific Investigation

- Serology: complement fixation

First-Line Therapy

• Doxycycline	A
---------------	---

A case of rickettsialpox in Northern Europe

Renvoisé A, van't Wout JW, van der Schroeffer JG, Beersma MF, Raoult D. Int J Infect Dis 2012; 16: e221–2.

A patient was cured using doxycycline 200 mg per day for 10 days. Due to international interest in anthrax and bioterrorism, there has been a noticeable increase in the reported cases of rickettsialpox, as both diseases are eschar associated.

Q Fever

Q fever is caused by *Coxiella burnetii*. Transmission to humans occurs via aerosolized urine, feces, or birth products of ungulates (hoofed mammals). This disease usually has no skin findings. Patients often present with febrile illness, severe headache, and with or without pneumonia, hepatitis, or endocarditis. Vaccines for this occupational disease of sheep and dairy workers are not available in the United States.

Management Strategy

Acute Q fever

The primary treatment of choice in adults is doxycycline (100 mg orally twice a day for 14 days). Moxifloxacin (400 mg daily for 14 days) may be used as an alternative. In vitro the disease has been susceptible to fluoroquinolones, chloramphenicol, rifampin, and trimethoprim–sulfamethoxazole.

Chronic Q fever

The most common chronic manifestation is endocarditis, which is often resistant to treatment, due to the bacteriostatic rather than the bactericidal effects of antibiotics on *C. burnetii*. Currently, combination therapy with doxycycline (100 mg twice daily) and hydroxychloroquine (200 mg three times daily) is the mainstay of treatment given their bactericidal activity. Treatment must be carried out for a minimum of 18 months. The duration must further be tailored to the individual clinical response.

Specific Investigations

Acute Q fever

- Serology: complement fixation, immunofluorescent antibody
- PCR

Chronic Q fever

- Echocardiography
- Serology

High throughput detection of *Coxiella burnetii* by real-time PCR with internal control system and automated DNA preparation

Panning M, Kilwinski J, Greiner-Fischer S, Peters M, Kramme S, Frangoulidis D, et al. BMC Microbiol 2008; 8: 77.

A sensitive real-time PCR was established for the rapid screening of *C. burnetii* in local outbreaks. Although serology is the gold standard for diagnosis, it is inadequate for early case detection.

Evaluation of commonly used serological tests for the detection of *Coxiella burnetii* antibodies in well-defined acute and follow-up sera

Wegdam-Blans MC, Wielders CC, Meekelenkamp J, Korbeeck JM, Herremans T, Tjhie HT, et al. Clin Vaccine Immunol 2012; 19: 1105–10.

In this study of 126 patients with acute Q fever, detection of *Coxiella burnetii* antibodies during IgG phase I, IgG phase II, and IgM phase II was compared among enzyme-linked immunosorbent assay (ELISA), indirect fluorescent antibody test (IFAT), and complement fixation. Results demonstrated equal efficacy among the three serologic tests in diagnosing acute Q fever (within 3 months); however, IFAT was more sensitive in follow-up serology (12 months) and thus more beneficial for prevaccination screening programs.

First-Line Therapies

Acute Q fever

• β -Lactams	B
• Doxycycline	B
• Macrolides	B
• Quinolones	B

Chronic Q fever

• Doxycycline and hydroxychloroquine	B
--------------------------------------	----------

Second-Line Therapy

Chronic Q fever

• Quinolone and doxycycline	B
-----------------------------	----------

The natural history of acute Q fever: a prospective Australian cohort

Hopper B, Cameron B, Li H, Graves S, Stenos J, Hickie I, et al. QJM 2016; 109: 661–8.

Q fever is a worldwide zoonotic infection that can vary widely in severity and duration.

Ehrlichiosis

The ehrlichioses consists of two tickborne diseases: human monocytic ehrlichiosis due to *Ehrlichia chaffeensis* (the most common form in the United States) and human granulocytic ehrlichiosis due to *E. equi*. Both are found in mammalian reservoirs such as deer, dogs, and horses and are transmitted via ticks. Commonly encountered symptoms include fever, headaches, lack of appetite, and a highly variable exanthema. If inappropriately treated, ehrlichioses can progress to life-threatening respiratory failure and meningoencephalitis.

Management Strategy

Doxycycline (100 mg orally twice daily for adults, or 4 mg/kg daily in children 8 years of age and older) is the treatment of choice. The treatment ought to be continued for a minimum of 7 days and for 3 days after defervescence.

Specific Investigation

- Serology: immunofluorescent antibody

First-Line Therapy

• Doxycycline	A
---------------	----------

Fatal ehrlichial myocarditis in a healthy adolescent: a case report and review of the literature

Havens NS, Kinnear BR, Mató S. Clin Infect Dis 2012; 54: e113–4.

Doctors should have a low threshold for treatment with doxycycline during the peak season in endemic areas, as a delay of antibiotics has been shown to increase both morbidity and mortality. Therapy becomes even less effective if delayed beyond 1 week.

Second-Line Therapy

• Rifampin (rifampicin)	D
-------------------------	----------

Successful treatment of human monocytic ehrlichiosis with rifampin

Abusaada K, Ajmal S, Hughes L. Cureus 2016; 8: e444.

Rifampin (rifampicin) was successfully used in the treatment of a patient who had doxycycline allergy.

Clinical determinants of Lyme borreliosis, babesiosis, bartonellosis, anaplasmosis, and ehrlichiosis in an Australian cohort

Mayne PJ. Int J Gen Med 2014; 8:15–26.

In a study of 500 Lyme disease patients, 317 had coinfection with babesiosis, ehrlichiosis coinfection was noted in 3, and 30 patients had

a positive rickettsial serology.

Rosacea

John Berth-Jones

Rosacea is a common inflammatory skin disease, generally confined to the face, principally the cheeks, forehead, nose, and chin. In some cases lesions may extend onto the scalp and occasionally also onto the neck and the upper part of the body. A common early feature is flushing, often accompanied by a burning sensation. Inflammatory lesions (papulation and pustulation) are characteristic and may become florid. Vascular changes (telangiectasia and erythema) are also frequently observed. These are initially mild, but may later become very conspicuous. Other later features are the development of

lymphedema, thickening, and induration. On the nose and, less often, the ears, forehead, or chin, hypertrophy and lymphedema of subcutaneous tissue may develop into distinct swellings known as *phymas*, of which rhinophyma is most familiar. Ocular involvement is frequent and manifests as a sensation of grittiness, which may be accompanied by conjunctivitis, blepharitis, episcleritis, chalazion, hordeolum, iritis, and occasionally severe keratitis.

Management Strategy

Rosacea is a clinical diagnosis. It should be noted that the classical progression described earlier is far from consistent, and features of rosacea may develop in isolation or in any combination or sequence.

Patients may find it beneficial to *avoid “triggers” — alcohol, spicy food, hot drinks, etc.*, which may induce flushing and promote the development of telangiectasia. Exposure to irritants should be avoided, and emollients can be helpful. *Cosmetic camouflage* of the erythema and telangiectasia may be worthwhile. *Facial massage* may promote lymphatic drainage and reduce the development of lymphedema. Papulation and pustulation can be effectively suppressed using a variety of *topical and systemic antibiotics, topical ivermectin, retinoids*, and other agents described later. Controlling inflammation with these modalities may also reduce erythema, but does not usually prove very helpful for suppressing flushing and has little effect on established telangiectasia. Erythema can be treated more specifically with topical application of vasoconstrictors, of which *brimonidine* is best established. Telangiectasia can be effectively treated by physical measures to ablate the vessels, such as *intense pulsed light or vascular lasers*. Flushing is usually the most difficult feature to treat, but sometimes improves during treatment of erythema and telangiectasia. Ocular rosacea is often treated symptomatically with a range of *“artificial tears”* (the ophthalmic equivalent of emollients). *Systemic tetracyclines*, used as for cutaneous rosacea, are also helpful. The use of *retinoids* for rosacea requires special care in patients with eye involvement and may be poorly tolerated. Treatments are discussed later in sections focused on inflammatory rosacea, erythematotelangiectatic rosacea, flushing, lymphedema, ocular rosacea, and rosacea fulminans. Treatments for rhinophyma and perioral dermatitis are described in separate chapters.

Specific Investigations

In selected cases

- Exclude carcinoid syndrome; urine 5-HIAA, plasma serotonin, chromogranin-A
- Exclude lupus; serology, histology

Inflammatory rosacea

First-Line Treatments

• Topical metronidazole	A
• Topical ivermectin	A
• Topical azelaic acid	A
• Oral tetracyclines	A
• Oral erythromycin	C
• Emollients	C

The efficacy of metronidazole 1% cream once daily compared with metronidazole cream twice daily and their vehicles in rosacea: a double-blind clinical trial

Jorizzo JL, Lebwohl M, Tobey RE. J Am Acad Dermatol 1998; 39: 502–4.

This study confirmed improvements in numbers of inflammatory

lesions and in erythema relative to placebo. However, there was no apparent difference between once-daily and twice-daily application.

Topical metronidazole maintains remissions of rosacea

Dahl MV, Katz HI, Krueger GG, Millikan LE, Odom RB, Parker F, et al. Arch Dermatol 1998; 134: 679–83.

Eighty-eight subjects who had responded to treatment with systemic tetracycline and topical metronidazole were randomized to receive 0.75% metronidazole gel or placebo gel for 6 months. In those applying the metronidazole, 23% developed a relapse of papulopustular lesions and 55% a worsening of erythema, compared with 42% and 74% of subjects, respectively, in the placebo gel group.

Efficacy and safety of ivermectin 1% cream in treatment of papulopustular rosacea: results of two randomized, double-blind, vehicle-controlled pivotal studies

Stein L, Kircik L, Fowler J, Tan J, Draelos Z, Fleischer A, et al. J Drugs Dermatol 2014; 13: 316–23.

Each study recruited nearly 700 subjects. Treatments were applied once daily. At 12 weeks assessments of “clear” or “almost clear” were seen in 38.4% and 40.1% of the ivermectin group and 11.6% and 18.8% of the vehicle group ($p < 0.001$).

Superiority of ivermectin 1% cream over metronidazole 0.75% cream in treating inflammatory lesions of rosacea: a randomized, investigator-blinded trial

Taieb A, Ortonne JP, Ruzicka T, Roszkiewicz J, Berth-Jones J, Peirone MH, et al. Br J Dermatol 2015; 172: 1103–10.

A 16-week study with 962 subjects. Subjects receiving ivermectin cream experienced an 83% reduction in inflammatory lesion count (the primary end point), compared with a reduction of 74% in the metronidazole group ($p < 0.001$).

In separate reports from this trial, topical ivermectin has also been shown to improve quality of life more than metronidazole and to induce longer remissions (median 115 vs. 85 days).

A randomized, double-blind, placebo-controlled trial of the combined effect of doxycycline hyclate 20 mg tablets and metronidazole 0.75% topical lotion in the treatment of rosacea

Sanchez J, Somolinos AL, Almodovar PI, Webster G, Bradshaw M,

Powala C. J Am Acad Dermatol 2005; 53: 791–7.

Combinations of topical and systemic treatment are often used and seem likely to be more effective than either used alone. In this study the addition of low-dose (20 mg) doxycycline improved the response to topical metronidazole.

Double-blind comparison of azelaic acid 20% cream and its vehicle in treatment of papulo-pustular rosacea

Bjerke R, Fyrand O, Graupe K. Acta Derm Venereol 1999; 79: 456–9.

A 3-month randomized, double-blind study compared the efficacy and safety of azelaic acid 20% cream, applied twice daily, with its vehicle in 116 patients. Azelaic acid cream produced significantly greater mean reductions in total inflammatory lesions than did vehicle: 73.4% vs. 50.6%, respectively. Erythema also responded.

A clinical trial of tetracycline in rosacea

Sneddon IB. Br J Dermatol 1966; 78: 649–52.

A double-blind trial with 78 evaluable subjects comparing tetracycline 250 mg twice daily with placebo after 4 weeks of treatment. There was a significantly superior response to active treatment, even though a pronounced placebo effect was observed. During subsequent follow-up it was found that some patients could be completely controlled using only 100 mg daily.

Two randomized phase III clinical trials evaluating anti-inflammatory dose doxycycline (40-mg doxycycline, USP capsules) administered once daily for treatment of rosacea

Del Rosso JQ, Webster GF, Jackson M, Rendon M, Rich P, Torok H, et al. J Am Acad Dermatol 2007; 56: 791–802.

Doxycycline appears effective even at low doses.

A double-blind study of 1% metronidazole cream versus systemic oxytetracycline therapy for rosacea

Nielsen PG. Br J Dermatol 1983; 109: 63–65.

Improvement occurred in 90% of the patients. There was no significant difference between the treatments.

Both tetracycline and oxytetracycline are generally used at the dose of 250 to 500 mg twice daily. Other systemic tetracyclines, such as minocycline 100 mg daily, doxycycline 40 mg or 100 mg daily, and lymecycline 408 mg daily, are also often prescribed. These offer the advantage of once-daily

administration, and their absorption is less influenced by dietary calcium, so they can be taken with food. Erythromycin 250 to 500 mg twice daily is also often prescribed and widely held to be effective and can be useful when rosacea occurs in children, for whom tetracyclines are contraindicated.

Beneficial use of Cetaphil moisturizing cream as part of a daily skin care regimen for individuals with rosacea

Laquieze S, Czernielewski J, Baltas E. J Dermatol Treat 2007; 18: 158–62.

Twice-daily application of a moisturizer appeared beneficial in this open study on 20 patients.

Second-Line Treatments

• Topical erythromycin	C
• Topical clindamycin	C
• Oral metronidazole	A
• Topical benzoyl peroxide	A
• Ampicillin	A
• Azithromycin	B

Topically applied erythromycin in rosacea

Mills OH, Kligman AM. Arch Dermatol 1976; 112: 553–4.

A 2% solution applied twice daily to 15 patients produced a 50% to 100% improvement in 87% of cases, and treatment was effective by 4 weeks. Once-daily application was sufficient once the disease was controlled.

Treatment of rosacea: topical clindamycin versus oral tetracycline

Wilkin JK, DeWitt S. Int J Dermatol 1993; 32: 65–67.

A randomized, blinded trial comparing topical clindamycin lotion twice daily with oral tetracycline in 43 patients evaluated over 12 weeks. Similar improvements were found in both groups, although clindamycin was superior in eradication of pustules.

Double-blind, randomized, vehicle-controlled clinical trial of once-daily benzoyl peroxide/clindamycin topical gel in the treatment of patients with moderate to severe rosacea

Breneman D, Savin R, VandePol C, Vamvakias G, Levy S, Leyden J. Int J Dermatol 2004; 43: 381–7.

This combination of 5% benzoyl peroxide and 1% clindamycin was effective and well tolerated.

Treatment of rosacea by metronidazole

Pye RJ, Burton JL. Lancet 1976; 1: 1211–2.

A double-blind, placebo-controlled, parallel-group trial demonstrating the efficacy of oral metronidazole 200 mg twice daily after 6 weeks of treatment. Ten out of 14 patients treated with metronidazole showed a good response.

A double-blinded trial of metronidazole versus oxytetracycline therapy for rosacea

Saihan EM, Burton JL. Br J Dermatol 1980; 102: 443–5.

Forty patients were treated for 12 weeks with oxytetracycline 250 mg twice daily or metronidazole 200 mg twice daily. On both drugs the degree of improvement was greater after 12 weeks than after 6 weeks. There was no significant difference between them.

Although metronidazole is generally well tolerated and it has been used long term, there is a risk of peripheral neuropathy if it is used for longer than 3 months.

Topical treatment of acne rosacea with benzoyl peroxide acetone gel

Montes LF, Cordero AA, Kriner J. Cutis 1983; 32: 185–90.

Benzoyl peroxide gel (5% increasing to 10%) was significantly superior to vehicle, although it was poorly tolerated and there was a high dropout rate.

Comparative effectiveness of tetracycline and ampicillin in rosacea. A controlled trial

Marks R, Ellis J. Lancet 1971; 2: 1049–52.

A double-blind, placebo-controlled trial lasting 6 weeks and completed by 56 patients. Both antibiotics were significantly more effective than placebo. Tetracycline was apparently (but not significantly) more effective than ampicillin.

A novel treatment for acne vulgaris and rosacea

Elewski BE. J Eur Acad Dermatol Venereol 2000; 14: 423–4.

Ten patients were treated in an open study of azithromycin, 500 mg on day 1, followed by 250 mg/day for 4 consecutive days beginning on the first and fifteenth days of each month for 3 months. All patients improved, and nine were clear by 3 months.

Oral use of azithromycin for the treatment of acne rosacea

Fernandez-Obregon A. Arch Dermatol 2004; 140: 489–90.

Ten patients responded well to azithromycin 250 mg/day for 3 days each week (Monday, Wednesday, and Friday) within 4 weeks. Ocular symptoms also improved.

Azithromycin has a relatively long half-life and is therefore suited to this sort of regimen.

Third-Line Treatments

• Systemic isotretinoin	B
• Topical tretinoin	C
• Topical adapalene	B
• Topical sulfur ± sulfacetamide	B
• Topical corticosteroids	D
• Topical bifonazole	D
• Photodynamic therapy	D
• Spironolactone	D
• <i>Demodex</i> eradication	B
• Praziquantel 3% ointment	B
• <i>Helicobacter pylori</i> eradication	D
• Sunscreens	E
• Topical tacrolimus	C
• Topical pimecrolimus	D
• Octreotide	C
• Inhibition of ovulation	C
• Topical 1-methylnicotinamide	C
• Oral nicotinamide with zinc	C
• Zinc sulfate	B
• Long-pulsed, 1064-nm, Nd:YAG laser	C
• Kanuka honey	B

A randomized-controlled trial of oral low-dose isotretinoin for difficult-to-treat papulopustular rosacea

Sbidian E, Vicaut É, Chidiack H, Anselin E, Cribier B, Dréno B, et al. J Invest Dermatol 2016; 136: 1124–9.

One hundred and fifty-six subjects used isotretinoin 0.25 mg/kg/day or placebo over a 4-month treatment period. Response (90% reduction in inflammatory lesions) was observed in 57% on isotretinoin vs. 10% on placebo ($p < 0.0001$). The proportions of patients discontinuing therapy due to adverse events were similar in the two groups.

There have been several reports of the use of isotretinoin at doses of 10 to 60 mg/day or 0.5 to 1 mg/kg/day. Variable relapse rates have been reported after discontinuing the drug, there being a trend toward more frequent relapse in those given lower total doses. However, doses often need to be kept low to avoid aggravating ocular symptoms. Partly for this reason, some investigators have advocated the use of continuous low-dose therapy with isotretinoin.

Topical tretinoin for rosacea: a preliminary report

Kligman AM. J Dermatol Treat 1993; 4: 71–3.

Topical tretinoin 0.025% for 6 to 12 months improved rosacea in about 70% of cases in this open study with 19 patients. Improvement was seen in telangiectasia as well as inflammatory lesions.

Adapalene vs. metronidazole gel for the treatment of rosacea

Altinyazar HC, Koca R, Tekin NS, Estürk E. Int J Dermatol 2005; 44: 252–5.

In an investigator-blinded, parallel-group trial with 55 patients, adapalene 0.1% gel produced results similar to those of metronidazole 0.75% gel.

Topical treatment with sulfur 10% for rosacea

Blom I, Hornmark A-M. Acta Derm Venereol 1984; 64: 358–9.

A randomized study with 40 patients. Treatment duration was 4 weeks. Topical sulfur 10% in a cream base (Diprobase) was as effective as oral lymecycline 150 mg/day. A greater reduction in inflammatory lesions was observed in the group treated with sulfur,

although there were a greater number of lesions at baseline in this group.

The treatment of rosacea: the safety and efficacy of sodium sulfacetamide 10% and sulfur 5% lotion (Novacet) is demonstrated in a double-blind study

Saunders DN, Miller R, Gratton D, Danby W, Griffiths C, Phillips S. J Dermatol Treat 1997; 8: 79–85.

Efficacy of 10% sodium sulfacetamide and 5% sulfur was demonstrated in an 8-week randomized, vehicle-controlled, multicenter study with 103 patients.

Comparative study of triamcinolone acetonide and hydrocortisone 17-butyrate in rosacea with special regard to the rebound phenomenon

Go MJ, Wuite J. Dermatologica 1976; 152: 239–46.

In this study with 19 subjects, topical steroids given in conjunction with tetracycline did not cause a rebound phenomenon when the steroids were discontinued.

The place of steroids in rosacea is ill defined and probably very limited, although their use has been reported in conjunction with standard treatments.

Treatment of rosacea with bifonazole cream: a preliminary report

Veraldi S, Schianchi-Veraldi R. Ann Ital Derm Clin Sper 1990; 44: 169–71.

Topical bifonazole 1% cream was used successfully in eight cases of rosacea, with no recurrence at 3 months.

Photodynamic therapy in a series of rosacea patients

Bryld LE, Jemec GB. J Eur Acad Dermatol Venereol 2007; 21: 1199–202.

A series of 17 patients with rosacea refractory to previous therapy were treated with photodynamic therapy using 16% methyl aminolevulinic acid (Metvix) cream applied for 3 hours, followed by 37 J/cm² of red light. Initially patients received one or two treatments at an interval of 1 week, and up to four treatments were used on each treated area if required. A good response was observed in 10 cases.

Oral spironolactone therapy in male patients with rosacea

Aizawa H, Niimura M. J Dermatol 1992; 19: 293–7.

Spironolactone at a dose of 50 mg/day for 4 weeks was reported to benefit 7 of 13 male patients with rosacea. Two of the patients did not tolerate the drug.

***Demodex folliculorum* and topical treatment: action evaluated by standardized skin surface biopsy**

Forton F, Seys B, Marchal JL, Song AM. Br J Dermatol 1998; 138: 461–6.

This study of 34 patients with high *Demodex* carriage compared the miticidal effect of topical metronidazole, permethrin, sulfur, lindane, crotamiton, and benzyl benzoate. Benzyl benzoate and crotamiton had particular effects on the mite population, suggesting that they may be appropriate treatment for some cases of rosacea and “rosacea-like demodecosis.”

Permethrin 5% cream versus metronidazole 0.75% gel for the treatment of papulopustular rosacea. A randomized double-blind placebo-controlled study

Koçak M, Yagli S, Vahapoglu G, Eksioglu M. Dermatology 2002; 205: 265–70.

Treatments were applied twice daily for 2 months. Permethrin was more effective in improving erythema and papules than placebo and as effective as metronidazole 0.75% gel, but had no effect on telangiectasia, rhinophyma, or pustules. Reduction of *Demodex* counts was significantly greater with permethrin than with metronidazole or placebo.

Treatment of rosacea-like demodicidosis with oral ivermectin and topical permethrin cream

Forstinger C, Kittler H, Binder M. J Am Acad Dermatol 1999; 41: 775–7.

A patient suffering from a follicular, papulopustular facial eruption with a long history of unsuccessful treatment responded to ivermectin 200 µg/kg. This was followed by once-weekly application of 5% permethrin cream to prevent reinfestation.

Clinical and experimental assessment of the effects of a new topical treatment with praziquantel in the management of rosacea

Bribeche MR, Fedotov VP, Gladichev VV, Pukhalskaya DM, Kolitcheva NL. *Int J Dermatol* 2015; 54: 481–7.

A single-blind, randomized study with 65 subjects treated with 3% praziquantel ointment or vehicle ointment applied twice daily for 16 weeks. Significant benefit was observed relative to placebo in investigators' global assessments, erythema assessment scale, and Dermatology Life Quality Index (DLQI).

Praziquantel is a broad-spectrum antiparasitic agent that has been proposed to act by suppressing Demodex.

There are increased numbers of Demodex mites in rosacea, suggesting that they are implicated in the pathogenesis. This has provided a rationale for the use of a range of therapies aimed at eradication of the mites, including topical ivermectin, which also has antiinflammatory properties and is now regarded as a first-line therapy.

***Helicobacter pylori* eradication treatment reduces the severity of rosacea**

Utas S, Ozbakir O, Turasan A, Utas C. *J Am Acad Dermatol* 1999; 40: 433–5.

Thirteen patients with rosacea having evidence of *H. pylori* infection received a course of amoxicillin 500 mg three times daily for 2 weeks, metronidazole 500 mg three times daily for 2 weeks, and bismuth subcitrate 300 mg four times daily for 4 weeks. There was a significant reduction in the severity of the rosacea at the end of treatment.

The effect of the treatment of *Helicobacter pylori* infection on rosacea

Bamford JL, Tilden RL, Blankush JL, Gangeness DE. *Arch Dermatol* 1999; 135: 659–63.

A randomized, double-blind, placebo-controlled trial of *H. pylori* eradication with clarithromycin and omeprazole or placebo. There was no difference in the rosacea between the two groups at 60 days.

Several investigators have proposed an association between H. pylori and rosacea, although this remains highly controversial.

Effective sunscreen ingredients and cutaneous irritation in patients with rosacea

Nichols K, Desai N, Lebwohl MG. *Cutis* 1998; 61: 344–6.

Patients with rosacea are particularly susceptible to the irritation caused by sunscreen ingredients. Formulations with protective

constituents, such as dimethicone and cyclomethicone, may be preferable.

Tacrolimus effect on rosacea

Bamford JTM, Elliott BA, Haller IV. J Am Acad Dermatol 2004; 50: 107–8.

Topical tacrolimus 0.1% reduced erythema but not papulopustular lesions in this open study with 24 subjects.

Pimecrolimus for treatment of acne rosacea

Crawford KM, Russ B, Bostrom P. Skinmed 2005; 4: 147–50.

An open-label study on 12 patients. Improvements were seen in erythema and papulopustular lesions.

Pimecrolimus cream 1% for papulopustular rosacea: a randomized vehicle-controlled double-blind trial

Weissenbacher S, Merkl J, Hildebrandt B, Wollenberg A, Braeutigem M, Ring J, et al. Br J Dermatol 2007; 156: 728–32.

Pimecrolimus was no more effective than placebo.

Topical tacrolimus and pimecrolimus have both been reported to induce rosacea-like eruptions. If there is a role for these topical agents in the management of rosacea, this remains to be clarified.

Incidental control of rosacea by somatostatin

Piérard-Franchimont C, Quatresooz P, Piérard GE. Dermatology 2003; 206: 249–51.

Four cases improved during incidental treatment of diabetic retinopathy with a long-acting octreotide injection (Sandostatin 20 mg) monthly.

Octreotide is a somatostatin analog known to be highly active in suppressing the secretion of vasoactive hormones by carcinoid tumors and reduces the flushing associated with the carcinoid syndrome.

Effect of oral inhibitors of ovulation in treatment of rosacea and dermatitis perioralis in women

Spirov G, Berova N, Vassilev D. Aust J Dermatol 1971; 12: 149–54.

An oral contraceptive was associated with improvement of rosacea in 90% of 30 women. An open, uncontrolled study.

Topical application of 1-methylnicotinamide in the treatment of

rosacea: a pilot study

Wozniacka A, Sysa-Jedrzejowska A, Adamus J, Gebicki J. Clin Exp Dermatol 2005; 30: 632–5.

This compound is a metabolite of nicotinamide with antiinflammatory properties. Thirty-four patients were treated twice daily with a gel containing 0.25% methyl nicotinamide in this open-label pilot study. Improvement was good in 9 cases and moderate in 17.

The Nicomide Improvement in Clinical Outcomes Study (NICOS): results of an 8-week trial

Niren NM, Torok HM. Cutis 2006; 77: 17–28.

This compound formulation (Nicomide), comprising nicotinamide 750 mg, zinc 25 mg, copper 1.5 mg, and folic acid 500 µg, was reported as effective in an open-label study on 198 patients with acne vulgaris and/or rosacea.

Oral zinc sulfate in the treatment of rosacea: a double-blind, placebo-controlled study

Sharquie KE, Najim RA, Al-Salman HN. Int J Dermatol 2006; 45: 857–61.

Zinc sulfate 100 mg/day proved more effective than placebo in this crossover trial with 25 patients.

Efficacy of the long-pulsed 1064-nm neodymium:yttrium-aluminum-garnet laser (LPND) (rejuvenation mode) in the treatment of papulopustular rosacea (PPR): a pilot study of clinical outcomes and patient satisfaction in 30 cases

Lee JH, Kim M, Bae JM, Cho BK, Park HJ. J Am Acad Dermatol 2015; 73: 333–6.

Improvement was reported after three treatment sessions at 4-week intervals. This was an uncontrolled study in which subjects also applied moisturizer and sunscreen and avoided known triggers.

Randomised controlled trial of topical kanuka honey for the treatment of rosacea

Braithwaite I, Hunt A, Riley J, Fingleton J, Kocks J, Corin A, et al. BMJ Open 2015; 5: e007651.

An assessor-blinded study. Honey or cetomacrogol cream (control) were applied twice daily. At 8 weeks 24/68 in the honey group and

12/69 in the control group had a ≥ 2 point improvement in global assessment compared with baseline ($p = 0.02$).

Kanuka is a tree species related to manuka.

Erythematotelangiectatic rosacea

First-Line Therapies

• Cosmetic camouflage	C
• Brimonidine tartrate	A
• Intense pulsed light	B
• Vascular lasers	B

Decorative cosmetics improve the quality of life in patients with disfiguring skin diseases

Boehncke WH, Ochsendorf F, Paeslack I, Kaufmann R, Zollner TM. Eur J Dermatol 2002; 12: 577–80.

Twenty women with a range of dermatoses, including nine with rosacea, completed the DLQI questionnaire before and after instruction by a cosmetician. The mean score improved from 9.2 to 5.5.

Once-daily topical brimonidine tartrate gel 0.5% is a novel treatment for moderate to severe facial erythema of rosacea: results of two multicentre, randomized and vehicle-controlled studies

Fowler J, Jarratt M, Moore A, Meadows K, Pollack A, Steinhoff M, et al. Br J Dermatol 2012; 166: 633–41.

Two placebo-controlled trials. One study examined response to a

single application using a range of concentrations. The other examined results from 4 weeks of treatment once or twice daily and followed by 4 weeks washout. Reduced redness was apparent at 30 minutes and persisted for 12 hours. There was no evidence of tachyphylaxis or rebound.

Although not an ideal formulation, brimonidine ophthalmic drops can also be effective. Additionally, there have been several reports of rebound erythema secondary to brimonidine.

Objective and quantitative improvement of rosacea-associated erythema after intense pulsed light treatment

Mark KA, Sparacio RM, Voigt A, Marenus K, Sarnoff DS. *Dermatol Surg* 2003; 29: 600–4.

Objective assessments were performed on four subjects before and after intense pulsed light (IPL) therapy for rosacea. Five treatments at 3-week intervals were undertaken using the Photoderm VL machine, with a 515-nm filter, a single pulse of 3 ms duration, and various fluences. Facial blood flow was reduced by 30%, the area of the cheek occupied by telangiectasia was reduced by 29%, and erythema intensity was reduced by 21%.

Treatment of rosacea with intense pulsed light

Taub AF. *J Drugs Dermatol* 2003; 2: 254–9.

Thirty-two patients underwent one to seven treatments. Eighty-three percent had reduced redness, 75% noted reduced flushing, and 64% noted fewer acneiform breakouts. The treatment was well tolerated.

IPL can improve not only telangiectasia, but also erythema and flushing, and is generally better tolerated than lasers. Some expertise is required for optimal results.

Neodymium-yttrium aluminum garnet laser versus pulsed dye laser in erythemato-telangiectatic rosacea: comparison of clinical efficacy and effect on cutaneous substance (P) expression

Salem SA, Abdel Fattah NS, Tantawy SM, El-Badawy NM, Abd El-Aziz YA. *J Cosmet Dermatol* 2013; 12: 187–94.

A split-face study on 15 patients treated on three occasions at 4-week intervals. Excellent response was achieved in 73.3% of patients after Nd-YAG and in 53.3% of patients after PDL.

Comparative effectiveness of nonpurpuragenic 595-nm pulsed dye laser and microsecond 1064-nm neodymium:yttrium-aluminum-garnet laser for treatment of diffuse facial erythema: a double-blind randomized controlled trial

Alam M, Voravutinon N, Warycha M, Whiting D, Nodzenski M, Yoo S, et al. *J Am Acad Dermatol* 2013; 69: 438–43.

A split-face study in which 14 patients completed four treatments at 1-month intervals. Subjects rated redness as improved by 52% as a result of PDL and 34% as a result of Nd:YAG. Nd:YAG was somewhat less painful.

The effect of pulsed dye laser on the Dermatology Life Quality Index in erythematotelangiectatic rosacea patients: an assessment

Shim TN, Abdullah A. *J Clin Aesthet Dermatol* 2013; 6: 30–2.

Mean DLQI improved from 17.3 to 4.3 ($p < 0.0001$) in this study of 20 patients.

How laser surgery can help your rosacea patients

West T. *Skin Aging* 1998; 43–6.

A review of the use of lasers and IPL for rosacea telangiectasia. IPL is considered to require more operator skill than the KTP or pulsed dye lasers. This article includes recommended parameters for the use of lasers and IPL.

Hair dryer use to optimize pulsed dye laser treatment in rosacea patients

Kashlan L, Graber EM, Arndt KA. *J Clin Aesthet Dermatol* 2012; 5: 41–4.

This reviews a range of physical and pharmacologic approaches to increasing efficacy of photothermolysis by inducing vasodilation, including exercising, overdressing, consuming trigger foods and beverages, inverting the head, and topical nicotinic acid. Possible agents not yet reported in the literature might include topical nitroglycerin, tetracaine, and lidocaine.

Second-Line Therapies

• Oxymetazoline	E
• Ondansetron	E
• Botulinum toxin	D
• Cromolyn sodium	D
• Rifaximin	D

Successful treatment of the erythema and flushing of rosacea using a topically applied selective alpha1-adrenergic receptor agonist, oxymetazoline

Shanler SD, Ondo AL. Arch Dermatol 2007; 143: 1369–71.

Two cases of erythematotelangiectatic rosacea were treated with a commercially available 0.05% solution of oxymetazoline hydrochloride applied once daily to the face. Redness and flushing were markedly improved.

A 1% cream formulation of oxymetazoline is now commercially available.

The response of erythematous rosacea to ondansetron

Wollina U. Br J Dermatol 1999; 140: 561–2.

Two cases responded to the serotonin receptor antagonist ondansetron. This drug is used mainly as an antiemetic during chemotherapy. It was initially given intravenously at a dose of 12 mg daily and later orally at doses of 4 to 8 mg twice daily. Erythema and ocular symptoms also improved.

Improvement of erythema and flushing has also been reported with granisetron (see later).

Botulinum toxin for the treatment of refractory erythema and

flushing of rosacea

Park KY, Hyun MY, Jeong SY, Kim BJ, Kim MN, Hong CK. *Dermatology* 2015; 230: 299–301.

Impact of intradermal abobotulinumtoxinA on facial erythema of rosacea

Bloom BS, Payongayong L, Mourin A, Goldberg DJ. *Dermatol Surg* 2015; 41 (Suppl 1): S9–16.

Two reports of facial erythema (and probably also flushing) responding to facial intradermal botulinum toxin in 2 and 15 cases, respectively.

Mast cells are key mediators of cathelicidin initiated skin inflammation in rosacea

Muto Y, Wang Z, Vandenberghe M, Two A, Gallo RL, DiNardo A. *J Invest Dermatol* 2014; 134: 2728–36.

A randomized, vehicle-controlled trial. Ten subjects with erythematotelangiectatic rosacea applied cromolyn sodium 4% solution or placebo twice daily for 8 weeks. Erythema was reduced in the treatment group.

Rosacea and small intestinal bacterial overgrowth: prevalence and response to rifaximin

Weinstock LB, Steinhoff M. *J Am Acad Dermatol* 2013; 68: 875–76.

Clearing or marked improvement of rosacea was reported in 46% of a group of 28 patients treated for small intestinal bacterial overgrowth with this nonabsorbed antibiotic. Most patients had vascular rosacea, but ocular disease also improved.

Rosacea flushing

The flushing associated with rosacea is often the most difficult symptom to treat. This often persists even when the inflammatory component is effectively treated. However, some improvement of flushing is not uncommon when erythematotelangiectatic disease is treated with the various modalities described earlier. Additional approaches are described here.

First-Line Therapies

• Clonidine	D
• Rilmenidine	D
• β -Blockers	D
• Naloxone	D
• Cosmesis	C
• Pulsed dye laser	D
• Intense pulsed light	D
• Hypnosis	E
• Granisetron	D
• Botulinum toxin	D

Clonidine and facial flushing in rosacea

Cunliffe WJ, Dodman B, Binner JG. Br Med J 1977; 1: 105.

Clonidine 0.05 mg twice daily was compared with placebo in a crossover trial with 17 subjects. Five reported improvement in

severity and frequency of flushing while on clonidine.

Flushing in rosacea: a possible mechanism

Guarrera M, Parodi A, Cipriani C, Divano C, Rebora A. Arch Dermatol Res 1982; 272: 311–6.

A study of possible pharmacologic inhibitors of rosacea flushing. A single 0.15-mg dose of clonidine inhibited the flushing induced by ingestion of 100 mL of beer in all five patients tested. The testing was undertaken 1 hour after the oral dose so that the blood level of clonidine was at its peak during the investigation.

Effect of subdepressor clonidine on flushing reactions in rosacea. Change in malar thermal circulation index during provoked flushing reactions

Wilkin JK. Arch Dermatol 1983; 119: 211–4.

Clonidine can reduce menopausal flushing. In this study clonidine 0.05 mg given orally twice daily did not suppress the flushing reactions provoked by water at 60°C, red wine, and chocolate. Clonidine did reduce the temperature of malar skin, suggesting a vasoconstrictor effect.

Rilmenidine has also been assessed in a small trial with a suggestion of benefit.

Effect of nadolol on flushing reactions in rosacea

Wilkin JK. J Am Acad Dermatol 1989; 20: 202–5.

A placebo-controlled trial of nadolol 40 mg daily. Spontaneous flushing and flushing provoked in the laboratory by challenges with hot drinks, alcohol, and nicotinic acid were evaluated in 15 subjects. Nadolol had no effect on objective measurements of provoked flushing. There was a trend toward improvement in patient-reported spontaneous flushing.

Alcohol-induced rosacea flushing blocked by naloxone

Bernstein JE, Soltani K. Br J Dermatol 1982; 107: 59–61.

In an experimental setting five subjects with rosacea were investigated to determine whether alcohol-induced rosacea flushing could be inhibited by naloxone 0.8 mg subcutaneously, placebo injection, or chlorpheniramine 12 mg orally. Naloxone effectively prevented alcohol-induced rosacea flushing. Chlorpheniramine or placebo had no consistent effect. This suggests that there may be a

role for opioid antagonists in inhibition of this reaction.

Hypnosis in dermatology

Shenefelt PD. Arch Dermatol 2000; 136: 393–9.

Hypnosis has been reported to improve the blushing associated with rosacea.

This is a comprehensive review of the many potential applications for hypnosis in dermatology.

Influence of the 5-HT₃ receptor antagonist granisetron on erythema and flushing tendency in rosacea patients

Jansen T. Kosmet Med 2005; 26: 22–4.

Both symptoms improved in a series of 10 patients treated with this antiemetic agent.

Rosacea lymphedema (Morbihan disease)

This is a particularly refractory chronic form of rosacea that has received little attention in the literature. Indurated edema develops mainly over the upper half of the face. Treatment is difficult, and the evidence base is very limited. Measures that are generally employed include control of underlying inflammatory rosacea using broad-spectrum antibiotics and facial massage to improve lymphatic drainage.

First-Line Therapies

• Broad-spectrum antibiotics	E
• Facial massage	E
• Isotretinoin	D
• Prednisolone with metronidazole	E
• Prednisolone and doxycycline	E
• CO ₂ laser blepharoplasty	E
• Surgical debulking of the eyelids	E

Successful long-term use of oral isotretinoin for the management of Morbihan disease: a case series report and review of the literature

Smith LA, Cohen DE. Arch Dermatol 2012; 148: 1395–8.

Five cases were treated with doses from 40 to 80 mg/day for 10 to 24 months. Treatment was successful, with disease-free follow-up of 1 to 24 months. However, substantial improvement was not seen until 6 months.

Persistent facial swelling in a patient with rosacea

Scerri L, Saihan EM. Arch Dermatol 1995; 131: 1069–74.

A marked reduction in facial swelling was reported in one case from a reducing course of prednisolone, starting at 30 mg daily, and metronidazole 400 mg/day over a 4-month period, followed by metronidazole 200 mg/day.

Successful treatment of Morbihan's disease with oral prednisolone and doxycycline

Ranu H, Lee J, Hee TH. Dermatolog Ther 2010; 23: 682–5.

A single case responded to doxycycline 100 mg daily when after 6 weeks this was combined with prednisolone at the dose of 20 mg daily for 2 weeks, then 10 mg for 1 week.

Morbihan's disease: treatment with CO₂ laser blepharoplasty

Bechara FG, Jansen T, Losch R, Altmeyer P, Hoffmann K. J Dermatol 2004; 31: 113–5.

CO₂ laser blepharoplasty led to good cosmetic results and reduced visual impairment.

Chronic eyelid lymphedema and acne rosacea. Report of two cases

Bernardini FP, Kersten RC, Khouri LM, Moin M, Kulwin DR, Mutasin DF. Ophthalmology 2000; 107: 2220–3.

Surgical debulking of the affected soft tissue resulted in very satisfactory cosmetic and functional improvement in both patients.

Ocular rosacea

Ocular involvement in rosacea is very common and may even be seen in isolation or before the onset of cutaneous features. Many patients complain simply of “dry eyes,” often a manifestation of meibomian gland dysfunction. Reduced meibomian lipid secretion is thought to result in rapid evaporation of the aqueous component of the tear film. Additional symptoms are related to the occurrence of blepharitis, episcleritis, chalazion, or hordeolum. Rosacea keratitis can be a serious complication and may occur in adults and children. Severe or refractory cases of ocular disease require specialist ophthalmologic supervision. Particular care is required if systemic retinoids are to be used for inflammatory rosacea when ocular features are present, as retinoids impair meibomian gland secretion.

First-Line Therapies

• “Artificial tears” and lubricants (e.g. phospholipid liposomal eye sprays, carbomers, liquid paraffin, hypromellose)	B
• Warm compresses	B
• Eyelid cleansing/hygiene	B
• Oral tetracyclines	A
• Topical ciclosporin	A
• Topical antibiotics	C
• Omega-3 fatty acid supplementation	A
• <i>H. pylori</i> eradication	D
• Ondansetron	E

Meibomian gland dysfunction: report of the subcommittee on management and treatment of meibomian gland dysfunction

Geerling G, Tauber J, Baudouin C, Goto E, Matsumoto Y, O'Brien T, et al. Invest Ophthalmol Vis Sci 2011; 52: 2050–64.

This is a helpful review of current practice and the evidence base supporting it. A wide range of artificial tears and lubricants (eye drops, sprays, and ointments) are employed. More viscous compounds may be more effective, but less well tolerated due to visual disturbance. Warm compresses are commonly recommended but poorly standardized. Mechanical lid hygiene (scrubs, mechanical expression of meibomian glands, cleansing of the eyelashes and lid margins with various solutions, eyelid massage) is often recommended in conjunction with warming. Commonly used topical antibiotics include bacitracin, fusidic acid, metronidazole, fluoroquinolones, and macrolides. Some of these may act through antiinflammatory properties. Scrubs with tea tree oil and tea tree shampoo have been reported as beneficial, possibly by reducing *Demodex* infestation. Systemic tetracyclines may reduce bacterial colonization, but also exert antiinflammatory effects, including suppression of microbial lipases, which release deleterious free fatty acids. Topical and intralesional corticosteroids can be useful for acute inflammatory episodes, but carry significant risks if use is prolonged. Topical ciclosporin appears to be helpful, but takes 2 months or more to obtain optimal benefit. The authors provide a useful treatment algorithm.

Comparative investigation of treatments for evaporative dry eye

Khairuddin R, Schmidt KG. Klin Monbl Augenheilkd 2010; 227: 128–34.

A randomized, controlled trial with 216 subjects of 3 months' duration. A liposomal phospholipid spray was superior to hyaluronate artificial tears, producing double the increase in tear film break-up time.

Comparative study of treatment of the dry eye syndrome due to disturbances of the tear film lipid layer with lipid-containing tear substitutes

Dausch D, Lee S, Dausch S, Kim JC, Schwert G, Michelson W. Klin Monbl Augenheilkd 2006; 223: 974–83.

A crossover study on 74 subjects with 6-week treatment periods

comparing an eye gel containing triglycerides with a liposomal phospholipid eye spray. Seventy-five percent of the patients favored the spray. Eyelid inflammation and tear film breakup time were also improved more by the liposomal spray.

Oxytetracycline in the treatment of ocular rosacea: a double-blind trial

Bartholomew RS, Reid BJ, Cheesbrough MJ, Macdonald M, Galloway NR. Br J Ophthalmol 1982; 66: 386–8.

Thirty-five patients were investigated in a trial of systemic oxytetracycline, 250 mg twice daily for 6 weeks. Oxytetracycline produced a significantly higher number of remissions than placebo.

Efficacy of doxycycline and tetracycline in ocular rosacea

Frucht-Pery J, Sagi E, Hemo I, Ever-Hadani P. Am J Ophthalmol 1993; 116: 88–92.

Twenty-four patients were randomized to receive doxycycline 100 mg/day or tetracycline 1 g/day. Both groups improved. At 6 weeks all patients except one had symptomatic improvement.

Treatment of ocular rosacea: comparative study of topical ciclosporin and oral doxycycline

Arman A, Demirseren DD, Takmaz T. Int J Ophthalmol 2015; 8: 544–9.

Thirty-eight patients with rosacea-associated eyelid and ocular surface changes and dry eye complaints were randomized to receive 3 months' topical ciclosporin twice daily or oral doxycycline 100 mg twice daily for 1 month, then once daily for 2 months. Both drugs were found to be effective on rosacea-associated ocular changes. ciclosporin was more effective in symptomatic relief and in the treatment of eyelid signs ($p = 0.01$). There was a statistically significant increase in the mean Schirmer score and tear breakup time scores in the ciclosporin group compared with the doxycycline group ($p < 0.05$). The authors conclude that ciclosporin is more effective in ocular rosacea complications and avoids long-term side effects of doxycycline, such as gastrointestinal upset and photosensitivity.

Efficacy of topical ciclosporin for the treatment of ocular rosacea

Schechter BA, Katz RS, Friedman LS. Adv Ther 2009; 26: 651–9.

A double-masked, randomized, 3-month clinical trial on 37 patients comparing twice-daily instillation of ciclosporin ophthalmic emulsion

0.05% with an artificial tear solution. There was significant improvement relative to the control in objective parameters (Schirmer scores, tear breakup time, corneal staining) and quality of life (Ocular Surface Disease Index).

Placebo controlled trial of fusidic acid gel and oxytetracycline for recurrent blepharitis and rosacea

Seal DV, Wright P, Ficker L, Hagan K, Troski M, Menden P. Br J Ophthalmol 1995; 79: 42–5.

Seventy-five percent of patients with blepharitis and associated rosacea were symptomatically improved by fusidic acid gel and 50% by oxytetracycline, but fewer (35%) appeared to benefit from combined treatment.

A randomized controlled trial of omega 3 fatty acids in rosacea patients with dry eye symptoms

Bhargava R, Chandra M, Bansal U, Singh D, Ranjan S, Sharma S. Curr Eye Res 2016; 6: 1–7.

One hundred and thirty patients were treated with the omega-3 fatty acid (O3FA) supplement or placebo (olive oil) for 6 months. Symptoms, Schirmer test, and tear film breakup time improved significantly on O3FA compared with placebo.

Ocular rosacea and treatment of symptomatic *Helicobacter pylori* infection: a case series

Dakovic Z, Vesic S, Vukovic J, Milenkovic S, Jankovic-Terzic K, Dukic S, et al. Acta Dermatovenerol Alp Panonica Adriat 2007; 16: 83–6.

Ocular disease responded better than cutaneous rosacea to eradication of *H. pylori* in this series of seven patients.

The response of erythematous rosacea to ondansetron

Wollina U. Br J Dermatol 1999; 140: 561–2.

Two cases of resistant rosacea responded to the serotonin receptor antagonist ondansetron. This drug is used mainly as an antiemetic during chemotherapy. It was initially given intravenously at a dose of 12 mg daily and later orally at doses of 4 to 8 mg twice daily. Erythema and also ocular symptoms improved.

Rosacea fulminans

Rosacea fulminans (pyoderma faciale) is a very severe facial eruption of sudden onset with prominent pustulation and abscess formation. In addition to conventional treatment modalities for rosacea, a short course of systemic steroids is often indicated to reduce the acute inflammation. Isotretinoin seems to be useful in this condition.

First-Line Therapies

• Systemic corticosteroids	C
• Topical corticosteroids	D
• Isotretinoin	C
• Systemic antibiotics	C

Pyoderma faciale: a review and report of 20 additional cases: is it rosacea?

Plewig G, Jansen T, Kligman AM. Arch Dermatol 1992; 128: 1611–7.

Ten of these 20 patients were hospitalized to commence treatment. Prednisolone was commenced at 1 mg/kg/day for 1 to 2 weeks before adding isotretinoin 0.2 to 0.5 mg/kg/day. The corticosteroid was then tapered off over 2 to 3 weeks and the isotretinoin continued for 3 to 4 months.

Treatment of rosacea fulminans with isotretinoin and topical alclometasone dipropionate

Veraldi S, Scarabelli G, Rizzitelli G, Caputo R. Eur J Dermatol 1996; 6: 94–6.

Five cases were treated successfully with this combination. Alclometasone dipropionate cream (a moderate-potency corticosteroid) was applied twice daily for 10 days then daily for 10 days. The initial dose of isotretinoin was 0.5 mg/kg/day for 1 month followed by 0.7 mg/kg/day for 3 months. Combined cyproterone

acetate/ethinylestradiol was used as a contraceptive. Marked improvement was observed after a month and complete resolution after 4 months.

Pyoderma faciale: a clinical study of 29 patients

Massa MC, Su WP. J Am Acad Dermatol 1982; 6: 84–91.

Thirteen of these patients were hospitalized. All were treated with antibiotics, most frequently tetracycline, minocycline, or erythromycin. Vleminckx packs (containing sulfur, calcium polysulfide, and calcium thiosulfate) were used for 21 cases and were considered the most effective topical treatment. Other modalities employed included benzoyl peroxide and UVB.

Sarcoidosis

Niraj Butala, Brittany Scarpato, and Warren R. Heymann

Sarcoidosis is a multisystem disease of unknown etiology characterized histologically by noncaseating granulomas. It is considered to be immune mediated, with a Th1-predominant cytokine profile. Skin manifestations are observed in approximately 25% of cases. Sarcoidosis has been reported to develop after exposure to inorganic particles in the environment. The use of polymerase chain

reaction (PCR) techniques has also led to the identification of mycobacterial and propionibacterial DNA and RNA in sarcoidal tissue. Sarcoidosis may be the end result of immune responses to those or other specific triggers. Therapy for erythema nodosum associated with sarcoidosis is addressed in the chapter on erythema nodosum.

Management Strategy

The treatment of cutaneous sarcoidosis depends on the types and extent of lesions present and is directed at suppressing the formation of granulomas. Guidelines for treating extracutaneous involvement can be found elsewhere, but it should be recognized that therapy for internal involvement may take precedence over skin disease and that response to treatment may be variable, depending on the type of tissue involved.

In small papular or extremely localized sarcoidosis, treatment with *potent topical corticosteroids* or *intralesional triamcinolone acetonide* (3.3–10 mg/mL) is reasonable. If this is ineffective or involvement is more diffuse, *oral chloroquine* (up to 3.5 mg/kg/day) or *hydroxychloroquine* (up to 6.5 mg/kg/day), methotrexate, or tetracyclines may be effective. If no response is seen or disfiguring lesions are present, *oral prednisone* can be used at a dose of 1 mg/kg daily (maximum 60 mg) for up to 3 months and then tapered if improvement or a stable level is reached, to a maintenance dose of 5 to 10 mg on alternate days for several months. Periodic escalations in dose are necessary with flares of the disease.

Methotrexate may be used as a corticosteroid-sparing agent or as monotherapy in those patients with lupus pernio, ulcerative sarcoidosis, or severe disease that has not responded to prednisone. Initial doses of 15 to 20 mg weekly are favored. *Mycophenolate mofetil* has also shown promise as a steroid-sparing agent. *Thalidomide*, *azathioprine*, *chlorambucil*, *isotretinoin*, or *allopurinol* could be considered if methotrexate or mycophenolate mofetil fails in this subset of patients. Azathioprine and chlorambucil are better studied in patients with pulmonary sarcoidosis. Thalidomide seems to be more effective than isotretinoin and allopurinol in cutaneous disease. Reported failures are described with etretinate and allopurinol.

Biologic agents that inhibit tumor necrosis factor (TNF)- α are therapeutic modalities that should be considered in patients with

lupus pernio or cutaneous sarcoidosis recalcitrant to systemic steroids or steroid-sparing agents. *Infliximab* may be more effective than *adalimumab* but may be associated with a higher rate of infection and autoimmune disease. Etanercept does not appear to be useful for the treatment of sarcoidosis; indeed, some studies have reported on its potential role in patients developing sarcoidosis or in relapse of preexisting sarcoidosis.

Leflunomide and *apremilast* have shown promise in the treatment of cutaneous sarcoidosis unresponsive to other therapies, but further studies are needed to establish long-term usefulness.

Localized disease that does not respond to topical or intralesional corticosteroids, or in those cases in which the use of systemic antimalarial drugs or corticosteroids is undesirable, may represent a niche for other modalities, such as *excision*, *laser*, *photodynamic therapy*, *PUVA*, *surgery* (lupus pernio), or *intralesional chloroquine*.

Specific Investigations

- Special stains, cultures, and polarization of biopsy specimens
- Electrolytes, blood urea nitrogen, creatinine, serum calcium, liver function tests, complete blood count, 24-hour urine calcium, and serum angiotensin-converting enzyme
- Ophthalmologic evaluation, including slit-lamp examination
- Chest radiograph, pulmonary function tests
- Electrocardiogram
- FDG PET (18-fluoro-deoxyglucose positron-emission tomography) is useful in identifying sites for diagnostic biopsy (for patients without apparent lung involvement)
- MRI with gadolinium (neurologic sarcoidosis may occur without any other internal organ involvement)
- DEXA (dual x-ray absorptiometry) bone density scans in patients on long-term oral corticosteroids

Cutaneous sarcoidosis

Wanat KA, Rosenbach M. Clin Chest Med 2015; 36: 685–702.

A thorough review of the literature that discusses advances in the diagnosis and treatment of sarcoidosis and the challenges that clinicians may encounter.

Sarcoidosis: a comprehensive review and update for the dermatologist – part I. Cutaneous disease

Haimovic BA, Sanchez M, Judson MA, Prytowsky S. J Am Acad Dermatol 2012; 66: 699, e1–18.

An extensive review of cutaneous sarcoid, including epidemiology, pathogenesis including the Th1 pathway, morphologies, and treatment. The discussion includes a proposed treatment algorithm.

First-Line Therapies

• Topical corticosteroids	C
• Intralesional corticosteroids	C
• Oral corticosteroids	C
• Chloroquine	B
• Hydroxychloroquine	C
• Methotrexate	B

Verrucous cutaneous sarcoidosis in an adolescent with dark skin

Corradin MT, Forcione M, Fiorentino R, Bordignon M, Alaibac M, Belloni-Fortina A. Eur J Dermatol 2010; 20: 659–60.

A 16-year-old African boy presented with violaceous, verrucous nodules on his forehead, right pectoral region, right arm, and left elbow. The patient was treated with topical mometasone furoate 0.1% cream daily with clearance of lesions in 3 weeks.

Potent topical corticosteroid use is reported to be of some value in anecdotal reports. Most authors believe that intralesional corticosteroids are more effective, yet this, too, is anecdotal. Small lesions are optimal

candidates; however, lupus pernio has also been reported to respond.

A case of scar sarcoidosis of the eyelid

Kim YJ, Kim YD. Korean J Ophthalmol 2006; 20: 238–40.

A 29-year-old man presented with cutaneous sarcoid on his right eyelid. The patient had no other findings of systemic sarcoidosis. A total of 0.6 mL of intralesional triamcinolone 40 mg/mL was injected at 1-cm intervals along the eyelid. Dramatic improvement of the lesion had occurred when he returned for his 1-month follow-up: he received an additional 1 mL of triamcinolone at the same site, which resolved the lesion completely.

Anecdotal reports suggest small, papular sarcoid responds best. The strength of triamcinolone acetonide varies from 2 to 40 mg/mL, and frequency varies from weekly to monthly.

Evidence-based therapy for cutaneous sarcoidosis

Baughman RP, Lower EE. Clin Dermatol 2007; 25: 334–40.

Whereas the recommended starting dose of prednisone for pulmonary sarcoidosis is suggested to be 20 to 40 mg daily, the dose and duration of treatment for cutaneous sarcoidosis have not been established. The authors suggest using this as a benchmark and tapering the steroid dose after 1 or 2 months to one that controls the disease while avoiding toxicity. The authors report that the need for long-term systemic corticosteroids for treatment of chronic sarcoidosis occurs in about a quarter of patients.

Another suggested regimen for prednisone in cutaneous sarcoidosis is 30 mg orally on alternate days until the granulomas fade. The dose is then tapered over several months to 15 mg orally on alternate days. Other protocols report a good response with prednisone 30 to 40 mg orally daily, with a gradual taper to 10 to 20 mg orally on alternate days for 1 year, or prednisone 1 mg/kg orally daily (maximum 60 mg) for 8 to 12 weeks, with a taper to 0.25 mg/kg daily continued for 6 months.

With long-term treatment, prevention of corticosteroid-induced osteoporosis with bisphosphonates and Pneumocystis pneumonia prophylaxis with trimethoprim–sulfamethoxazole should be considered.

Treatment of cutaneous sarcoidosis with chloroquine: review of the literature

Zic JA, Horowitz DH, Arzubiaga C, King LE. Arch Dermatol 1991; 127: 1034–40.

A review of the efficacy and safety of chloroquine in the treatment of cutaneous sarcoidosis. The article cites four studies (three open clinical trials and one case series) that support the use of chloroquine. The authors recommend an initial dose of 250 mg twice daily for 14 days, then 250 mg daily for long-term suppression, though most studies have used 500 mg daily for several months. Relapses after discontinuation of treatment are frequent.

Hydroxychloroquine is effective therapy for control of cutaneous sarcoidal granulomas

Jones EJ, Callen JP. J Am Acad Dermatol 1990; 23: 487–9.

Seventeen patients were treated with 200 mg or 400 mg daily of hydroxychloroquine. Cutaneous lesions regressed in 12 patients within 4 to 12 weeks, and 3 patients had a partial response. Of the 12 patients with the best response, 6 had a recurrence after a dosage reduction or discontinuation.

Hydroxychloroquine may have a better safety profile than chloroquine; however, chloroquine has been better studied in sarcoidosis. Although retinal toxicity is rare, in order to prevent this complication, doses of chloroquine should not exceed 3.5 mg/kg/day, and hydroxychloroquine should not exceed 6.5 mg/kg/day.

Methotrexate is steroid sparing in acute sarcoidosis: results of a double blind, randomized trial

Baughman RP, Winget DB, Lower EE. Sarcoidosis Vasc Diffuse Lung Dis 2000; 17: 60–6.

Twenty-four patients with new-onset symptomatic pulmonary disease were randomized to receive either methotrexate or placebo in addition to their prednisone. Although only 15 patients received at least 6 months of therapy, the methotrexate group required less prednisone than the placebo group. There was no difference in toxicity between the methotrexate and the placebo groups.

A favorable response is usually expected after several months of therapy, and the dose can be tapered weekly after 4 to 6 months. Some studies indicate that methotrexate may be particularly useful for those with ulcerative sarcoidosis.

Prolonged use of methotrexate for sarcoidosis

Lower EE, Baughman RP. Arch Intern Med 1995; 155: 846–51.

Fifty patients were treated with methotrexate, 10 mg weekly, for a

minimum of 2 years. Most patients did not have cutaneous involvement, but in those who did a good response was seen. In many patients methotrexate was used in conjunction with prednisone with favorable results.

Second-Line Therapies

• Mycophenolate mofetil	D
• Infliximab	B
• Minocycline, doxycycline	D

Mycophenolate mofetil may serve as a steroid-sparing agent for sarcoidosis

Kouba DJ, Mimouni D, Rencic A, Nousari HC. Br J Dermatol 2003; 148: 147–8.

A 53-year-old African American with extensive mucocutaneous disease and pulmonary involvement was recalcitrant to standard first-line treatments. He was given oral treatments with prednisone 60 mg tapered to 5 mg every other day over 5 months, hydroxychloroquine 6 mg/kg daily, and mycophenolate mofetil 45 mg/kg daily for 12 months. Significant improvement was noted at 6 weeks and remained at 18 months follow-up with significant reduction of systemic disease.

Treatment of lupus pernio: the results of 116 treatment courses in 54 patients

Stagaki E, Mountford WK, Lackland DT, Judson MA. Chest 2009; 135: 468–76.

This retrospective study of 54 patients with cutaneous sarcoid undergoing 116 treatment regimens showed infliximab-containing regimens to have a high likelihood of complete or near-complete resolution compared with those containing corticosteroids, methotrexate, and hydroxychloroquine. Additionally, when systemic

steroids were combined with a second agent there was a significant reduction in prednisone dose requirement.

Infliximab has become a second-line agent, particularly in cases of lupus pernio and neurocutaneous lupus. Studies suggest that infliximab can be used as an induction agent with long-term methotrexate. Superiority to etanercept has been demonstrated.

Recently a double-blind randomized trial for treatment of ocular sarcoidosis with etanercept showed no comparative improvement in the sarcoidal lesions. Also, sarcoidosis was reported to develop in a patient with ankylosing spondylitis after being treated with etanercept. Therefore etanercept does not appear to be useful for the treatment of sarcoidosis.

Infliximab for chronic cutaneous sarcoidosis: a subset analysis from a double-blind randomized clinical trial

Baughman RP, Judson MA, Lower EE, Drent M, Costabel U, Flavin S, et al. Sarcoidosis Vasc Diffuse Lung Dis 2016; 32: 289–95.

A subset analysis of 17 patients with chronic cutaneous sarcoidosis from a larger study of 138 patients with pulmonary disease reviewed their response to infliximab (3 or 5 mg/kg) versus placebo over 24 weeks. The Sarcoidosis Activity and Severity Index (SASI) scoring system found significant improvement in desquamation and induration at week 24, but erythema, percentage of area involved, and evaluation of paired photographs did not show a significant difference.

Infliximab, although effective, has been shown to increase the risk of tuberculosis reactivation, the risk of other granulomatous infections, lymphomas, and autoimmune disease. Therapy is expensive, costing up to thousands of dollars per infusion. One must be aware of the side effects and cost.

The use of tetracyclines for the treatment of sarcoidosis

Bachelez H, Senet P, Cadranel J, Kaoukhov A, Dubertret L. Arch Dermatol 2001; 137: 69–73.

Twelve patients with cutaneous sarcoidosis, three of whom had systemic involvement, were treated with minocycline at a daily dose of 200 mg orally for a median duration of 12 months. Ten patients showed a response, eight complete and two partial; one patient's symptoms remained stable and one patient's disease progressed. Four patients experienced relapse after discontinuation of minocycline; doxycycline was then utilized, resulting in remission.

Due to the safety profile and moderate success, tetracyclines can be considered a second-line therapy in limited cutaneous disease.

Third-Line Therapies

• Thalidomide	D
• Allopurinol	D
• Isotretinoin	E
• Azathioprine	E
• Chlorambucil	B
• Quinacrine	D
• Topical tacrolimus	E
• Intralesional chloroquine	E
• Excision	D
• Laser	E
• Melatonin	D
• Pentoxifylline	E
• Apremilast	C
• Leflunomide	D
• Adalimumab	E
• Medium-dose ultraviolet A1 (UVA1)	E
• PUVA	D
• Photodynamic therapy	D
• Dapsone	E
• Intralesional 5-fluorouracil	E

Treatment of cutaneous sarcoidosis with thalidomide

Nguyen YT, Dupuy A, Cordoliani F, Vignon-Pennamen MD, Lebbé C, Morel P, et al. J Am Acad Dermatol 2004; 50: 235–41.

A retrospective evaluation of 12 patients with cutaneous sarcoidosis, 2 with systemic involvement and 10 of whom were treated successfully with a treatment duration of 2 to more than 16 months, with a daily dose of thalidomide ranging from 50 to 200 mg orally daily. Two patients received combined therapy with oral corticosteroids (dose ranging from 7.5–30 mg daily), one patient used potent topical corticosteroids, and one received combined therapy with methotrexate (dose 25 mg weekly). The average response time was 2 to 3 months. The main adverse effect noted in this series was deep venous thrombosis in one patient.

A case of cutaneous acral sarcoidosis with response to allopurinol

Antony F, Layton AM. Br J Dermatol 2000; 142: 1052–3.

A 38-year-old Afro-Caribbean man with painful sarcoidal nodules around the ends of his fingers (but no evidence of sarcoidal arthritis) had a partial response to oral and intralesional steroids with subsequent recurrence of his lesions. He had no improvement with hydroxychloroquine, methotrexate, or azathioprine. He was started on allopurinol 100 mg twice daily, which was increased to 300 mg daily after 3 weeks. This resulted in sustained objective clinical improvement.

A few case reports demonstrate resolution of truncal and extremity plaques of sarcoidosis after 12 weeks of allopurinol.

Cutaneous sarcoidosis: complete remission after oral isotretinoin therapy

Georgiou S, Monastirli A, Pasmatzis E, Tsambaos D. Acta Derm Venereol 1998; 78: 457–9.

A 31-year-old woman with nodules and plaques on the trunk and extremities showed a complete remission with 8 months of isotretinoin at 1 mg/kg daily; 15-month follow-up revealed continuing remission.

Two other cases report improvement with a 30-week course (0.67–1.34 mg/kg daily) and a 6-month course (0.4–1 mg/kg daily), respectively, of

isotretinoin.

Long-term use of azathioprine as a steroid-sparing treatment

Hof DG, Hof PC, Godfrey WA. Am J Respir Crit Care Med 1996; 153: 870A.

Of the 21 patients in this study, 8 had “multisystem” involvement and 1 had skin-only involvement. All patients with extrapulmonary disease achieved a complete remission with azathioprine and a tapering dose of prednisone.

Chlorambucil treatment of sarcoidosis

Israel HL, McComb BL. Sarcoidosis 1991; 8: 35–41.

In this study, 31 patients received chlorambucil, either because complicating diseases prevented them from receiving corticosteroids or they did not respond to them. Marked improvement was noted in 15 patients and moderate improvement in 13 patients, but relapses were very common upon discontinuation. No immune suppression–related side effects were noted.

Scar sarcoidosis following tattooing of the lips treated with mepacrine

Yesudian PD, Azurdia RM. Clin Exp Dermatol 2004; 29: 552–4.

A 50-year-old woman with disfiguring scar sarcoidosis of the lips responded poorly to steroids and was unable to tolerate hydroxychloroquine; she was started on mepacrine 100 mg daily with significant remission to practically normal lip margins. She has had no flares in 10 months of follow-up visits.

The yellow discoloration of the skin and sclera observed with quinacrine (one third of patients) makes chloroquine and hydroxychloroquine better alternatives.

Successful treatment of recalcitrant cutaneous sarcoidosis with fumaric acid esters

Nowack U, Gambichler T, Hanefeld C, Kastner U, Altmeyer P. BMC Dermatol 2002; 24: 215.

Report of three patients with cutaneous sarcoidosis treated with fumaric acid esters for 4 to 12 months, resulting in complete clearance of cutaneous lesions.

Lichenoid type of cutaneous sarcoidosis: great response to

topical tacrolimus

Vano-Galvan S, Fernandez-Guarino M, Carmona LP, Harto A, Carrillo R, Jaen P. Eur J Dermatol 2008; 18: 89–90.

A 33-year-old female with lichenoid-type cutaneous sarcoidosis was treated with 0.1% tacrolimus ointment twice daily. Near-complete resolution was noted at 2 months, and the patient remained free of disease at 4 months.

Topical pimecrolimus as a new optional treatment in cutaneous sarcoidosis of lichenoid type

Tammaro A, Abruzzese C, Narcisi A, Cortesi G, Parisella FR, DiRusso PP, et al. Case Rep Dermatol Med 2014; 2014: 976851.

A 66-year-old woman with violaceous, lichenoid sarcoidosis previously unresponsive to clobetasol resolved with topical tacrolimus.

Intralesional chloroquine for the treatment of cutaneous sarcoidosis

Liedtka JE. Int J Dermatol 1996; 35: 682–3.

Multiple injections of intralesional chloroquine hydrochloride (50 mg/mL) were effective in treating five lesions in a single patient, with minimal side effects.

Cutaneous nasal sarcoidosis: treatment by excision and split-skin grafting

Goldin JH, Jawad SMA, Reis AP. J Laryngol Otol 1983; 97: 1053–6.

Split-thickness and full-thickness skin grafts, dermabrasion, and primary closure have been attempted, with mixed results. Surgery has been used in ulcerative and nonulcerative sarcoidosis.

Several recent reports utilizing primary closure, a paramedian forehead flap, and a full-thickness graft continue to show mixed long-term results.

CO₂ laser vaporization for disfiguring lupus pernio

Young HS, Chalmers RJ, Griffiths CE, August PJ. J Cosmet Laser Ther 2002; 4: 87–90.

CO₂ laser resurfacing was used in two patients with lupus pernio with a favorable cosmetic result.

Flashlamp pulsed dye laser and Q-switched ruby laser were beneficial in one case report of lupus pernio. However, exacerbations of lupus pernio—

namely, generalized ulceration in treated and untreated lesions—have been reported after this therapy.

Scar sarcoidosis in a child: case report of successful treatment with the pulsed dye laser

Holzmann RD, Astner S, Forschner T, Sterry G. *Dermatol Surg* 2008; 34: 393–6.

A 10-year-old boy with a 1-cm lesion of varicella zoster–induced scar sarcoidosis on the left cheek had not responded to systemic antibiotics or systemic steroids. Clinical remission occurred after three pulsed dye laser treatments at 6-week intervals, which consisted of two to four pulses using a 595-nm wavelength and a 0.5-ms pulse duration. At 12 months' follow-up there was no evidence of recurrence, although the varicella scar became more visible once the sarcoidosis disappeared.

Successful treatment of cutaneous sarcoidosis lesions with the flashlamp pumped pulsed dye laser: a case report

Roos S, Raulin C, Ockenfels H, Karsai S. *Dermatol Surg* 2009; 35: 1139–40.

A 63-year-old Caucasian female with nodular sarcoid on her back was treated with flashlamp pumped pulsed dye laser at 6 J/cm² (585 nm, 0.5 ms, 12 mm) with complete resolution in 4 weeks. Prednisone was utilized for iridocyclitis after the laser treatments were completed. She remained clear 13 months after discontinuation of systemic steroids.

Melatonin is a safe and effective treatment for chronic pulmonary and extrapulmonary sarcoidosis

Pignone AM, Rosso AD, Fiori G, Matucci-Cerinic M, Becucci A, Tempestini A, et al. *J Pineal Res* 2006; 41: 95–100.

Melatonin was given to 18 chronic sarcoid patients for 2 years at a dose of 20 mg/day during the first year and 10 mg/day during the second year. Skin lesions, present in three patients, completely disappeared after 24 months of treatment. No side effects were reported.

Melatonin may increase drowsiness and has been associated with hypothermia, hypotension, and bradycardia.

Efficacy and safety of apremilast in chronic cutaneous

sarcoidosis

Baughman RP, Judson MA, Ingledue R, Craft NL, Lower EE. Arch Dermatol 2012; 148: 262–4.

A study of 15 patients on systemic steroids treated with 20 mg twice-daily (once daily if not tolerated) apremilast (a novel phosphodiesterase type 4 inhibitor). A significant reduction in SASI induration score was observed at 4 and 12 weeks. Relapse was noted in three patients at the 3-month follow-up. Pentoxifylline has been reported as an effective treatment for pulmonary sarcoidosis; however, efficacy in cutaneous sarcoidosis needs further investigation.

Leflunomide for chronic sarcoidosis

Baughman RP, Lower EE. Sarcoidosis Vasc Diffuse Lung Dis 2004; 21: 43–8.

In a case series study, 32 patients with sarcoidosis involving the eye, lung, and/or skin were treated with leflunomide. Remission (complete and partial) was seen in 12 of 17 patients treated with leflunomide and 13 of 15 patients treated with leflunomide and methotrexate. An initial dose of leflunomide 100 mg/day for 3 days was followed by 20 mg daily after that.

Adverse events, including gastrointestinal problems, and hypersensitivity reactions, including erythema multiforme and Stevens–Johnson syndrome, have been reported.

Adalimumab for treatment of cutaneous sarcoidosis

Heffernan MP, Smith DI. Arch Dermatol 2006; 142: 17–9.

A 46-year-old black woman with sarcoid papules on the nose and ulcerating nodules on the legs had failed local therapy with topical clobetasol and intralesional triamcinolone, hydroxychloroquine, and pentoxifylline. She did not tolerate minocycline. Adalimumab was administered at a dose of 40 mg subcutaneously once weekly. After 10 weeks the nodules on her legs were completely healed and the lesions on her nose were significantly improved.

According to Au et al. (Adalimumab induced subcutaneous nodular sarcoidosis: a rare side effect of tumor necrosis factor- α inhibitor. Sarcoidosis Vasc Diffuse Lung Dis 2014; 31: 249–51), “Adalimumab and other tumor necrosis factor- α inhibitors have been shown in the recent years to successfully treat sarcoidosis refractory to systemic corticosteroids and other agents. However, there have been an increasing number of cases of

sarcoidosis paradoxically induced by these agents. It is hypothesized that this is due to the disruption of the fine balance of cytokines involved in granuloma formation."

Cutaneous sarcoidosis treated with medium-dose UVA1

Mahnke N, Medve-Koenigs K, Berneburg M, Ruzicka T, Neumann NJ. J Am Acad Dermatol 2004; 50: 978–9.

An 82-year-old woman with cutaneous sarcoidosis affecting 80% of her body surface was treated with medium-dose UVA1 radiation four times weekly. She received 20 J/cm² for the first three treatment sessions, 40 J/cm² for the next 12 sessions, and then 60 J/cm² for the next 35 sessions. After 50 sessions, nearly all lesions had resolved.

Treatment of cutaneous sarcoid with topical gel psoralen and ultraviolet A

Gleeson CM, Morar N, Staveley I, Bunker CB. Br J Dermatol 2011; 164: 892–4.

A series of six patients with recalcitrant cutaneous sarcoidosis were treated with topical gel psoralen and UVA twice weekly at 0.2 J/cm². Patients were placed on oral prednisolone; five patients were tapered at the start of therapy, and one remained on long-term oral prednisolone. In follow-up at 4 months to 3 years, three patients had complete resolution, and three patients had greater than 50% improvement.

Photodynamic therapy for the treatment of cutaneous sarcoidosis

Penrose C, Mercer SE, Shim-Chang H. J Am Acad Dermatol 2011; 65: e12–4.

A 52-year-old African American female with topical and systemic steroid-resistant cutaneous sarcoidosis (likely lupus pernio) had significant improvement after 10 sessions of aminolevulinic acid and photodynamic therapy at 2-week intervals.

Photodynamic therapy utilizing intense pulsed light has also been beneficial in a patient with facial cutaneous sarcoidosis (Hasegawa T, Suga Y, Mizuno Y, Haruna K, Ikeda S. Photodynamic therapy using intense pulsed light for cutaneous sarcoidosis. J Dermatol 2012; 39: 564–5).

Cutaneous sarcoidosis successfully treated with intralesional 5-fluorouracil

Gharavi N, Diehl J, Soriano T. *Dermatol Surg* 2015; 41: 1082–5.

A 48-year-old Caucasian male with large periorbital sarcoidal nodules significantly improved with three monthly treatments of 0.5 to 1.0 mL of 50 mg/mL of intralesional 5-fluorouracil. The exact mechanism by which 5-fluorouracil resolves granulomas remains unclear.

Resolution of cutaneous sarcoidosis following topical application of *Ganoderma lucidum* (reishi mushroom)

Saylam Kurtipek G, Ataseven A, Kurtipek E, Kucukosmanoglu I, Toksoz MR. *Dermatol Ther (Heidelb)* 2016; 6: 105–9.

Ganoderma lucidum (reishi mushroom) has been used in traditional Chinese and Japanese medicine as an herbal remedy for over 2000 years. Studies have shown that *G. lucidum* has antiallergic, antioxidant, antitumor, antiviral, and antiinflammatory properties. A review of the literature revealed that there were no studies examining the use of *G. lucidum* for the treatment of skin diseases. A 44-year-old male patient who used soap enriched with *G. lucidum* and goat's milk for 3 days to treat annular cutaneous sarcoidosis, showed almost complete regression of the lesions.

Cutaneous sarcoid mimicking tinea imbricata

Reddy R, Vitiello M, Kerdel F. *Int J Dermatol* 2011; 50: 1132–4.

A 67-year-old Hispanic male with biopsy-proven cutaneous sarcoidosis who failed treatment with topical and intralesional steroids, topical tacrolimus, and oral ciclosporin showed improvement after starting oral prednisone and 100 mg dapsone daily.

Sarcoidosis is a great masquerader of other dermatoses. This case affirms the need for both diagnostic suspicion and combination therapy for patients with the disease.

Scabies

James B. Powell, and William F.G. Tucker

Scabies is an intensely pruritic skin condition due to infestation by the obligate skin parasite “itch mite” *Sarcoptes scabiei*. Endemic in many impoverished communities worldwide, with a global prevalence of 300 million, scabies is a common public health concern, especially in less developed countries. Of concern is the emergence of resistance to classical scabicides, meaning that already limited treatment options may be further diminished.

Prevalence of scabies and impetigo worldwide: a systematic review

Romani L, Steer AC, Whitfeld MJ, Kaldor JM. *Lancet Infect Dis* 2015; 15: 960–7.

Scabies and global control of neglected tropical diseases

Currie BJ. *N Engl J Med* 2015; 373: 2371–2.

The literature continues to be littered with cases of delayed diagnosis but unfortunately less so with systematic evidence regarding the efficacy of the multiple treatments used and their safety upon which to base treatment decisions. Multiple small and variable studies (regarding quality, treatment protocols, and measured outcomes) mostly from resource-poor settings have been analyzed in a Cochrane review originally conducted in 1997 with an update in 2007 and BMJ “Clinical Evidence” article by the same authors in 2013. These conclude that topical permethrin is the most effective treatment for scabies (including at reducing itch persistence), with oral ivermectin an effective (although less so than topical permethrin) oral alternative. This means that when considering treatment options apart from permethrin, the safety, side effects, and cost of such treatments should be strongly considered.

Management Strategy

Suspicion is the prerequisite for disease control, with scabies infestation coming to mind in any case of (unexplained) pruritus. Initial treatment failure should be expected, especially in heavy infestation and crusted scabies. Treatments may need to be repeated on a number of occasions and even combined. No agent seems greatly effective against the inflammatory skin reaction, and the difference between postscabetic itch and ongoing infestation can be difficult to decipher.

It is generally accepted that the face and scalp do not need treatment except in infants and the immunocompromised individual: topicals are therefore usually applied from the neck down. Reservoirs of infestation include the subungual areas, which must therefore be addressed when applying topical therapy. What is essential is that all intimates of the patient, whether apparently affected or not, are treated at about the same time. Many clinicians find an explanatory

leaflet helpful, detailing exactly how to apply a prescribed antiscabetic and also the need to launder clothes and bedding. The skills and patience of the physician are often rigorously tested throughout this process!

Oral *ivermectin* in single doses of 200 µg/kg has been shown to be very effective in a number of studies, although it is not more effective than properly applied *permethrin*. It is unlicensed for this indication in humans but is used in animal “mange” and is widely and safely used in onchocerciasis. Its safety in children under 15 kg in weight is unknown. Oral ivermectin should therefore be reserved for when appropriate application of a topical antiscabetic is not possible or practicable—for example, compliance, severe eczematization, or as a part of a treatment regimen in crusted/hyperkeratotic and resistant cases. However, randomized controlled trials examining oral ivermectin in crusted scabies are lacking. Treatment with permethrin is repeated after 1 week, as it may not be effective against scabies mite eggs. This repeat treatment allows time for any such eggs not destroyed by the first treatment to hatch so the hatchlings may then be killed. Similarly oral ivermectin may not be effective against the ova, hence the reason why repeat dosing is often needed in practice and shows improved cure rates in studies.

Regarding other topical treatments, controversy exists in the literature over *lindane*, an organochloride insecticide, regarding safety and specifically neurotoxicity—hence, its demotion here to third-line therapies. In many settings its use need not be considered as other more or equally effective treatment options will be available. However, due to its low cost (and efficacy), lindane is still used in some countries. *Crotamiton* 10% is a safe topical antipruritic that may be most useful as an “add-on” therapy, for example, between or after other topical or oral agents where its emollient, antipruritic, and antiscabetic properties can be called into use. *Benzyl benzoate*, although effective, can be very irritating. *Sulfur* is another safe, low-cost (but smelly and also irritating) treatment.

When treating crusted scabies in practice combined topical and oral therapy may have to be considered and repeated to achieve a cure. Additional keratolytic therapy such as *emollients*, *salicylic acid*, and *bathing* may be needed to remove hyperkeratotic plaques, which harbor and protect the mites. There is, however, very little systematic evidence in this area. Recently a report of acitretin being used has emerged.

Specific Investigation

- Visualization of mites and burrows

The one specific investigation for scabies is to isolate the mite and/or its burrow; nothing is more guaranteed to ensure compliance than to show a patient his or her codweller under the bench microscope. These will not be found in all cases, however. Dermatologists take great delight in capturing their quarry, and each will be an advocate of one particular method. With standard scabies, burrows are generally easiest to find around the hands, and the mite can often be seen as a dark dot at one end. Using a dermatoscope to visualize the mite in situ revealing the characteristic triangle or “delta wing” appearance at the mite’s head is a simple and quick way of confirming the diagnosis

Epiluminescence microscopy. A new approach to in vivo detection of *Sarcoptes scabiei*

Argenziano G, Fabbrocini G, Delfino M. Arch Dermatol 1997; 133: 751–73.

With the aid of a blunt needle or sewing pin, the mite can be out and placed on a glass slide. Alternatively, the burrow is carefully scraped or shaved with a 15 Bard–Parker blade, and the slice of stratum corneum placed on a glass slide with some immersion oil. Skin biopsy is often illuminating, particularly as the mite may be a surprise finding.

“Wake sign”: an important clue for the diagnosis of scabies

Yoshizumi J, Harada T. Clin Exp Dermatol 2009; 34: 711–4.

The “wake sign” reported here refers to the scale that may be seen at the edges of scabies burrows, being reminiscent of the “wake” left behind, somewhat momentarily, on the surface of water by an object moving through it (e.g., a ship).

The burrow ink test and the scabies mite

Woodley D, Saurat JH. J Am Acad Dermatol 1981; 4: 715–22.

A fountain pen (or felt-tip pen/surgical marker, if none available) can be used to conduct the “burrow ink test.” A blob of ink is carefully applied to a suspected burrow, left for a minute or so, and

wiped off with an isopropyl alcohol swab. If a burrow is present, then capillary action will have led to tracking of the ink into the burrow, leaving a wiggly line.

Laboratory testing will frequently show a mild eosinophilia in peripheral blood. Serologic investigations may in the future become more accurate and therefore useful in certain cases.

A diagnostic test for scabies: IgE specificity for a recombinant allergen of *Sarcoptes scabiei*

Jayaraj R, Hales B, Viberg L, Pizzuto S, Holt D, Rolland JM, et al. Diagn Microbiol Infect Dis 2011; 71: 403–7.

In this study specific IgE antibodies to a major scabies antigen were measured in 140 plasma samples from currently infested and uninfested (control) subjects. Reported results showed 100% sensitivity and 93.75% specificity.

First-Line Therapies

• Permethrin 5% cream	A
• Oral ivermectin	A

Interventions for treating scabies

Strong M, Johnstone PW. Cochrane Database Syst Rev 2007; 3: CD000320.

A new search for studies and content was performed in 2010, but no changes to the conclusions were made. Authors identified 22 small trials for inclusion (19 from resource-poor countries) containing 2676 patients in total. No herbal or traditional medicine trials were identified for inclusion. Permethrin was identified as the most effective topical treatment for scabies, with ivermectin appearing to be an effective oral treatment.

Scabies

Johnstone PW, Strong M. BMJ Clin Evid 2014; 12: 1707.

In this more recent review of the evidence the authors of the Cochrane review class permethrin as “beneficial”; crotamiton and oral ivermectin as “likely to be beneficial”; and benzyl benzoate, malathion, and sulfur compounds to be of “unknown effectiveness.”

Topical permethrin and oral ivermectin in the management of scabies: a prospective, randomized, double blind controlled study

Sharma R, Singla A. Indian J Dermatol Venereol Leprol 2011; 77: 581–6.

One hundred twenty cases of scabies were included in this study from Delhi, India. Cure rates (“defined as >50% improvement in lesion count and pruritus and negative microscopy”) of around 90% were seen at 4 weeks in those treated with either a single dose of 5% permethrin topically or ivermectin (200 µg/kg/dose) or “double dose regimen repeated at 2 weeks interval.”

The efficacy of oral ivermectin vs. sulfur 10% ointment for the treatment of scabies

Alipour H, Goldust M. Ann Parasitol 2015; 61: 79–84.

This randomized study in Iran compared one dose of oral ivermectin (200 µg/kg) versus sulfur 10% ointment (applied for 3 consecutive days) in 420 patients. Treatment was assessed at 2 and 4 weeks. If there was treatment failure at 2 weeks, treatment was repeated. A single dose of ivermectin provided a cure rate of 61.9% at the 2-week follow-up, which increased to 78.5% at the 4-week follow-up after repeating the treatment. Treatment with sulfur 10% ointment was effective in 45.2% of patients at the 2-week follow-up, which increased to 59.5% at the 4-week follow-up after treatment was repeated.

Tratamiento de la escabiasis con ivermectina por via oral

Macotella-Ruiz E, Pena-Gonzalez G. Gac Med Mex 1993; 129: 201–5.

This randomized trial compared the treatment of 55 patients with a clinical diagnosis of scabies with either a single dose of ivermectin 200 µg/kg or placebo. After 7 days the code was broken because there was such a significant improvement in the treated group: 23 of 29 versus 4 of 26.

A comparative trial of oral ivermectin and topical permethrin in the treatment of scabies

Usha V, Gopalakrishnan Nair TV. J Am Acad Dermatol 2000; 42: 236–40.

In this trial in 88 patients, permethrin came out better for cure at 2 weeks.

Safety of and compliance with community-based ivermectin therapy

Pacque M, Munoz B, Greene BM, White AT, Dukuly Z, Taylor HR. Lancet 1990; 335: 1377–80.

Adverse reactions after large-scale treatment of onchocerciasis with ivermectin: combined results from eight community trials

De Sole G, Remme J, Awadzi K, Accorsi S, Alley ES, Ba O, et al. J WHO 1989; 67: 707–19.

In both studies ivermectin was remarkably well tolerated, even in repeated courses.

Deaths associated with ivermectin treatment of scabies

Barkwell R, Shields S. Lancet 1997; 349: 1144–5.

This is the only “fly in the ointment” with ivermectin: the authors report on the treatment of 47 elderly, mentally disadvantaged residents of an institution with a single dose of ivermectin at 150 to 200 µg/kg body weight. All had failed to respond to multiple earlier courses of lindane and crotamiton. All were cured, but over the next 6 months 15 died from a number of causes, whereas only 5 died in an equivalent matched population within the same unit. Many patients were taking other drugs, raising the possibility of interactions. *The possibility that patients who are debilitated are more susceptible to scabies may have contributed to the increase in deaths in ivermectin-treated individuals.*

Difficult-to-treat scabies: oral ivermectin

National Institute for Health and Care Excellence. March 2014; nice.org.uk/guidance/esuom29.

Randomized controlled trials using oral ivermectin in scabies show either mild side effects (including transient worsening of itch) or report no adverse events.

Second-Line Therapies

• Crotamiton	A
• Topical ivermectin	B
• Malathion 0.5% lotion	B
• Benzyl benzoate	B
• Sulfur	B

Comparison of oral ivermectin versus crotamiton 10% cream in the treatment of scabies

Goldust M, Rezaee E, Raghifar R. Cutan Ocul Toxicol 2014; 33: 333–6.

In this study from Iran 320 patients were randomized to receive a single dose of oral ivermectin 200 µg/kg or crotamiton 10% cream (topically twice daily for 5 consecutive days). Treatment was evaluated at 2 and 4 weeks and repeated if evidence of treatment failure. Ivermectin provided a cure rate of 62.5% at 2 weeks, which increased to 87.5% at the 4-week follow-up after repeating treatment. Treatment with crotamiton was effective in 46.8% of patients at the 2-week follow-up, which increased to 62.5% at the 4-week follow-up after repeating treatment.

Comparison of crotamiton 10% cream (Eurax) and permethrin 5% cream (Elimite) for the treatment of scabies in children

Taplin D, Meinking TL, Chen JA, Sanchez R. Pediatr Dermatol 1990; 7: 67–73.

This double-blind randomized study compared these drugs in children from 2 months to 5 years of age. A single overnight application was used. Cure rates were superior with permethrin at 2

weeks (30% vs. 13%) and at 4 weeks (89% vs. 60%).

A family based study on the treatment of scabies with benzyl benzoate and sulfur ointment

Gulati PV, Singh KP. Indian J Dermatol Venereol Leprol 1978; 44: 269–73.

One hundred fifty-eight clinically diagnosed patients were randomly allocated to use either 25% benzyl benzoate emulsion or 5% sulfur ointment. Treatment was applied at least three times over 24 hours. The sulfur seems to have been marginally more effective.

Treatment of scabies using 8% and 10% topical sulfur ointment in different regimens of application

Sharquie KE, Al-Rawi JR, Noaimi AA, Al-Hassany HM. J Drugs Dermatol 2012; 11: 357–64.

This single-blinded study from Iraq included 97 patients with scabies. Treatment for 3 days (e.g., washing off and reapplying every 24 hours) resulted in over 90% responding to treatment. A once-only application was much less effective but resulted in fewer side effects (irritant dermatitis, mild burning sensation).

Ivermectin versus benzyl benzoate applied once or twice to treat human scabies in Dakar, Senegal: a randomized controlled trial

Fatimata LY, Caumes E, Ndaw CAT, Ndiaye B, Mahe A. Bull WHO 2009; 87: 424–30.

In this study, which excluded those with crusted scabies, topical benzyl benzoate 12.5% was more effective than oral ivermectin in treating scabies infestation.

Comparison of ivermectin and benzyl benzoate for treatment of scabies

Glaziou P, Cartel JL, Alzieu P, Briot C, Moulia-Pelat JP, Martin PM. Trop Med Parasitol 1993; 44: 331–2.

A randomized study in French Polynesia compared a single dose of 100 µg/kg ivermectin with 10% benzyl benzoate lotion applied below the neck and repeated 12 hours later. Both were equally effective.

Treatment of scabies: topical ivermectin vs. permethrin 2.5% cream

Goldust M, Rezaee E, Raghifar R, Hemayat S. Ann Parasitol 2013; 59:

79–84.

In another study from Iran 380 patients with scabies were randomized into two groups: the first received 1% ivermectin topically, the second permethrin 2.5%. Both were applied twice over a week and treatment repeated at 2 weeks if there was evidence of treatment failure. Ivermectin provided a cure rate of 63.1% at the 2-week follow-up, which increased to 84.2% at the 4-week follow-up after repeating the treatment. Permethrin 2.5% was effective in 65.8% of patients at the 2-week follow-up, which increased to 89.5% at the 4-week follow-up.

***Sarcoptes scabiei* infestation treated with malathion liquid**

Hanna NF, Clay JC, Harris JRW. Br J Venereol Dis 1978; 54: 354.

An uncontrolled study using 0.5% malathion liquid in 30 patients, yielding an 83% cure rate at 4 weeks.

Third-Line Therapies

• Lindane	B
• Monosulfiram soap	B
• Natural pyrethrins	B
• Thiabendazole	B
• Tea tree oil	E

Control of scabies by use of soap impregnated with “Tetmosol.”

Gordon RM, Davey TH, Unsworth K, Hellier FF, Parry SC, Alexander JR. Br Med J 1944; 2: 803–6.

A bath a day for 6 days using 20% Tetmosol (monosulfiram) soap cured all six patients; three baths cured 88 of 110 patients; the relapse rate was 20%.

Presumably the limiting factor in wartime Britain was the lack of hot bathwater!

Topically applied thiabendazole in the treatment of scabies

Hernandez-Perez E. Arch Dermatol 1976; 112: 1400–1.

A 10% suspension used to treat 40 patients achieved a “satisfactory response” in 80%.

Efficacy and tolerability of natural synergised pyrethrins in a new thermolabile foam formulation in topical treatment of scabies: a prospective randomized, investigator-blinded, comparative trial vs. permethrin cream

Amerio P, Capizzi R, Milan M. Eur J Dermatol 2003; 13: 69–71.

This trial included 40 patients, and the pyrethrin foam was reported to be “at least as effective” as permethrin.

Efficacy and tolerability of a new synergized pyrethrins thermophobic foam in comparison with benzyl benzoate in the treatment of scabies in convicts: the ISAC study

Biele M, Campori G, Colombo R, De Giorgio G, Frascione P, Sali R, et al; ISAC Investigator Group. J Eur Acad Dermatol Venereol 2006; 20: 717–20.

In this multicenter, randomized, investigator-blinded trial synergized pyrethrins (over 3 consecutive days) and benzyl benzoate (over 5 consecutive days) both achieved a cure rate of over 90% at 4 weeks, but the pyrethrin foam was better tolerated by the convicts.

Therapeutic potential of tea tree oil for scabies

Thomas J, Carson CF, Peterson GM, Walton SF, Hammer KA, Naunton M, et al. Am J Trop Med Hyg 2016; 94: 258–66.

In the face of emerging resistance to ivermectin and permethrin, new cost-effective, safe treatments are needed. Tea tree oil has shown some promising effects, but randomized controlled studies are needed.

Efficacy and safety of a lindane 1% treatment regimen for scabies, confirmed by dermoscopy-guided skin scraping with

microscopic examination

Park SE, Her Y, Kim SS, Kim CW. Clin Exp Dermatol 2015; 40: 611–6.

This retrospective study from Seoul, Korea, evaluated the efficacy of 1% lindane cream in treating microscopically confirmed scabies in 50 cases. Patients were treated with 1% lindane cream twice weekly. The cumulative efficacy of lindane 1% cream was 40% after 1 week, 88% after 2 weeks, and 98% after 3 weeks of treatment.

Comparison of oral ivermectin vs. lindane lotion 1% for the treatment of scabies

Mohebbipour A, Saleh P, Goldust M, Amirnia M, Zadeh YJ, Mohamad RM, et al. Clin Exp Dermatol 2013; 38: 719–23.

In this study from Iran including 148 patients a single dose of oral ivermectin was more effective than two applications of lindane lotion 1% 1 week apart (61% vs. 47%) after 2 weeks. After repeat treatment if evidence of infestation remained at 2 weeks, ivermectin was superior to lindane lotion 1% (89% vs. 73%).

Treatment of scabies: comparison of lindane 1% vs. permethrin 5%

Rezaee E, Goldust M, Alipour H. Skinmed 2015; 13: 283–6.

Superior efficacy for permethrin shown.

Lindane toxicity: a comprehensive review of the medical literature

Nolan K, Kamrath J, Levitt J. Pediatr Rev 2012; 29: 141–6.

This review describes 67 cases of adverse reactions and deaths associated with lindane use, where even “labeled” usage caused 43% of the “serious adverse reactions.”

Treatment of crusted scabies with acitretin

Veraldi S, Nazzaro G, Serini SM. Br J of Dermatol 2015; 173: 862–3.

Here two cases of crusted scabies were treated with acitretin 30 mg daily and a 15% glycerine cream that achieved “complete remission after 6 weeks.”

Scleredema

Amy E. Flischel, Stephen E. Helms, and Robert T. Brodell

Scleredema (scleredema adultorum or scleredema of Buschke) is a connective tissue disorder characterized by progressive, symmetric induration and thickening of the skin secondary to increased amounts of collagen and glycosaminoglycans. Clinically, scleredema most commonly involves the posterior neck, shoulders, trunk, face, and

arms. Three clinical categories are recognized: type I, postinfectious, accounts for 55% of cases—this usually resolves spontaneously within 6 months to 2 years; type II, malignancy-associated, accounts for 25% of cases, including paraproteinemias and monoclonal gammopathy with or without multiple myeloma; and type III, scleredema diabeticorum, which is seen in 20% of cases and is associated with poorly controlled insulin-dependent diabetes and persists indefinitely.

Management Strategy

Treatment of scleredema is difficult and usually unsatisfactory. However, there are case-based data to support the effectiveness of several therapies. In many cases, a candid discussion with the patient regarding limitations of treatment, cost, and side effects will lead to a decision to withhold treatment. This is particularly appropriate in patients with the postinfectious form, which can resolve spontaneously without any specific therapy. Of course, identification of a specific etiology, such as streptococcal pharyngitis, should lead to appropriate antibiotic treatment, even in the absence of evidence that antibiotics would alter the rate of clearing in this self-limited form of scleredema. In the forms associated with diabetes mellitus and monoclonal gammopathy, progressive involvement can lead to discomfort, unsightly thickening, and even systemic complications such as restrictive pulmonary function, dysphagia secondary to tongue swelling, and cardiac arrhythmias. In these cases, patients will demand treatment.

Bath or cream PUVA has been recommended as initial therapy in moderately severe disease. More recently, narrowband UVB and UVA1 have been shown to be moderately effective. *Electron beam therapy* has been proposed as the leading recommendation for patients with severe disease, especially cases with restrictive pulmonary function. Alternative therapies have included *ciclosporin*, *allopurinol*, *tamoxifen*, and *high-dose penicillin*. Antidiabetic therapy has no effect on the evolution of scleredema in diabetics, as the progression of scleredema has been found to be unrelated to control of serum glucose levels.

Specific Investigations

- Fasting blood sugar, glucose tolerance test, hemoglobin A_{1c} (glycosylated hemoglobin)
- Serum protein electrophoresis, immunoelectrophoresis
- Antistreptolysin O, bacterial culture, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR)

Scleredema adultorum due to streptococcal infection

Alp H, Orbak Z, Aktas A. *Pediatr Int* 2003; 45: 101–3.

In 65% to 95% of cases, scleredema occurs within a few days to 6 weeks after an acute febrile illness. Of these infections, 58% are streptococcal. These infections may present as tonsillitis, pharyngitis, scarlet fever, erysipelas, cervical adenitis, pneumonia, otitis media, pyoderma, impetigo, or rheumatic fever. Appropriate studies will rapidly determine whether an underlying infection is associated with scleredema.

Monoclonal gammopathy in scleredema: observations in three cases

Kovary PM, Vakilzadeh F, Macher E, Zaun H, Merk H, Goerz G. *Arch Dermatol* 1981; 117: 536–9.

Many subsequent reports have confirmed this association. Skin manifestations often precede the development of the gammopathy.

Scleredema associated with carcinoma of the gall bladder

Manchanda Y, Das S, Sharma VK, Srivastava DN. *Br J Dermatol* 2005; 152: 1373–4.

Scleredema has been associated with various internal malignancies. When clinically indicated, an evaluation for internal malignancies may be appropriate.

First-Line Therapies

• Identify and treat underlying disease	D
• Conservative management	D

Scleredema: a review of 33 cases

Venencie PY, Powell FC, Su D, Perry HO. J Am Acad Dermatol 1984; 11: 128–34.

Systemic corticosteroids, methotrexate, and D-penicillamine demonstrated no effect on the disease course. Both diabetic and nondiabetic patients were studied, and although some patients in both groups suffered from mild complications such as dysphagia and electrocardiogram (ECG) changes, the authors emphasize that scleredema is generally a mild disease that poses no threat to overall health.

Scleredema adultorum. Not always a benign self-limited disease

Curtis AC, Shulak BM. Arch Dermatol 1965; 92: 526–41.

A review of 223 scleredema patients revealed that 25% have had symptoms for more than 2 years. The following treatments demonstrated no therapeutic benefit: calcium gluconate, estradiol, fever, hot baths, hyaluronidase, nicotinic acid, ovarian extract, p-aminobenzoate, penicillin, pituitary extract, corticosteroids, thyroid hormone, and vitamin D.

Fulminans in dermatology: a call to action: a recommendation for consideration of the term scleredema fulminans

Sommer LL, Heymann WR. J Clin Aesthet Dermatol 2014; 7: 42–5.

A 43-year-old man with an 11-year history of human immunodeficiency virus presented with a 3-month history of abrupt-onset progressive neck, shoulder, and back swelling shortly after the patient was diagnosed with type 2 diabetes. Though generally considered a chronic disease, this case demonstrates the rapidity of onset seen in some patients.

Second-Line Therapies

• Narrowband UVB phototherapy	E
• UVA1 phototherapy	D
• Electron beam therapy	E
• Bath PUVA and cream PUVA	E
• Physical therapy	E
• Tamoxifen	E
• High-dose penicillin	E
• Ciclosporin	E
• Extracorporeal photopheresis	E
• Chemotherapy (melphalan)	E
• Frequency-modulated electromagnetic neural stimulation	E
• Allopurinol	E
• Intravenous Immunoglobulin	E

Scleredema adultorum treated with narrow-band ultraviolet B phototherapy

Xiao T, Yang Z, He C, Chen H. J Dermatol 2007; 34: 270–2.

A 56-year-old Chinese man was treated with NB-UVB at an initial dose of 0.2 J/cm², three times weekly, increased by 25% per treatment. Significant improvement occurred after 10 treatments, and the patient received a total of 54 exposures (33.8 J/cm² dose). Beneficial effects were still evident 14 months after treatment was discontinued. NB-UVB phototherapy has several advantages over PUVA. It has shorter irradiation times, no need for protective glasses after treatment, and reduced risk of photocarcinogenesis. Further large-scale studies are needed to define the role of NB-UVB in scleredema.

UVA1 phototherapy for cutaneous diseases: an experience of 92 cases in the United States

Tuchinda C, Kerr H, Taylor C, Jacobe H, Bergamo B, Elmetts C, et al. Photodermatol Photoimmunol Photomed 2006; 22: 247–53.

Six patients with scleredema were treated with UVA1 phototherapy (five received low-dose regimens and one a medium-dose regimen).

One patient developed polymorphous light eruption and therapy was discontinued. Moderate-to-good responses were seen in four out of five patients treated. In recalcitrant cases UVA1 phototherapy should be considered as a therapeutic option.

Scleredema diabeticorum case series: successful treatment with UV-A1

Kroft EB, de Jong EM. Arch Dermatol 2008; 144: 947–8.

Three cases showed substantial clinical improvement after UVA1 therapy. Two patients were treated with 35 J/cm² per session and the third patient with 60 J/cm² per session.

Scleredema treated with broad-band ultraviolet A phototherapy plus colchicine

Yüksek J, Sezer E, Köseoğlu D, Markoç F, Yildiz H. Photodermatol Photoimmunol Photomed 2010; 26: 257–60.

A 23-year-old female with biopsy-confirmed scleredema was treated with low-dose broadband UVA phototherapy 15 J/cm², three times weekly for 40 sessions (total cumulative dose of 600 J/cm²) and colchicine 1800 mg/day for 1 year. Histopathologic and clinical improvement was noted. The authors conclude that more long-term follow-up studies in a larger series are needed.

Scleredema of Buschke successfully treated with electron beam therapy

Tamburin LM, Pena JR, Meredith R. Arch Dermatol 1998; 134: 419–22.

A patient with scleredema and insulin-dependent diabetes mellitus experienced complete resolution of skin induration after receiving electron beam therapy twice weekly for 36 days. Prior treatment with topical, intralesional, and systemic corticosteroids had failed. This patient also suffered significant restrictive pulmonary disease thought to be secondary to scleredema, and pulmonary function tests after electron beam therapy revealed marked improvement in lung function. This treatment should be considered in patients with severe persistent disease and systemic complications.

Electron-beam therapy in scleredema adultorum with associated monoclonal hypergammaglobulinaemia

Angeli-Besson C, Koeppel M, Jacquet P, Andrac L, Sayag J. Br J Dermatol 1994; 130: 394–7.

Ten sessions of electron beam therapy produced significant clinical improvement in the skin lesions of a patient with IgA κ monoclonal gammopathy. A trial of factor XIII and cyclofenil had proved unsuccessful. Although the patient had initially responded to systemic corticosteroids, she subsequently became resistant and the condition progressed. At that point, electron beam therapy was begun.

Paraproteinemia-associated scleredema treated successfully with intravenous immunoglobulin

Eastham AB, Femia AN, Velez NF, Smith HP, Vleugels RA. JAMA Dermatol 2014; 150: 788–9.

A woman in her forties with a 2-year history of progressive erythema and induration of the face, neck, and upper trunk denied recent infection or history of diabetes. There was significant limitation in range of motion of shoulders. After 2 cycles of IVIG given monthly, the patient noted significant improvement.

Bath-PUVA therapy in three patients with scleredema adutorum

Hager CM, Sobhi HA, Humzelmann N, Wickenhauser C, Scharenberg R, Krieg T, et al. J Am Acad Dermatol 1998; 38: 240–2.

Bath PUVA therapy (median of 59 treatments) produced substantial clinical improvement. One patient did not have a history of diabetes mellitus or preceding infection; the remaining two had diabetes. Diabetic patients with scleredema tend to have a long unremitting course without treatment.

Cream PUVA therapy for scleredema adutorum

Grundmann-Kollmann M, Ochsendorf F, Zollner TM, Spieth K, Kaufmann R, Podda M. Br J Dermatol 2000; 142: 1058–9.

Cream PUVA therapy (35 irradiations) produced marked clinical improvement and softening of the skin in a patient with a 10-year history of scleredema who also suffered non–insulin-dependent diabetes mellitus. Cream PUVA therapy is easier to administer than bath PUVA and may become an important treatment option for scleredema.

Ultrasonic massage and physical therapy for scleredema: improving activities of daily living

Bray SM, Varghese S, English JC 3rd. Arch Dermatol 2010; 146: 453–4.

A 42-year-old man with diabetes-associated scleredema was treated with hydroxychloroquine and psoralen UVA without clinical improvement. Physical therapy with ultrasonic massage, active range-of-motion exercises, and flexibility exercises three times a week was initiated. Ultrasonic massage therapy was performed using a Dynatron 709 series machine with the following parameters: 100%, 1 MHz, and 1.5 W/cm² for 10 minutes per session. The patient showed objective improvement in 9 of 10 range-of-motion parameters measured after 1 year of physical therapy.

Treatment of scleredema diabetorum with tamoxifen

Alsaedi SH, Lee P. *J Rheumatol* 2010; 37: 2636–7.

A 61-year-old woman with diabetic scleredema was treated with tamoxifen 20 mg twice daily after failing to improve after treatment with methotrexate and D-penicillamine. After 2 months, her symptoms improved, and after 48 months there was clinical evidence of softening of the skin on her back as well as improvement of shoulder flexibility. A 54-year-old female with diabetic scleredema was also treated with tamoxifen 20 mg twice daily and demonstrated similar improvement. Tamoxifen's antifibrotic effect may be an effective treatment for scleredema.

Persistent scleredema of Buschke in a diabetic: improvement with high-dose penicillin

Krasagakis K, Hettmannsperger U, Trautmann C, Tebbe B, Garbe C. *Br J Dermatol* 1996; 134: 597–8.

High-dose (3×10^6 IU daily) intravenous penicillin for 7 days led to a reduction in the severity of scleredema. Rather than acting as an antibiotic, penicillin appears to be effective because of its antifibrotic actions. This may explain why other antibiotics such as erythromycin are ineffective.

Cyclosporine in scleredema

Mattheou-Vakali G, Ioannides D, Thomas T, Lazaridou E, Tsogas P, Minas A. *J Am Acad Dermatol* 1996; 35: 990–1.

Ciclosporin at a dose of 5 mg/kg daily for 5 weeks was effective in completely clearing scleredema in two patients. Both presented with postinfectious scleredema and thus would have likely experienced resolution of their symptoms even without treatment.

Scleredema associated with paraproteinemia treated by extracorporeal photopheresis

Stables GI, Taylor PC, Highet AS. *Br J Dermatol* 2000; 142: 781–3.

Significant improvement in skin lesions followed treatment with extracorporeal photopheresis. When the treatment sessions were reduced from two per month to one, the patient's condition deteriorated, suggesting that the improvement was due to therapy rather than spontaneous resolution. Because scleredema associated with paraproteinemia usually has a progressive course, this treatment should be considered in patients with a similar presentation.

Beneficial effect of aggressive low-density lipoprotein apheresis in a familial hypercholesterolemic patient with severe diabetic scleredema

Koga N. *Ther Apher* 2001; 5: 506–12.

A 59-year-old woman with diabetic scleredema treated with weekly low-density lipoprotein (LDL) apheresis over a period of 3 years had significant improvement in her scleredema when her lipid levels were normalized. Histopathologic as well as clinical improvement was noted.

Treatment with chemotherapy of scleredema associated with IgA myeloma

Santos-Juanes J, Osuna CG, Iglesias JR, De Quiros JF, del Rio JS. *Int J Dermatol* 2001; 40: 720–1.

A 70-year-old woman with IgA myeloma and scleredema was treated with oral melphalan and prednisone over a 6-month period. During the 18 months she was followed, clinical evidence of softening of the indurated and taut skin was observed. Similar cases were cited in which chemotherapy for myeloma resulted in significant improvement of associated scleredema.

Treatment of acquired reactive perforating collagenosis with allopurinol incidentally improves scleredema diabeticorum

Lee FY, Chiu HY, Chiu HC. *J Am Acad Dermatol* 2011; 65: e115–7.

A 51-year-old man presented with acquired reactive perforating collagenosis associated with diabetes and scleredema of the upper back for over 20 years. Allopurinol 100 mg a day for 14 months proved effective for both conditions. Allopurinol is thought to improve endothelial function by profoundly reducing vascular

oxidative stress.

Successful treatment of poststreptococcal scleredema adutorum Buschke with intravenous immunoglobulins

Aichelburg MC, Loewe R, Schicher N, Sator PG, Karlhofer FM, Stingl G, et al. Arch Dermatol 2012; 148: 1126–8.

A 38-year-old woman with a 3-week history of rapidly progressing scleredema of the upper trunk 7 weeks after pharyngitis. After failure of initial treatment with penicillin, UVA-1 therapy, and methylprednisolone, IVIG was initiated at a dosage of 2 g/kg over 2 consecutive days every 4 weeks for five cycles. Initial improvement was noted 10 days after the first administration.

Improvement in clinical symptoms of scleredema diabeticorum by frequency-modulated electromagnetic neural stimulation: a case report

Gandolfi A, Pontara A, Di Terlizzi G, Rizzo N, Nicoletti R, Scavini M, et al. Diabetes Care 2014; 37: e233–4.

Scleredema associated with type 1 diabetes was treated with frequency-modulated electromagnetic neural stimulation (FREMS), transcutaneous electrotherapy, a safe and effective therapy commonly used for diabetic neuropathy. Ten to 15 sessions of FREMS were given at 3-month intervals over 15 months. Initial improvement in both mobility and the Barthel Index of activities of daily living was seen after two series. Despite the clinical improvement, no histologic changes could be identified.

Scleroderma

Mark J.D. Goodfield, and Ian H. Coulson

Systemic sclerosis (SSc), often called *scleroderma*, is a rare multisystem disease characterized by skin fibrosis, autoantibody production, and vascular abnormalities often leading to visceral disease. It can affect any organ system, particularly the gastrointestinal tract, kidney, heart, and lungs. Patients typically

present with cutaneous sclerosis or Raynaud phenomenon (RP). The degree of skin involvement defines the clinical subset of the disease. Diffuse cutaneous SSc (dcSSc) involves the skin proximal to the neck, elbows, or knees, whereas involvement distal to these sites is known as *limited cutaneous SSc* (lcSSc); some authors include an intermediate group. Localized scleroderma, or morphea, is a different condition.

Management Strategy

Limited cutaneous and dcSSc, with different severities and survivals, have been recognized as distinct subsets. Some authors have suggested an intermediate cutaneous form with intermediate survival.

In most cases cutaneous lesions and RP precede systemic involvement. The face and hands are typically involved, with patients displaying a characteristic shiny appearance of the skin and complaining of increased skin stiffness or rigidity. To date, no treatment has proved uniformly effective in modifying the course of the disease, and there is no specific therapy for the skin, although dry skin should be cared for daily using *emollient creams*. *Topical 0.025% to 0.05% tretinoin* may improve the perioral radial furrows and facial tightening. *Antihistamines* may help itch. Calcinosis cutis may require surgical removal of deposits, and *parenteral or intralesional sodium thiosulfate* is occasionally justified.

UVA phototherapy, Psoralens and Ultraviolet A, Ultraviolet A (PUVA and UVA1) has been reported to be effective in reducing skin thickness. *Vasodilators* such as *nifedipine* reduce vasospasm and improve peripheral blood flow. Also, *losartan*, an antagonist of angiotensin II receptor type I, has been found to be effective in reducing the severity and frequency of attacks of RP. Digital ulcers are a frequent problem in SSc—they may require antibiotics if they are infected, and recalcitrant ulcers may respond to a *PDE-5 antagonist* such as *sildenafil*. *Endothelin receptor antagonists* such as *bosentan* may improve digital perfusion. *Palmar sympathectomy* and *botulinum toxin injection* to digital nerves may be valuable. *Parenteral prostacyclin* analogs such as *iloprost* also improve both the severity and frequency of RP. Both *low-dose prednisolone* 20 mg/day and *methotrexate* 15 to 25 mg/week have been shown to reduce skin thickness scores. *ciclosporin* 3 to 4 mg/kg/day may improve skin induration, but has no effect on internal organ involvement. It should be used with caution as renal

involvement with SSc is not uncommon. *Mycophenolate* (0.5–1.5 g twice daily) is of value for both skin and lung involvement. *Cyclophosphamide* 1 to 2 mg/kg/day is of proven value in reducing skin scores and preventing the development of lung fibrosis and other complications, and *pulsed therapy with cyclophosphamide* is also effective and possibly safer.

Biologics, including *rituximab*, *infliximab*, *basiliximab*, and *imatinib*, have all been investigated with varying success. Trials of *stem cell transplantation* show promising efficacy in progressive dcSSc with a poor prognosis, but have significant side effects and a mortality of 5%; timing needs to be judged depending on significant renal, lung, or cardiac disease contraindications. Respiratory complications of SSc develop in roughly 30% of patients. Pulmonary hypertension (PAH) may occur and should be confirmed by appropriate investigation, including right heart catheterization. Iloprost infusions have also been shown to reduce PAH. *Angiotensin-converting enzyme (ACE) inhibitors* are particularly effective in reducing the renal complications of the disease, and early treatment may prevent the onset of renal crisis. *Proton pump inhibitors* treat esophageal disease effectively. Prokinetic dopamine agonists may help dysphagia and reflux. Intermittent broad-spectrum antibiotics (e.g., ciprofloxacin) may diminish bacterial overgrowth and blind loop syndrome. Recent randomized controlled trials have suggested that oral minocycline and D-penicillamine are not effective in SSc. Although SSc carries a high case-specific mortality, there have been significant advances in the management of skin, renal, and pulmonary complications. The identification of novel signaling pathways and mediators that are altered in SSc and contribute to tissue damage allows their selective targeting. This in turn opens the door for therapeutic strategies using novel compounds or innovative ways of using already approved drugs.

Rarely, older patients with late-onset disease and associated antipolymerase 3 antibodies may have scleroderma as a paraneoplastic phenomenon.

Specific Investigations

- Skin biopsy
- Renal function tests

- Blood pressure
- Anticentromere and anti-Scl-70 antibodies
- Chest x-ray
- Pulmonary function tests
- Echocardiography, natriuretic peptide
- Consider paraneoplastic disease and evaluation

Evidence-based guidelines for the use of immunologic tests: anticentromere, Scl-70, and nucleolar antibodies

Basu D, Reveille JD. Autoimmunity 2005; 38: 65–72.

Anti-Scl-70 antibodies are very useful in distinguishing SSc patients from healthy controls, from patients with other connective tissue diseases, and from unaffected family members. Among patients with SSc, anti-Scl-70 positivity is useful in predicting those at higher risk for diffuse cutaneous involvement and interstitial fibrosis/restrictive lung disease, though the latter has not been universally observed.

Once a patient is determined as being anti-Scl-70 positive or negative, there is little justification for serial determinations.

Cancer and scleroderma: a paraneoplastic disease with implications for malignancy screening

Shah AA, Casciola-Rosen L. Curr Opin Rheumatol 2015; 27: 563–70.

Emerging data have demonstrated that patients with scleroderma and RNA polymerase III autoantibodies have a significantly increased risk of cancer within a few years of scleroderma onset. Genetic alterations in the gene encoding RNA polymerase III (*POLR3A*) have been identified, and patients with somatic mutations in *POLR3A* have evidence of mutation-specific T-cell immune responses with generation of cross-reactive RNA polymerase III autoantibodies. These data strongly suggest that scleroderma is a by-product of antitumor immune responses in some patients. Additional epidemiologic data demonstrate that patients developing scleroderma at older ages may also have a short cancer–scleroderma interval, suggestive of paraneoplastic disease.

First-Line Therapies

• Nifedipine	A
• Iloprost	A
• ACE inhibitors	B
• Sildenafil	C

Iloprost for the treatment of systemic sclerosis

Hachulla E, Launay D, Hatron P-Y. Presse Med 2008; 37: 831–9.

An imbalance between prostacyclin (PGI₂) and thromboxane A₂ is observed in patients with scleroderma. Iloprost is a stable analog of PGI₂ with a plasma half-life of 20 to 30 minutes. Intravenous iloprost is effective in the treatment of RP related to scleroderma, reducing the frequency and severity of attacks. It also appears useful for the treatment of digital ulcers. Intravenous iloprost improves kidney vasospasm in patients with scleroderma. The possible benefits of sequential intravenous iloprost on the natural course of scleroderma require further investigation.

Calcium channel blockers for Raynaud's phenomenon

Thompson AE, Pope JE. Rheumatology 2005; 44: 145–50.

Calcium channel blockers yield moderate clinical improvement in the severity and frequency of Raynaud attacks, with an average decrease of 2.8 to 5.0 attacks per week and a 33% improvement in the severity of attacks compared with placebo.

Outcome of renal crisis in systemic sclerosis: relation to availability of angiotensin converting enzyme (ACE) inhibitors

Steen VD, Costantino JP, Shapiro AP, Medsger TA Jr. Ann Intern Med 1990; 113: 352–7.

Patients with SSc who develop hypertension should be treated with an ACE inhibitor. Improved survival and successful discontinuation of dialysis are possible when ACE inhibitors are used to treat scleroderma-related renal crisis.

Prospective, open-label, uncontrolled pilot study to study safety and efficacy of sildenafil in systemic sclerosis-related pulmonary artery hypertension and cutaneous vascular complications

Kumar U, Sankalp G, Sreenivas V, Kaur S, Misra D. *Rheumatol Int* 2013; 33: 1047–52.

A prospective, open-label, uncontrolled pilot study to examine the safety and efficacy of oral sildenafil in PAH, RP, digital infarcts, and ulcers in SSc. Seventeen patients fulfilling American College of Rheumatology (ACR) classification criteria for scleroderma and who had PAH were recruited. All patients were treated with oral sildenafil 25 mg three times a day for a period of 3 months. The pretreatment and posttreatment values of mean pulmonary artery pressure (mPAP), 6-min walk test, World Health Organization (WHO) class of dyspnea, and severity of RP were compared to look for any significant change. Sixteen patients who completed the 3-month follow-up had shown statistically significant improvement in 6-min walk test, WHO class of dyspnea, severity of RP, and mPAP. Also, there was no occurrence of new digital infarcts or ulcers, and existing ulcers showed signs of healing. Sildenafil is highly efficacious, cheaper, and a safe alternative to other available therapies for SSc-associated PAH, RP, and digital infarcts/ulcers.

Second-Line Therapies

• Methotrexate	A
• Cyclophosphamide	B
• Prednisolone	B
• Losartan	B
• Acitretin	C
• Colchicine	C
• UVA	C
• Mycophenolate	C

Treatment outcome in early diffuse cutaneous systemic sclerosis: the European Scleroderma Observational Study (ESOS)

Herrick AL, Pan X, Peytrignet S, Lunt M, Hesselstrand R, Mouthon L, et al. Ann Rheum Dis 2017; 76: 1207–18.

A prospective, observational cohort study of early dcSSc (within 3 years of onset of skin thickening) over 2 years. Clinicians selected one of four protocols for each patient: methotrexate, mycophenolate mofetil (MMF), cyclophosphamide, or “no immunosuppressant.” The primary outcome was the change in modified Rodnan skin score (mRSS). As a secondary outcome, an Inverse Probability of Treatment (IPT)-weighted Cox model was used to test for differences in survival.

Of 326 patients, 65 were prescribed methotrexate, 118 MMF, 87 cyclophosphamide, and 56 no immunosuppressant. A reported 276 (84.7%) patients completed 12 months and 234 (71.7%) 24 months' follow-up (or reached the last visit date). There were statistically significant reductions in mRSS at 12 months in all groups: -4.0 (-5.2 to -2.7) units for methotrexate, -4.1 (-5.3 to -2.9) for MMF, -3.3 (-4.9 to -1.7) for cyclophosphamide, and -2.2 (-4.0 to -0.3) for no immunosuppressant (p value for between-group differences = 0.346).

There were no statistically significant differences in survival between protocols before ($p = 0.389$) or after weighting ($p = 0.440$), but survival was poorest in the no immunosuppressant group (84.0%) at 24 months.

Randomized placebo controlled trial of methotrexate in systemic sclerosis

Das SN, Alam MR, Islam N, Rahman MH, Sutradhar SR, Rahman S, et al. Mymensingh Med J 2005; 14: 71–4.

Clinical improvement after treatment was observed in a third of patients in the methotrexate (MTX) group but none in the placebo group, but this difference was not statistically significant. Anorexia, nausea, and occasional vomiting were common side effects in the MTX group and subsided in most cases with the passage of time, despite the continuation of therapy.

The efficacy of oral cyclophosphamide plus prednisolone in early diffuse systemic sclerosis

Calguneri M, Apras S, Ozbalkan Z, Ertenli I, Kiraz S, Ozturk MA, et al. Clin Rheumatol 2003; 22: 289–94.

In this study 27 patients with early diffuse SSc were treated with oral cyclophosphamide (1–2 mg/kg/day) plus oral prednisolone (40 mg every other day) between the years 1995 and 1998. The results regarding the efficacy and toxicity of cyclophosphamide were compared with those of 22 early SSc patients who had been treated with oral D-penicillamine between 1992 and 1995. There was a significant improvement in the skin score, maximal oral opening, flexion index, predicted forced vital capacity, and carbon monoxide diffusing capacity in the cyclophosphamide group. The decrease in skin score in the cyclophosphamide group started earlier than in the D-penicillamine group.

Randomized unblinded trial of cyclophosphamide versus azathioprine in the treatment of systemic sclerosis

Nadashkevich O, Davis P, Fritzler M, Kovalenko W. Clin Rheumatol 2006; 25: 205–12.

Thirty patients were assigned to receive oral cyclophosphamide (2 mg/kg daily for 12 months and then maintained on 1 mg/kg daily), and 30 patients were assigned to receive oral azathioprine (2.5 mg/kg daily for 12 months and then maintained on 2 mg/kg daily). During the first 6 months of the trial the patients also received prednisolone, which was started at a dosage of 15 mg daily and tapered to zero by the end of the sixth month. This study showed that cyclophosphamide is a promising disease-modifying medication for SSc, as it exhibited a positive influence on the evolution of disease.

Efficacy and safety of intravenous cyclophosphamide pulse therapy with oral prednisolone in the treatment of interstitial lung disease with systemic sclerosis: 4-year follow-up

Tochimoto A, Kawaguchi Y, Hara M, Tateishi M, Fukasawa C, Takagi K, et al. Mod Rheumatol 2011; 21: 296–301.

This open-label study of pulsed cyclophosphamide ($0.49/\text{m}^2$) with oral prednisolone concluded that the regimen was effective in producing improvement in interstitial lung disease (and skin disease), but that relapse was common, occurring in 5 of 13 patients, so maintenance therapy should be investigated.

Treatment of early diffuse cutaneous systemic sclerosis patients in Japan by low-dose corticosteroids for skin involvement

Takehara K. Clin Exp Rheumatol 2004; 22: S87–9.

Twenty-three patients with early dcSSc were treated with 20 mg/kg of prednisolone, with a significant reduction in skin scores.

Retinoic acid for treatment of systemic sclerosis and morphea: a literature review

Thomas RM, Worswick S, Aleshin M. Dermatol Ther 2017; 30: e12455.

A review of the current status of utilizing retinoids for scleroderma and morphea.

Losartan therapy for Raynaud's phenomenon and scleroderma: clinical and biochemical findings in a fifteen-week, randomized, parallel-group, controlled trial

Dziadzio M, Denton CP, Smith R, Blann HK, Bowers E, Black CM. *Arthritis Rheum* 1999; 42: 2646–55.

Losartan is an antagonist of angiotensin II receptor type I. In this randomized controlled trial 25 patients with primary RP and 27 with RP secondary to SSc were treated with either losartan (50 mg/day) or nifedipine (40 mg/day). Losartan reduced the frequency and severity of RP.

Therapeutic management of acral manifestations of systemic sclerosis

Meyer MF, Daigeler A, Lehnhardt M, Steinau H-U, Klein HH. *Med Klin* 2007; 102: 209–18.

Patients with acral manifestations of SSc are ideally treated by a team that includes a rheumatologist, dermatologist, hand surgeon, physiotherapist, and, eventually, a psychologist. Calcium channel antagonists, α_1 -adrenergic blockade with prazosin, and prostacyclin analogs proved to be effective in the treatment of scleroderma-related RP. Losartan, an angiotensin II receptor inhibitor, and fluoxetine, a selective serotonin reuptake inhibitor, have been beneficial for SSc-associated RP in pilot studies.

Long-term evaluation of colchicine in the treatment of scleroderma

Alarcon-Segovia D, Ramos-Niembro F, Ibanez de Kasep G, Alcocer J, Perez-Tamayo R. *J Rheumatol* 1979; 6: 705–12.

In this early uncontrolled study, 19 patients with dcSSc were treated with colchicine 10.1 mg/week with a follow-up of 19 to 57 months. They reported improvement in skin elasticity, mouth opening, and finger mobility and a reduction in dysphagia.

Different low doses of broad-band UVA in the treatment of morphea and systemic sclerosis

El-Mofty M, Mostafa W, El-Darouty M, Bosseila M, Nada H, Yousef R, et al. *Photodermatol Photoimmunol Photomed* 2004; 20: 148–56.

Fifteen patients complaining of SSc received 20 sessions of UVA (320–400 nm); all improved clinically.

UVA is well tolerated, and there is experimental evidence that UVA1 may be beneficial. Further trials are required to confirm efficacy.

Effect of mycophenolate sodium in scleroderma-related interstitial lung disease

Simeón-Aznar CP, Fonollosa-Plá V, Tolosa-Vilella C, Selva-O'Callaghan A, Solans-Laqué R, Vilardell-Tarrés M. Clin Rheumatol 2011; 30: 1393–8.

An open-label study in 14 patients (dose 0.5–1.5 g twice a day) showed stabilization of pulmonary diffusion capacity.

A prospective open-label study of mycophenolate mofetil for the treatment of diffuse systemic sclerosis

Derk CT, Grace E, Shenin M, Naik M, Schulz S, Xiong W. Rheumatology (Oxford) 2009; 48: 1595–9.

Fifteen patients with dcSSc took part in an open-label study using MMF to treat their disease over a 12-month period. The mRSS significantly improved in those patients who tolerated the medication for longer than 3 months, as did severity scores of the general, peripheral vascular involvement, and skin. Pulmonary function studies showed a trend toward improvement, though not of statistical significance. The mPAP by two-dimensional echocardiography did not change.

Third-Line Therapies

• Extracorporeal photochemotherapy	B
• Imatinib	B
• Ciclosporin	C
• Rituximab	C
• Autologous nonmyeloablative hemopoietic stem cell transplantation	C
• Etanercept	D

Systemic Sclerosis Study Group. A randomized, double-blind, placebo-controlled trial of photopheresis in systemic sclerosis

Knobler RM, French LE, Kim Y, Bisaccia E, Graninger W, Nahavandi H, et al. J Am Acad Dermatol 2006; 54: 793–9.

This randomized, double-blind, placebo-controlled clinical trial was conducted at 16 investigational sites in the United States, Canada, and

Europe. Sixty-four patients with typical clinical and histologic findings of scleroderma of less than 2 years' duration were studied to evaluate the efficacy of photopheresis in the treatment of patients with SSc. Photopheresis induced significant improvement of skin and joint involvement in patients with scleroderma of recent onset.

Imatinib mesylate (Gleevec) in the treatment of diffuse cutaneous systemic sclerosis: results of a 1-year, phase IIa, single-arm, open-label clinical trial

Spiera RF, Gordon JK, Mersten JN, Magro CM, Mehta M, Wildman H, et al. *Ann Rheum Dis* 2011; 70: 1003–9.

Twenty-four of 30 patients showed an improved modified Rodnan skin score of more than 20% after 12 months of 400 mg daily of imatinib. Pulmonary diffusing capacity was stabilized. Unfortunately, adverse events were common and often severe.

Ciclosporin in systemic sclerosis

Clements PJ, Lachenbruch PA, Sterz M, Danovitch G, Hawkins R, Ippoliti A, et al. *Arthritis Rheum* 1993; 36: 75–83.

ciclosporin is an immunosuppressive drug that selectively inhibits the release of interleukin-2 (IL-2), which has been shown to be increased in SSc serum. This study showed that ciclosporin may improve skin induration, but had no effect on internal organ involvement.

The high incidence of nephrotoxicity with ciclosporin therapy reduces its use in SSc where renal crisis may occur.

B cell depletion in diffuse progressive systemic sclerosis: safety, skin score modification and IL-6 modulation in an up to thirty-six months follow-up open-label trial

Bosello S, De Santis M, Lama G, Spanò C, Angelucci C, Tulusso B, et al. *Arthritis Res Ther* 2010; 12: R54.

Rituximab (1 g by infusion twice at an interval of 2 weeks) improved the modified Rodnan skin score by a median of 43.3% in nine patients with diffuse type SSc. Treatment was well tolerated and appeared safe after 36 months follow-up. Retreatment was necessary in two patients to treat joint disease.

Autologous hematopoietic stem cell transplantation has better outcomes than conventional therapies in patients with rapidly

progressive systemic sclerosis

Del Papa N, Onida F, Zaccara E, Saporiti G, Maglione W, Tagliaferri E, et al. Bone Marrow Transplant 2017; 52: 53–8.

A retrospective evaluation of the efficacy of autologous hematopoietic stem cell transplantation (AHSCT) in 18 patients with rapidly progressive diffuse cutaneous systemic sclerosis (rp-dcSSc), comparing their disease outcomes with those of 36 demographically and clinically matched patients treated with conventional therapies. Cutaneous involvement, measured by a modified Rodnan skin score (mRss), lung diffusion capacity measured by diffusing capacity of lung for carbon monoxide (DLCO), and disease activity utilizing the European Scleroderma Study Group (ESSG) scoring system, were the outcome variables measured at the baseline time and then every 12 months for the following 60 months in both the AHSCT-treated patients and the control group. In the AHSCT group, treatment-related mortality was 5.6%. In this group, both mRss and ESSG scores showed a significant reduction 1 year after AHSCT ($p < 0.002$); these results were maintained until the end of follow-up. Conversely, DLCO values remained stable during the whole period of follow-up. Survival rate of the AHSCT group was much higher than that observed in the whole control group ($p = 0.0005$).

This study confirms that the AHSCT is effective in prolonging survival, as well as in inducing a rapid reduction of skin involvement and disease activity, and preserving lung function in patients with rp-dcSSc.

Etanercept as treatment for diffuse scleroderma: a pilot study

Ellman MH, McDonald PA, Hayes FA. Arthritis Rheum 2000; 43: s392.

This targeted fusion protein blocks TNF- α . Four out of 10 patients treated with etanercept 25 mg subcutaneously twice weekly had improvements of skin scores and healing of digital ulcers.

Other: Internal Organ Involvement

Prostacyclin for pulmonary hypertension in adults

Paramothayan NS, Lasserson TJ, Wells AU, Walters EH. Cochrane Database Syst Rev 2005; 2: CD002994.

There is evidence that intravenous prostacyclin, in addition to

conventional therapy at tolerable doses optimized by titration, can confer some short-term benefits (up to 12 weeks of treatment) in exercise capacity, New York Heart Association (NYHA) functional class, and cardiopulmonary hemodynamics. There is also some evidence that patients with more severe disease based on NYHA functional class showed a greater response to treatment.

Review of bosentan in the management of pulmonary arterial hypertension

Gabbay E, Fraser J, McNeil K. Vasc Health Risk Manage 2007; 3: 887–900.

Bosentan was the first endothelin receptor antagonist approved for use in PAH. Clinical studies have shown that in PAH the use of bosentan is associated with improved exercise capacity, WHO functional class, cardiopulmonary hemodynamics, and quality of life and delayed time to clinical worsening compared with placebo. Further, long-term studies have demonstrated improved survival with the use of bosentan compared with historical controls, although there are no placebo-controlled data confirming a survival benefit.

Bosentan therapy for pulmonary arterial hypertension

Rubin LJ, Badesch DB, Barst RJ, Galie N, Black CM, Keogh A, et al. N Engl J Med 2002; 346: 896–903.

In this randomized control trial of patients with PAH, the dual endothelin receptor antagonist bosentan improved exercise capacity. SSc patients with PAH were shown to have improved exercise capacity on subgroup analysis.

Interstitial lung disease associated with systemic sclerosis: what is the evidence for efficacy of cyclophosphamide?

Berezne A, Valeyre D, Ranque B, Guillevin L, Mouthon L. Ann NY Acad Sci 2007; 1110: 271–84.

Since 1993, the beneficial effect of oral or intravenous cyclophosphamide in the treatment of SSc-related ILD has been reported in retrospective studies, with one showing improvement of pulmonary function test scores and/or chest CT at 1 year and improvement of survival at 16 months. The results of two controlled trials were recently reported. The Scleroderma Lung Study, a prospective, randomized, placebo-controlled trial, included 158 patients, of which 145 completed at least 6 months of treatment. The

course of forced vital capacity (primary outcome) adjusted at 1 year was significantly better in the group treated with oral cyclophosphamide ($p < 0.03$), although the effect of cyclophosphamide was minor.

Cyclophosphamide is associated with pulmonary function and survival benefit in patients with scleroderma and alveolitis

White B, Moore WC, Wigley FM, Xiai HQ, Wise RA. *Ann Intern Med* 2000; 132: 947–54.

This retrospective cohort study involving 103 patients with SSc showed that lung inflammation (alveolitis) treated with cyclophosphamide improves lung function outcome and survival.

Renal transplantation in scleroderma

Chang YJ, Spiera H. *Medicine* 1999; 78: 382–5.

A retrospective study from data collected by the United Network for Organ Sharing (UNOS) Scientific Renal Transplant Registry. Between 1987 and 1997, 86 patients with SSc had renal transplantation. At 5-year follow-up, 47% of the patients were still alive. Patients whose renal function does not improve with ACE inhibitors should be considered for transplantation.

Sebaceous hyperplasia

Surod Qazaz, and John Berth-Jones

Sebaceous hyperplasia is a common benign condition mainly affecting adults of middle age and older, but it may occur at any time or even be present at birth. Lesions can be single or multiple and manifest as soft yellow papules, often with central umbilication, typically measuring 1 to 4 mm, mainly on the face (commonly the nose, cheeks, and forehead). Sebaceous hyperplasia occasionally appears in other areas such as the chest, areola, mouth, and genitalia.

There are occasional reports of giant lesions or arrangement in linear or zosteriform patterns. They appear more frequently in immunocompromised patients, especially after transplantation in patients on ciclosporin and corticosteroids.

Management Strategy

Sebaceous hyperplasia is a completely benign condition that does not require treatment; however, lesions can be cosmetically unfavorable. There may also be concern over differential diagnoses, which include basal cell carcinoma, rhinophyma, angiofibroma, trichoepithelioma, nevus sebaceous, dermal nevus, plane warts, lupus miliaris disseminatus faciei, and syringoma.

We normally use *cautery (electrodesiccation)* or *cryotherapy* first line. It can be helpful to treat one or two test lesions to assess patient satisfaction before treating the rest. Cryotherapy can be fairly gentle in view of the benign nature of the lesions, and it can be helpful to protect surrounding skin using an auriscope speculum. Other treatments include *surgical excision*, *photodynamic therapy*, *laser*, *isotretinoin*, and *chemical peels*. Because the objective is cosmetic improvement, it is important to inform the patient about the risk of scarring with these techniques. Occasionally, sebaceous hyperplasia is treated surgically. This has the advantage of providing tissue for histology when there is any doubt about the diagnosis. Shave excision or curettage is usually sufficient, both to obtain histologic confirmation and to achieve removal with minimal scarring.

Specific Investigation

- No specific investigations are usually required, as the diagnosis is clinical.

Biopsy is occasionally indicated, mainly to exclude basal cell carcinoma; histology will show enlargement of individual glands with increased numbers of fully mature sebaceous lobules with no atypia or dysplasia.

Alta prevalencia de hiperplasias sebaceas en transplantados renales

Perez-Espana L, Prats I, Sanz A, Mayor M. Nefrologia 2003; 23: 179–80.

The authors looked at 163 renal transplant patients, of whom 26% had sebaceous hyperplasia. This was greatest in patients on ciclosporin. Other immunosuppressants (azathioprine, mycophenolate mofetil, and tacrolimus) showed no significant increase in the incidence of sebaceous hyperplasia.

First-Line Therapies

• Conservative management/cosmetic camouflage	E
• Electrodesiccation/cautery	C
• Cryotherapy	E

Surgical pearl: intralesional electrodesiccation of sebaceous hyperplasia

Bader RS, Scarborough DA. J Am Acad Dermatol 2000; 42: 127–8.

The authors describe a nice technique for intralesional electrodesiccation using a fine epilating needle. They report no recurrence in more than 30 lesions followed up to 7 months.

Guidelines of care for cryosurgery

American Academy of Dermatology Committee on Guidelines of Care. J Am Acad Dermatol 1994; 31: 648–53.

The authors include sebaceous hyperplasia as a condition treatable with cryotherapy.

Second-Line Therapies

• Surgery/curettage	E
• Isotretinoin	B
• Photodynamic therapy	C
• Topical retinoids	E

Successful treatment of ciclosporin-induced sebaceous hyperplasia with oral isotretinoin in two renal transplant recipients

McDonald SK, Goh MS, Chong AH. *Australas J Dermatol* 2011; 52: 227–30.

Treatment was effective and well tolerated.

Presenile diffuse familial sebaceous hyperplasia successfully treated with low-dose isotretinoin: a report of two cases and review of the published work

Liu YS, Cheng YP, Liu CI, Yang CY, Yang CY. *J Dermatol* 2016; 43: 1205–8.

Two cases of presenile diffuse familial sebaceous hyperplasia were successfully treated without recurrence with prolonged low-dose isotretinoin (0.2 mg/kg per day, a cumulative dose of 41 and 64 mg/kg, respectively).

Sebaceous hyperplasia: systemic treatment with isotretinoin

Tagliolatto S, Santos Neto Ode O, Alchorne MM, Enokihara MY. *An Bras Dermatol* 2015; 90: 211–5.

Twenty patients were treated with isotretinoin in a prospective study. Each received 1 mg/kg per day for 2 months. The number of the lesions decreased significantly, with benefit persisting after 2 years.

Treatment of sebaceous gland hyperplasia by photodynamic

therapy with 5-aminolevulinic acid and a blue light source or intense pulsed light source

Gold MH, Bradshaw VL, Boring MM, Bridges TM, Biron JA, Lewis TL. J Drugs Dermatol 2004; 3: S6–9.

Twelve patients were randomized to topical aminolevulinic acid and either blue light or intense pulsed light. They had four treatments at 1-month intervals. Both treatment arms had more than 50% reduction in the number of the lesions without recurrence at 12 weeks' follow-up.

Third-Line Therapies

• Topical aminolevulinic acid and pulsed dye laser	D
• Pulsed dye laser	D
• Diode laser	D
• Argon laser	E
• Carbon dioxide laser	E
• Erbium:YAG laser	E
• 1720-nm laser	E
• Bichloroacetic acid	C
• Pin hole with squeezing technique	E

Photodynamic therapy with topical aminolevulinic acid and pulsed dye laser irradiation for sebaceous hyperplasia

Alster TS, Tanzi EL. J Drugs Dermatol 2003; 2: 501–4.

Ten patients were treated with topical 5-ALA followed 1 hour later by the 595-nm pulsed dye laser. They were compared with untreated lesions and laser-only-treated lesions. Laser photodynamic therapy yielded the best results; 70% of lesions had total clearing after one treatment, the remaining 30% after two treatments.

Elucidating the pulsed-dye laser treatment of sebaceous

hyperplasia in vivo with real-time confocal scanning laser microscopy

Aghassi D, Gonzalez E, Anderson RR, Rajadhyaksha M, Gonzalez S. J Am Acad Dermatol 2000; 43: 49–53.

The authors treated 29 lesions on seven different patients with pulsed dye laser. There was improvement in 93% of lesions and complete clearance in 28%. No scarring or hyperpigmentation was noted. However, 28% of the lesions reappeared and 7% returned to their original size.

Pulsed-dye laser for treatment of sebaceous hyperplasia

Tsai T-H, Chang Y-J. J Am Acad Dermatol 2012; 664 (Suppl 1): AB215.

In this randomized, controlled, split-face trial, Asian (skin types 3–5) patients received two treatments separated by a 4-week interval, with one half of the face treated with long-pulsed dye laser (5 mm, 595-nm pulsed dye laser at pulse duration of 10 ms), and the other half of the face with short-pulsed dye laser (5-mm pulses of the 595-nm pulsed dye laser at pulse duration of 0.45 ms). Fluences ranged from 7 to 10 J/cm². The short pulse achieved more obvious improvement of sebaceous hyperplasia than the long-pulsed dye laser, but adverse effects after short pulse included obvious purpura, which lasted about 1 to 2 weeks, and a few cases of crusts and postinflammatory hyperpigmentation. After long-pulsed dye laser, mild erythema and swelling lasted a few days without purpura.

Sebaceous hyperplasia treated with a 1450-nm diode laser

No D, McLaren M, Chotzen V, Kilmer SL. Dermatol Surg 2004; 30: 382–4.

The authors treated 10 patients. Both objective and subjective improvement was noted in the majority of patients, with very few side effects.

A 3 year experience with the argon laser in dermatotherapy

Landthaler M, Haina D, Waidelich W, Braun-Falco O. J Dermatol Surg Oncol 1984; 10: 456–61.

The authors report on 477 patients with different cutaneous lesions treated with an argon laser, including sebaceous hyperplasia.

Sebaceous gland hyperplasia as a side effect of cyclosporin A. Treatment with the CO₂ laser

Walther T, Hohenleutner U, Landthaler M. Dtsch Med Wochenschr 1998; 123: 798–800.

This article reports the treatment of a patient with CO₂ laser. The lesions cleared without scarring.

Controlled cosmetic dermal ablation in the facial region with the erbium:YAG laser

Riedel F, Bergler W, Baker-Schreyer A, Stein E, Hormann K. HNO 1999; 47: 101–6.

This article reports on 216 patients with different facial lesions. The authors report good to excellent results with sebaceous hyperplasia.

Treatment of sebaceous hyperplasia with a novel 1720-nm laser

Winstanley D, Blalock T, Houghton N, Ross EV. J Drugs Dermatol 2012; 11: 1323–6.

Four patients were treated with a test treatment followed by two full treatment sessions. At 3 months post treatment, there was nearly complete clearance without residual scarring.

The treatment of benign sebaceous hyperplasia with the topical application of bichloroacetic acid

Rosian R, Goslen JB, Brodell RT. J Dermatol Surg Oncol 1991; 17: 876–9.

The authors treated 67 lesions in 20 patients: 66 cleared after one application of 100% bichloroacetic acid, with minimal scarring.

Sebaceous hyperplasia effectively improved by the pin-hole technique with squeezing

Jae-Hong K, Hwa-Young P, Won-Soo L, Jin-Soo K. Ann Dermatol 2013; 25: 257–8.

The authors describe a technique of creating a 1-mm pinhole into the lesion with a carbon dioxide laser followed by squeezing the lesion with a comedo extractor. The procedure was performed with topical anesthetic cream. Most of the lesions were flattened after the treatment. There was no recurrence of any of the lesions 3 months after the treatment.

Seborrheic eczema

Anja K. Weidmann, Jason D.L. Williams, and Ian Coulson

Seborrheic eczema (seborrheic dermatitis) is a chronic dermatitis affecting between 3% and 10% of adults, becoming more prevalent with age. It is more common in patients with both idiopathic and neuroleptic-induced Parkinson disease, HIV, AIDS, and chronic alcoholics and accounts for up to 3.5% of dermatology specialist outpatient consultations.

The signs and symptoms comprise erythema, greasy scaling,

pruritus, burning, and dryness in a typical distribution pattern affecting the scalp and the face (particularly the nasolabial folds, eyebrows, and ears). Blepharoconjunctivitis may occur alone or in conjunction with skin lesions.

Seborrheic eczema can also affect infants up to the age of 3 to 4 months in the diaper area.

Although the etiology has yet to be fully elucidated, important factors are *Malassezia* yeasts, immune status, and individual susceptibility.

Management Strategy

Seborrheic eczema is a chronic relapsing dermatitis that responds to a variety of immunosuppressive and antifungal therapies, but there is no cure.

Seborrheic eczema of the face is dry and flaky, so that soap avoidance and substitution with a *light emollient cleanser* will help. Facial and flexural disease responds to *mild topical corticosteroids*, alone or in combination with a variety of *topical antipityrosporal agents* such as *miconazole*, *ketoconazole*, *bifonazole*, *itraconazole*, or *ciclopir oxolamine*. An ointment containing *lithium gluconate/succinate* may also be helpful.

Studies have demonstrated short-term efficacy with the topical calcineurin inhibitors *tacrolimus* and *pimecrolimus*. *Terbinafine cream* and *metronidazole gel* may also be beneficial, whereas resistant cases may respond to short courses of *oral itraconazole* or *terbinafine*.

Scalp seborrheic dermatitis can be helped with *topical ketoconazole*, *zinc pyrithione*, *selenium sulfide*, *corticosteroid* and *tar* shampoos, or a *propylene glycol* preparation formulated for scalp use. Severe cases with marked hyperkeratosis or pityriasis amiantacea may require topical keratolytics such as *salicylic acid ointment* or *coconut compound ointment*.

Specific Investigations

- Dermoscopy
- Tests for HIV infection
- Zinc levels

In neonates and children consider acrodermatitis enteropathica or transient neonatal zinc deficiency, which can mimic recalcitrant seborrheic dermatitis. A similar eruption in parenterally fed adults also can occur due to zinc deficiency.

Seborrheic dermatitis may represent a marker for HIV infection and should prompt consideration of testing.

Dermoscopy can be useful in differentiating scalp psoriasis from seborrhoeic dermatitis

Kim GW, Jung HJ, Ko HC, Kim MB, Lee WJ, Lee SJ, et al. Br J Dermatol 2011; 164: 652–6.

Dermoscopy features on the scalp include arborizing vessels and comma vessels.

These findings appear to have been replicated in several later studies. It may be of value to readers as a means of differentiating from scalp psoriasis.

New insights into HIV-1-primary skin disorders

Cedeno-Laurent F, Gómez-Flores M, Mendez N, Ancer-Rodríguez J, Bryant JL, Gaspari AA, et al. Int AIDS Soc 2011; 24: 14–5.

This article reports seborrheic dermatitis in up to 40% of patients with HIV with worsening severity as lymphocyte counts decline. Incidence in patients with AIDS is up to 80%.

Seborrheic dermatitis in neuroleptic-induced parkinsonism

Binder RL, Jonelis FJ. Arch Dermatol 1983; 119: 473–5.

Comparison of 42 hospitalized patients with drug-induced parkinsonism using psychiatric patients as controls showed an incidence of seborrheic dermatitis of 59.5% in those with parkinsonism, compared with 15% in the control group.

Cutaneous changes in chronic alcoholics

Rao GS. Indian J Dermatol Venereol Leprol 2004; 70: 79–81.

In this study of 200 alcoholic patients attending for alcohol detoxification, seborrheic dermatitis was the second most common skin disorder (11.5% of cases).

Nonscalp Disease

First-Line Therapies

• Topical ketoconazole	A
• Mild to moderate topical corticosteroids	A
• Emollients and soap substitutes	D

Ketoconazole 2% cream versus hydrocortisone 1% cream in the treatment of seborrhoeic dermatitis. A double-blind comparative study

Stratigos JD, Antoniou C, Katsambas A, Böhler K, Fritsch P, Schmölz A, et al. J Am Acad Dermatol 1988; 19: 850–3.

In this double-blind study, 72 patients were treated daily for 4 weeks with either ketoconazole 2% cream or hydrocortisone 1% cream; 80.5% of the ketoconazole group showed a significant improvement in all symptoms compared with 94.4% of the hydrocortisone group. There was no significant difference in relapse rates between the two groups.

Topical antifungals for seborrhoeic dermatitis

Okokon EO, Verbeek JH, Ruotsalainen JH, Ojo OO, Bakhoya VN. Cochrane Database Syst Rev 2015; 5: CD008138.

This review included 51 studies with a total of 9052 participants examining a wide range of treatments. Eight trials compared use of topical 2% ketoconazole with placebo or vehicle. Active treatment was associated with a 31% lower risk of failure of clearance. Six trials compared topical ketoconazole with topical steroids. Remission rates were similar (RR 1.17, 95% confidence interval [CI] 0.58–1.64), but occurrence of side effects was 44% lower in the ketoconazole group. Quality of data was limited by study duration and heterogeneity between studies.

Second-Line Therapies

• Lithium succinate/lithium gluconate	A
• Ciclopirox olamine cream	A
• Topical calcineurin inhibitors	A
• Topical azoles (miconazole/clotrimazole)	A

Lithium gluconate 8% vs. ketoconazole 2% in the treatment of seborrheic dermatitis: a multicenter, randomized study

Dreno B, Chosidow O, Revuz J, Moyse D. Br J Dermatol 2003; 148: 1230–6.

This randomized, noninferiority study compared 8% lithium gluconate twice daily for 8 weeks with ketoconazole 2% twice weekly for 4 weeks then once weekly for a further 4 weeks in moderate-to-severe seborrheic dermatitis. Two hundred and sixty-nine patients were treated, and complete response was achieved in 52.0% and 30.1%, respectively.

Randomized, placebo-controlled, double-blind study on clinical efficacy of ciclopirox olamine 1% cream in facial seborrheic dermatitis

Dupuy P, Maurette C, Amoric JC, Chosidow O. Br J Dermatol 2001; 144: 1033–7.

One hundred and twenty-nine patients were randomized to receive either 1% ciclopirox olamine cream twice daily for 28 days, followed by once-daily application for a further 28 days, or placebo. At 8 weeks, 63% of patients in the ciclopirox olamine group achieved clearance of their test lesions versus 34% of placebo patients ($p < 0.007$).

An open, randomized, prospective, comparative study of topical pimecrolimus 1% cream and topical ketoconazole 2% cream in the treatment of seborrheic dermatitis

Koc E, Arca E, Kose O, Akar A. J Dermatolog Treat 2009; 20: 4–9.

In this open-label, randomized comparison study, 48 patients received either pimecrolimus 1% cream or ketoconazole 2% cream twice daily for 6 weeks. At 12 weeks both groups achieved

statistically significant reductions in clinical severity scores, with an average decrease of 86.2% and 86.1%, respectively ($p < 0.05$). There was no significant difference between the two groups.

Single-blind, randomized controlled trial evaluating the treatment of facial seborrheic dermatitis with hydrocortisone 1% ointment compared with tacrolimus 0.1% ointment in adults

Papp KA, Papp A, Dahmer B, Clark CS. J Am Acad Dermatol 2012; 67: e11–5.

Thirty patients received either hydrocortisone 1% cream or tacrolimus 0.1% ointment twice daily to symptomatic areas for 12 weeks. Both groups showed improvement in clinical severity, with patients using tacrolimus needing fewer applications of treatment.

Proactive treatment of adult facial seborrheic dermatitis with 0.1% tacrolimus ointment: randomized, double-blind, vehicle-controlled, multicenter trial

Kim TW, Mun JH, Jwa SW, Song M, Kim HS, Ko HC, et al. Acta Derm Venereol 2013; 93: 557–61.

In this double-blind, placebo-controlled trial, 75 patients used tacrolimus 0.1% ointment twice daily to stabilize their facial seborrheic dermatitis. They were then randomized to use tacrolimus 0.1% once a week, twice a week, or vehicle twice a week, for 10 weeks. Both treatment groups showed significant improvements in erythema, scaling, and pruritus compared with baseline ($p < 0.001$) with lower recurrence rates compared with vehicle ($p < 0.005$).

Third-Line Therapies

• Oral terbinafine	A
• Oral itraconazole	B
• Metronidazole gel	B
• Phototherapy	C
• Benzoyl peroxide	C
• Topical terbinafine	C

Oral terbinafine in the treatment of multisite seborrheic dermatitis: a multicenter, double-blind placebo-controlled study

Vena GA, Micala G, Santoianni P, Cassano N, Peruzzi E. Int J Immunopathol Pharmacol 2005; 18: 745–53.

One hundred and seventy-four patients with seborrheic dermatitis were randomized to receive either terbinafine 250 mg once daily or placebo for 6 weeks. Terbinafine was statistically more effective at achieving 50% improvement than placebo in nonexposed sites (70% vs. 45%) and in achieving patient satisfaction (66% vs. 40%). There was no statistical difference in patients with lesions on exposed sites.

Efficacy of oral itraconazole in the treatment and relapse prevention of moderate to severe seborrheic dermatitis: a randomized, placebo-controlled trial

Ghodsi SZ, Abbas Z, Abedeni R. Am J Clin Dermatol 2015; 16: 431–7.

In this double-blind, placebo-controlled trial, 68 patients with moderate/severe seborrheic eczema received itraconazole 200 mg once daily or placebo daily for 1 week and then for the first 2 days of the month for 3 months. The treatment group showed a more

significant clinical improvement ($p < 0.023$) and lower relapse rates compared with placebo ($p = 0.003$) with response rates of 93.8%, 87.5%, and 93.1% at the end of 2 weeks, 1 month, and 4 months.

Metronidazole 0.75% gel vs. ketoconazole 2% cream in the treatment of facial seborrheic dermatitis: a randomized, double blind study

Seckin D, Gurbuz O, Akin O. J Eur Acad Dermatol Venereol 2007; 21: 345–50.

Sixty patients with facial seborrheic dermatitis used either 0.75% metronidazole gel (with ketoconazole cream as vehicle) or 2% ketoconazole cream (with metronidazole gel as vehicle) for 4 weeks. Around 80% improvement was noted in both groups, with no statistical difference.

Narrow-band ultraviolet B (TL-01) phototherapy is an effective and safe treatment option for patients with severe seborrhoeic dermatitis

Pirkhammer D, Seeber A, Honigsmann H, Tanew A. Br J Dermatol 2000; 143: 964–8.

Eighteen patients were treated three times weekly until complete clearing or to a maximum of 8 weeks. Six showed complete clearance and 12 marked improvement.

Benzoyl peroxide in seborrheic dermatitis

Bonnetblanc JM, Bernard P. Arch Dermatol 1986; 122: 752.

Twenty-eight of 30 patients showed improvement with 1 week's use of 2.5% benzoyl peroxide preparation. All relapsed within 2 to 12 weeks of stopping treatment.

Efficiency of terbinafine 1% cream in comparison with ketoconazole 2% cream and placebo in patients with facial seborrheic dermatitis

Azimi H, Golphorushan F, Jaberian M, Talghini S, Goldust M. J Dermatolog Treat 2013 [Epub ahead of print].

Ninety patients were randomized to use terbinafine 1% cream, ketoconazole 2% cream, or vehicle twice daily for 4 weeks. Both treatment groups showed a significant improvement in clinical severity scores compared with vehicle ($p = 0.003$). No significant difference was found between the two active treatments ($p > 0.05$).

Scalp Disease

First-Line Therapies

• Ketoconazole shampoo	A
• Ciclopirox shampoo	A
• Zinc pyrithione shampoo	A

Topical antiinflammatory agents for seborrhoeic dermatitis of the face or scalp

Kastarinen H, Oksanen T, Okokon EO, Kiviniemi VV, Airola K, Jyrkkä J, et al. Cochrane Database Syst Rev 2014; 5: CD009446.

Successful treatment and prophylaxis of scalp seborrhoeic dermatitis and dandruff with 2% ketoconazole shampoo: results of a multicenter, double-blind, placebo-controlled trial

Peter RU, Richarz-Barthauer U. Br J Dermatol 1995; 132: 441–5.

Five hundred seventy-five patients with moderate to severe scalp seborrheic dermatitis and dandruff were treated with ketoconazole 2% shampoo twice weekly for 2 months, producing clearance in 88%. Three hundred twelve responders were then randomized to active treatment or placebo once weekly. There were fewer relapses in the ketoconazole prophylactic treatment group after 6 months (47% vs. 19%).

Treatment and prophylaxis of seborrheic dermatitis of the scalp with antipityrosporal 1% ciclopirox shampoo

Shuster S, Meynadier J, Kerl H, Nolting S. Arch Dermatol 2005; 141: 47–52.

In this double-blind, vehicle-control trial, 949 patients received ciclopirox 1% shampoo either twice or once weekly or vehicle. After 4 weeks responders were randomized for maintenance therapy with

one of the three regimens for a further 12 weeks. At 4 weeks both ciclopirox regimens were statistically more effective than placebo (response rates 57.9% vs. 45.4% vs. 31.6%). During the maintenance phase relapse rates were significantly lower for both active regimens compared with placebo (14.9% vs. 22.1% vs. 35.5%).

A multicenter randomized trial of ketoconazole 2% and zinc pyrithione 1% shampoos in severe dandruff and seborrheic dermatitis

Piérard-Franchimont C, Goffin V, Decroix J, Piérard GE. Skin Pharmacol Appl Skin Physiol 2002; 15: 434–41.

In this 4-week, open-label, randomized trial, 331 patients with either seborrheic dermatitis or dandruff were randomized to either twice-weekly ketoconazole 2% shampoo or at least twice-weekly zinc pyrithione 1% shampoo. Both groups showed clinical benefit with reductions in dandruff severity of 73% and 61%, respectively.

Second-Line Therapies

• Propylene glycol lotion	A
• Potent/super potent topical corticosteroids	A
• Miconazole	A
• Selenium sulfide shampoo	C

Propylene glycol in the treatment of seborrhoeic dermatitis of the scalp: a double-blind study

Faergemann J. Cutis 1988; 42: 69–71.

Thirty-nine patients with scalp seborrheic dermatitis were treated in a double-blind controlled study with 15% propylene glycol in a base of 50% ethanol and 35% water or vehicle alone: 89% in the group treated with propylene glycol showed healing, compared with 32% in the control group.

A randomized, double-blind, placebo-controlled trial of

ketoconazole 2% shampoo versus selenium sulfide 2.5% shampoo in the treatment of moderate to severe dandruff

Danby FW, Maddin WS, Margeson LJ, Rosenthal D. J Am Acad Dermatol 1993; 29: 1008–12.

A total of 236 patients were included in the study. Both medicated shampoos were statistically better than placebo in treating scaling and itching. However, ketoconazole was superior to selenium shampoo.

Seborrhoeic dermatitis and *Pityrosporum orbiculare*: treatment of seborrhoeic dermatitis of the scalp with miconazole-hydrocortisone (Daktacort), miconazole and hydrocortisone

Faergemann J. Br J Dermatol 1986; 114: 695–700.

In this double-blind, randomized, controlled study, 70 patients received 2% miconazole base and 1% hydrocortisone (Daktacort), 2% miconazole base, or 1% hydrocortisone daily for 3 weeks. The drugs were incorporated into a solution of 60% ethyl alcohol, 10% propylene glycol, and purified water. After 3 weeks responders moved to maintenance therapy with the same agent for a further 3 weeks. Nonresponders continued with daily application. All three groups showed reduced organism culture and clinical improvement with 82.6%, 65.2%, and 29.1% deemed clear in each group.

Multicenter, double-blind, parallel group study investigating the noninferiority of efficacy and safety of a 2% miconazole nitrate shampoo in comparison with a 2% ketoconazole shampoo in the treatment of seborrhoeic dermatitis of the scalp

Buechner SA. J Dermatolog Treat 2014; 25: 226–31.

In this randomized, double-blind, comparative, parallel-group, multicenter study, 274 patients used either miconazole nitrate 2% shampoo or ketoconazole 2% shampoo twice weekly for 4 weeks. Miconazole was found to be noninferior to ketoconazole.

Efficacy of betamethasone valerate 0.1% thermophobic foam in seborrhoeic dermatitis of the scalp: an open-label, multicenter, prospective trial on 180 patients

Milani M, Antonio Di Molfetta S, Gramazio R, Fiorella C, Frisario C, Fuzio E, et al. Curr Med Res Opin 2003; 19: 342–5.

In this open-label trial, 180 patients were treated with 2 g of betamethasone 17-valerate 0.1% foam daily for 15 days and then every other day for 15 days. At 4 weeks there was a statistically significant clinical improvement. Eighty-five percent of patients

preferred the betamethasone foam to previous treatments.

Efficacious and safe management of moderate to severe scalp seborrhoeic dermatitis using clobetasol propionate shampoo 0.05% combined with ketoconazole shampoo 2%: a randomized, controlled study

Ortonne JP, Nikkels AF, Reich K, Ponce Olivera RM, Lee JH, Kerrouche N, et al. Br J Dermatol 2011; 165: 171–6.

This investigator-blind, randomized, controlled trial had four arms of treatment: ketoconazole 2% shampoo twice weekly, clobetasol propionate 0.05% shampoo twice weekly, alternating ketoconazole and clobetasol twice weekly, or ketoconazole four times weekly alternating with clobetasol twice weekly for 4 weeks. This was followed by a 4-week maintenance phase where all patients received weekly ketoconazole and a further 4-week follow-up phase. In total 326 patients were included. All groups demonstrated clinical improvement, and all three clobetasol-containing regimens were significantly more effective than ketoconazole alone. Of these the twice weekly alternating clobetasol and ketoconazole regimen was the most effective.

The authors would like to stress that potent and superpotent steroids may not be considered suitable for long-term use.

Seborrheic keratosis

Richard J. Motley

Seborrheic keratosis is a benign, exophytic, warty, pigmented growth of the skin surface that becomes increasingly common with age, with the degree of pigmentation varying with skin type from light gray to intense black. Found on all areas of the body, but mainly on the trunk, often at sites of pressure, it is a cosmetic nuisance and rarely a cause for diagnostic confusion. Several variants exist and are described later. Caution should be exercised, however, when

considering this diagnosis for lesions around the genitalia where genital warts are a more likely diagnosis and appear morphologically similar.

Management Strategy

Many patients present with seborrheic keratoses because of concern about possible melanoma, and reassurance may be all that is required. Occasionally the lesion can become “irritated” and show erythema, crusting, and itching. In this case the appearance may resemble squamous cell carcinoma. Any significant change in a lesion previously diagnosed as seborrheic keratosis—such as the development of several colors, rapid increase in size, or bleeding—should prompt a reconsideration of the diagnosis, as true melanocytic nevi and even malignant melanoma may occasionally have a seborrheic keratosis–like appearance

Where treatment is requested there are several options, and the choice will depend on patient and physician preference. *Surgical excision*, although effective, is never the treatment of choice unless there is real concern about the possibility of a malignant melanoma. When the diagnosis is in doubt, material should be taken for histologic examination, preferably by a *shave* or *tangential biopsy* technique or by *sharp curettage*. Blunt curettage provides poor material for histologic assessment. *Electrodesiccation* or *cautery* is very effective at softening the lesion and separating it at the dermoepidermal junction, allowing it to be wiped away with cotton gauze. Electrodesiccation may also be used after shave excision to treat any tissue remnants. With all these treatments the aim is to remove the lesion but little of the underlying skin surface.

Cryotherapy using a liquid nitrogen spray is an alternative treatment. Liquid nitrogen is sprayed onto the lesion until it is frozen and then continued for 5 to 10 seconds. It is done without local anesthesia because freezing reduces sensation of pain, and this can be an advantage when treating multiple lesions. After a day or two the treated lesion blisters and crumbles away. The underlying wound heals over several days and is often quite exudative, requiring daily cleansing by the patient. Overall the recovery period is longer and the wound slower to heal than after curettage and cautery. After cryotherapy, hypopigmentation may occur, and for this reason it is not recommended in black people.

Seborrheic Keratosis Variants

Senile or “solar” lentigines can be considered flat versions of the seborrheic keratosis. Sometimes referred to as *age or liver spots*, these small pigmented papules and plaques are more commonly seen on areas of frequent sun exposure, such as the face and dorsa of the hands. Their true nature can be recognized by the slight velvety texture to the lesional surface, which is best seen with tangential lighting. This indicates that the lesion is not a true lentigo but a superficial keratosis. These lesions are amenable to very minor treatments. Topical *tretinoin* cream can be effective. Other treatments include light abrasion with an *exfoliating cream*, *light dermabrasion* or *laser resurfacing*, *cryotherapy*, or *chemical peels* using trichloroacetic acid or phenol. A favorite treatment is minimal cautery followed by curettage with a cotton gauze swab. This leaves an erythematous superficial wound that heals rapidly.

Dermatosis papulosa nigra is commonly seen on the cheeks of black adults. These small seborrheic warts are easily treated by light cautery or electrodesiccation followed by cotton gauze curettage, but patients should be warned about the possibility of hyperpigmentation.

Stucco keratoses are small, grayish-white seborrheic keratoses that are typically found on the forearms and lower legs and are easily removed with curettage without bleeding. The edge of these lesions is often curled up away from the skin surface.

Giant seborrheic keratoses are large lesions, usually found on the scalp, and are often several centimeters in diameter.

Multiple Seborrheic Keratoses

Seborrheic keratoses may have a familial tendency, especially when multiple. It is these patients who are often the most challenging to treat and also the most affected by their condition. Patients often present with multiple lesions and request their complete removal.

The sudden onset of multiple seborrheic keratoses may be associated with underlying malignancy (the sign of Leser–Trélat) and should prompt a full clinical examination for underlying malignancy. Eruptive seborrheic keratoses may also occur after widespread eczema (so-called *Williams warts*) and have been associated with adalimumab use.

Specific Investigation

- Consider the sign of Leser-Trélat and investigate for underlying malignancy

Sign and pseudosign of Leser-Trélat: case reports and a review of the literature

Husain Z, Ho IK, Hantash BM. J Drugs Dermatol 2013; 12: 79–87.

The sign of Leser-Trélat is a rare paraneoplastic sign characterized by a sudden eruption of multiple seborrheic keratoses or their rapid increase in size. Its association with malignant acanthosis nigricans, seen in 35% of patients, is one of several of its features that support its legitimacy as a true paraneoplastic disorder. Gastric adenocarcinoma was the most frequently associated malignancy. In over 68% of cases the sign preceded the diagnosis of malignancy. Similar, nonmalignancy-associated eruptions are referred to as the *pseudosign of Leser-Trélat*.

Eruptive seborrheic keratoses associated with adalimumab use

Eastman KL, Knezevich SR, Raugi GJ. J Dermatol Case Rep 2013; 7: 60–3.

Eruptive seborrheic keratoses were associated with adalimumab therapy for rheumatoid arthritis and resolved when the drug was discontinued.

First-Line Therapies

• Reassurance	E
• Curettage and cautery	B
• Cryotherapy	B

Effectiveness of cryosurgery vs. curettage in the treatment of seborrheic keratoses

Wood LD, Stucki JK, Hollenbeak CS, Miller JJ. JAMA Dermatol 2013; 149: 108–9.

This pilot study showed that the majority of patients preferred cryotherapy over curettage at both the 6-week and greater-than-12-month survey points.

Treatment of dermatosis papulosa nigra in 10 patients: a comparison trial of electrodesiccation, pulsed dye laser, and curettage

Garcia MK, Azari R, Eisent DB. Dermatol Surg 2010; 36: 1967–72.

Pulsed dye laser treatment offered no advantage compared with electrodesiccation or curettage for dermatosis papulosa nigra

Goetze S, Ziemer M, Lipman RD, Elsner P. Dermatol Surg 2006; 32: 661–8.

Hydrocolloid dressings produced superior healing of superficial wounds after curettage of seborrhoeic keratoses.

Second-Line Therapies

• Chemical peels for smaller, superficial lesions and dermatosis papulosa nigra	C
• Lasers (pulsed CO ₂ , erbium:YAG)	C

Focal trichloroacetic acid peel method for benign pigmented lesions in dark-skinned patients

Chun EY, Lee JB, Lee KH. Dermatol Surg 2004; 30: 512–16.

After cleansing the skin with alcohol, 65% trichloroacetic acid was applied focally to seborrheic keratoses using a sharpened wooden applicator to create evenly frosted spots on each lesion. Crusts separated from the skin with gentle washing after 4 to 7 days, and healing was complete 10 to 14 days later. Twenty-three patients required a mean of 1.5 treatments, and in 57% of these the results were rated as excellent.

Use of a long-pulse alexandrite laser in the treatment of

superficial pigmented lesions

Trafeli JP, Kwan JM, Meehan KJ, Domankevitz Y, Gilbert S, Malomo K, et al. *Dermatol Surg* 2007; 33: 1477–82.

Patients with solar lentigines were treated with a long-pulse alexandrite laser (755-nm wavelength). Optimal settings were spot size 10 mm, pulse duration 3 ms, and fluence 22 J/cm² (without skin cooling). The authors advocate undertaking some initial test spots and observing the result after 10 minutes before proceeding to treat an entire area. The desired end point is a slight darkening of each lesion and/or perilesional erythema. Treated lesions darken and crust and fall off within about 10 days.

Treatment of verruca vulgaris, seborrheic keratoses, lentigines, and actinic cheilitis. Clinical advantage of the CO₂ laser superpulsed mode

Fitzpatrick RE, Goldman MP, Ruiz-Esparza J. *J Dermatol Surg Oncol* 1994; 20: 449–56.

Continuous and superpulsed CO₂ lasers were compared in their effect on a variety of lesions, including seborrheic keratoses. Ideal parameters prevent unwanted thermal damage.

Ablation of cutaneous lesions using an erbium:YAG laser

Khatri KA. *J Cosmet Laser Ther* 2003; 5: 150–3.

Erbium:YAG laser was used to remove multiple benign skin lesions and found to be safe and effective for this purpose.

532-nm diode laser treatment of seborrhoeic keratoses with color enhancement

Gulbertson GR. *Dermatol Surg* 2008; 34: 525–8.

A red color marker was applied to seborrheic keratoses to enhance the laser absorption before treatment with a 532-nm diode laser; 93% of lesions responded completely.

Third-Line Therapy

• 5-Fluorouracil

E

Giant seborrheic keratosis on the frontal scalp treated with topical fluorouracil

Tsuji T, Morita A. J Dermatol 1995; 22: 74–5.

An unusual giant scalp seborrheic keratosis was successfully treated with topical fluorouracil.

Use of a keratolytic agent with occlusion for topical treatment of hyperkeratotic seborrheic keratoses

Burkhart CG, Burkhart CN. Skinmed 2008; 1: 15–8.

A topical 50% urea-containing product applied under occlusion was combined with superficial scraping to remove hyperkeratotic seborrheic keratoses on the trunk and extremities.

Sporotrichosis

Mahreen Ameen, and Wanda Sonia Robles

Sporotrichosis is a deep, cutaneous fungal infection caused by *Sporothrix schenckii*, a rapidly growing, dimorphic, saprophytic fungus found in soil and plant matter. It can affect both humans and animals and is prevalent worldwide, but is more common in the tropics. Disseminated infection, particularly to osteoarticular structures and viscera, is a risk in the immunocompromised and an emerging problem in those with advanced HIV infection. Infection is usually sporadic, but outbreaks may occur due to contaminated soil and wood. Cutaneous lesions develop after traumatic inoculation of *S. schenckii*. Infection is therefore more common in some occupations

such as horticulturists, carpenters, and miners. Fifteen percent of cases occur in children less than 10 years of age. The initial lesion appears at the site of injury as an erythematous, ulcerated, or verrucous nodule. Lesions can be localized and are known as *fixed-type sporotrichosis*. The more common presentation is the lymphocutaneous form, where there is nodular lymphangitic spread.

Management Strategy

Although there have been cases describing the spontaneous remission of sporotrichosis, it is common practice to treat. Treatment includes local measures (thermotherapy), saturated solution of potassium iodide (SSKI), azoles, terbinafine, and amphotericin B. Historically, uncomplicated lymphangitic and fixed forms of sporotrichosis have been treated with high-dose SSKI initiated with 5 drops three times daily and increased as tolerated to 10 to 50 drops three times daily (equivalent to 250 mg to 1 g three times daily). Treatment is continued for 3 to 4 weeks after clinical cure. The mechanism of action of potassium iodide is not known, but it is highly effective, with reported cure rates ranging from 80% to 100%. It is also inexpensive and is the first-line treatment for sporotrichosis in most developing countries. However, it is inconvenient to administer, and side effects are common, although not serious, and include metallic taste, nausea, abdominal pain, and salivary gland enlargement.

Itraconazole is first-line therapy in countries where it is affordable. It should be initiated at a loading dose of 200 mg three times daily for 3 days followed by 100 to 400 mg daily. Cure rates for cutaneous and lymphocutaneous infection are high, generally 90% to 100%.

Terbinafine (250–1000 mg daily) produces similar efficacy.

Fluconazole (400–800 mg daily) therapy gives response rates of 63% to 71% and therefore is recommended for second-line therapy only.

Ketoconazole is ineffective for the treatment of sporotrichosis.

There are no clinical trials to guide therapy for disseminated or meningeal sporotrichosis, which can occur with immunosuppression. On the basis of case reports, parenteral amphotericin B (AmB) is the preferred treatment (AmB deoxycholate 0.7 mg/kg daily, or as a lipid formulation 3.0–5.0 mg/kg daily). A lipid formulation of AmB is recommended for meningeal infection. After AmB induction therapy, itraconazole (200 mg twice daily) is given as maintenance therapy. Thermotherapy (using infrared and far infrared wavelengths to heat

tissues to 42°–43°C) is known to be effective, although there are few reports of its use. It has a useful role when systemic therapies are contraindicated. Clinical data demonstrating the potential of cryotherapy as an adjuvant to systemic therapy are limited.

Specific Investigations

- Culture
- Histology
- Serology for HIV infection (where relevant)

Direct microscopy of infected material is futile because the infective organisms are scarce in tissue. Culture is the most sensitive means of diagnosis and is characteristically rapid, with growth usually seen within 1 week in 90% of cases. In the remaining 10% it may take up to 4 weeks to achieve a positive result on Sabouraud agar culture. The diagnosis is confirmed by demonstrating dimorphism, or conversion to the yeast phase. Suitable material for culture may include lesion swab, aspirate, or biopsy. Data for polymerase chain reaction (PCR) are limited, and this technique requires further clinical validation.

The impact of sporotrichosis in HIV-infected patients: a systematic review

Moreira JA, Freitas DF, Lamas CC. *Infection* 2015; 43: 267–76.

This is a systematic review of reported cases of HIV-associated sporotrichosis found via PubMed (1984–2013). A total of 39 papers were included and 58 patients' data analyzed. A reported 56.9% cases were from Brazil and 31% from the United States. The median CD4 cell count was 97 cells/mm.³ The most common clinical forms were disseminated and disseminated cutaneous, affecting 56.9% and 17.5% of patients, respectively. Mortality was 30% and significantly higher in those with central nervous system involvement and death.

In this group of patients amphotericin B was usually the drug of choice, and itraconazole was used as maintenance therapy.

Immune reconstitution inflammatory syndrome in HIV and sporotrichosis coinfection: report of two cases and review of the literature

Lyra MR, Nascimento ML, Varon AG, Pimentel MI, Antonio Lde F,

Saheki MN, et al. Rev Soc Bras Med Trop 2014; 47: 806–9.

This is a report of two cases of patients with immune reconstitution inflammatory syndrome (IRIS) associated with cutaneous disseminated sporotrichosis and HIV coinfection. The patients received amphotericin and itraconazole combination treatment for sporotrichosis. However, 4 and 5 weeks after commencing antiretroviral therapy (ART), both patients experienced clinical exacerbation of skin lesions, despite increased T CD4+ cells and decreased viral load. They required treatment with several-month courses of systemic corticosteroids together with continued antifungal therapy. The authors noted that disease relapsed when corticosteroids were discontinued prematurely.

The risk of IRIS is higher in HIV-infected patients with low baseline CD4 counts before initiation of ART. In this group of patients the authors recommend close follow-up of patients at risk of IRIS and recommend prolonged corticosteroid treatment if necessary.

Sporotrichosis: an overview and therapeutic options

Mahajan VK. Dermatol Res Pract 2014; 2014: 272376.

This review reports that saturated solution of potassium iodide is generally used as a first-line treatment choice for uncomplicated cutaneous sporotrichosis in resource-limited countries. Itraconazole has very good efficacy and is recommended for the treatment of all forms of sporotrichosis. Terbinafine has demonstrated lower efficacy compared with itraconazole. Amphotericin B is used initially for the treatment of severe or systemic disease, during pregnancy, and in immunosuppressed patients followed by itraconazole prophylaxis if indicated.

Potassium iodide in dermatology: a 19th century drug for the 21st century: uses, pharmacology, adverse effects, and contraindications

Sterling JB, Heymann WR. J Am Acad Dermatol 2000; 43: 691–7.

This article reviews the pharmacology and adverse effects of potassium iodide as a therapeutic agent. It discusses contraindications to its use, which include a history of thyroid or kidney disease and pregnancy.

Disseminated sporotrichosis associated with treatment with immunosuppressants and tumor necrosis factor-alpha

antagonists

Gottlieb GS, Lesser CF, Holmes KK, Wald A. Clin Infect Dis 2003; 37: 838–40.

A male adult patient developed disseminated infection after treatment with multiple immunosuppressants, including etanercept and infliximab for inflammatory arthritis. He was subsequently treated with a lipid formulation of amphotericin B.

With the increasing availability and use of anti-TNF- α agents, there is an increased risk of sporotrichosis presenting with disseminated infection rather than indolent cutaneous lesions only.

First-Line Therapies

• Itraconazole	A
• Terbinafine	A
• Potassium iodide	B
• Amphotericin B (for disseminated sporotrichosis)	E

Treatment of cutaneous sporotrichosis with itraconazole: study of 645 patients

de Lima Barros MB, Schubach AO, de Vasconcellos Carvalhaes de Oliveira R, Martins EB, Teixeira JL, Wanke B. Clin Infect Dis 2011; 52: e200–6.

This is the largest study of sporotrichosis (68.1% with lymphocutaneous form and 23.1% with fixed form) treated with itraconazole 50 to 400 mg/day. There was a 94.6% cure rate in the 619 patients who completed treatment (547 with 100 mg/day, 59 with 200–400 mg/day, and 4 children with 50 mg/day). Treatment was given until cure, and the median treatment duration was 12 weeks (range 2–64 weeks). Lymphocutaneous and disseminated forms required approximately 2 weeks longer to achieve cure than did the fixed form. The most frequent clinical adverse effect was nausea. A reported 12.4% required further courses of treatment because of relapse. These were mainly those treated with the lower dose of 100 mg/day. One patient, despite dose escalation of itraconazole to 400 mg/day, failed

and was cured only after switching to potassium hydroxide.

This study demonstrated that a dose of 100 mg daily is highly effective in the vast majority of patients with fixed or lymphocutaneous disease, although it was sometimes associated with a higher risk of relapse. This is important as it makes itraconazole a more affordable option in resource-poor regions. This report has also demonstrated that potassium iodide can be more efficacious than itraconazole, although there have been no comparative studies.

Efficacy and safety of itraconazole pulses vs. continuous regimen in cutaneous sporotrichosis

Song Y, Zhong SX, Yao L, Cai Q, Zhou JF, Liu YY et al. *J Eur Acad Dermatol Venereol* 2011; 25: 302–5.

This randomized controlled trial comparing pulse itraconazole 200 mg twice daily for 1 week every month ($n = 25$, mean course of treatment 2.65 ± 0.81 pulses) with continuous itraconazole 100 mg twice daily ($n = 25$, mean course of treatment 2.8 ± 2.33 months) demonstrated cure rates at 48 weeks of 81.8% and 95.8%, respectively. Side effects in the pulse therapy and continuous therapy groups were 4.5% versus 16.7%, respectively.

Pulse therapy has the advantages of lower cost and fewer adverse effects, although this small trial demonstrates higher efficacy with the continuous itraconazole regimen.

Cutaneous sporotrichosis in Himachal Pradesh, India

Mahajan VK, Sharma NL, Sharma RC, Gupta ML, Garg G, Kanga AK. *Mycoses* 2005; 48: 25–31.

One hundred and three cases of the lymphocutaneous and fixed cutaneous varieties of sporotrichosis are described during the period 1990 to 2002. Potassium iodide was used as first-line treatment, and in 93% of patients healing of lesions occurred in 4 to 32 weeks (average 8.7 weeks) without significant side effects. Itraconazole was used in 12 patients and was also highly effective.

This study demonstrates that the efficacy of potassium iodide is comparable to itraconazole.

Terbinafine (250 mg/day): an effective and safe treatment of cutaneous sporotrichosis

Francesconi G, Valle AC, Passos S, Reis R, Galhardo MC. *J Eur Acad Dermatol Venereol* 2009; 23: 1273–6.

Of 50 cases of sporotrichosis treated with terbinafine 250 mg daily, 96% ($n = 48$) were cured after a mean treatment period of 14 weeks with no recurrence after a mean follow-up period of 37 weeks. One patient discontinued drug therapy because of the development of a skin rash.

This study demonstrates that standard doses of terbinafine have adequate efficacy and that sporotrichosis does not generally require high-dose terbinafine therapy. The authors also point out that one of the advantages of terbinafine is that it has fewer drug–drug interactions than does itraconazole.

Comparative study of 250 mg/day terbinafine and 100 mg/day itraconazole for the treatment of cutaneous sporotrichosis

Francesconi G, Francesconi do Valle AC, Passos SL, de Lima Barros MB, de Almeida Paes R, Curi AL, et al. *Mycopathologia* 2011; 171: 349–54.

Itraconazole 100 mg daily and terbinafine 250 mg given to 249 and 55 patients, respectively, with culture-proven sporotrichosis demonstrated almost equal cure rates in both groups of 92% to 93% within a similar mean period (11.5–11.8 weeks). Adverse effects were equally frequent with both drugs, occurring in approximately 7% of those treated and were generally mild except in two patients receiving itraconazole who had to discontinue treatment.

This study provides further evidence for the efficacy of lower doses of itraconazole or terbinafine therapy. It also demonstrates that terbinafine is perhaps better tolerated.

Second-Line Therapies

• Fluconazole	B
• Thermotherapy	D
• Cryotherapy	D

Treatment of lymphocutaneous and visceral sporotrichosis with fluconazole

Kauffman CA, Pappas PG, McKinsey DS, Greenfield RA, Perfect JR, Cloud GA, et al. Clin Infect Dis 1996; 22: 46–50.

This clinical trial involved 14 patients with lymphocutaneous infection and 16 with osteoarticular or visceral sporotrichosis. Eleven of the 30 patients had previously been treated with other forms of antifungal therapy without success. Most patients were treated with fluconazole 400 mg/day. Four patients received fluconazole 200 mg/day, and another four received 800 mg/day. Seventy-one percent of patients (10/14) with lymphocutaneous sporotrichosis were cured. However, only 31% (5/16) with osteoarticular or visceral sporotrichosis responded to treatment.

This paper concluded that fluconazole is only modestly effective for the treatment of sporotrichosis and perhaps should be considered second-line therapy in patients who are unable to take itraconazole.

Hyperthermic treatment of sporotrichosis: experimental use of infrared and far infrared rays

Hiruma M, Kawada A, Noguchi H, Ishibashi A, Conti Díaz IA. Mycoses 1992; 35: 293–9.

Pocket warmers and infrared and far infrared rays were used to treat 14 cases of sporotrichosis, 7 in children and 7 in adults. Heat was applied daily to the lesions, and the devices warmed tissues to 42°C to 43°C. All lesions treated with pocket warmers were facial lesions in children. Infrared and far infrared rays generated more heat than pocket warmers, allowing the length of a single treatment to be

reduced by three quarters to only a single 15-minute treatment daily. The overall cure rate was 71%.

The efficacy for this form of treatment has not been satisfactorily evaluated. However, it has an important role in the treatment of infection in those who are unable to take systemic therapy.

Cryosurgery as adjuvant therapy in cutaneous sporotrichosis

Ferreira CP, Galhardo MC, Valle AC. Braz J Infect Dis 2011; 15: 181–3.

Nine patients with one or two lesions of sporotrichosis that persisted despite completing drug therapy with either itraconazole, potassium iodide, or terbinafine were then treated with cryotherapy given monthly as two cycles of 15 seconds with a halo of 5 mm. The patients required one to four cryotherapy sessions to achieve cure.

The study has demonstrated the efficacy of cryotherapy and its ability to speed up disease resolution. By acting as an adjunctive therapy, it has the potential to decrease the duration of chemotherapy.

Guidelines

Clinical Practice Guidelines for the Management of Sporotrichosis: 2007 Update by the Infectious Diseases Society of America

Kauffman CA, Bustamante B, Chapman SW, Pappas PG. Clin Infect Dis 2007; 45: 1255–65.

For cutaneous and lymphocutaneous infection in developed countries, first-line recommended therapy is with itraconazole 200 mg daily, which is continued for 2 to 4 weeks after all lesions have resolved. Usually a 3- to 6-month course of treatment is recommended. Patients who fail to respond can be given either high-dose itraconazole 200 mg twice daily, terbinafine 500 mg twice daily, or SSKI initiated at a dose of 5 drops three times daily and increased as tolerated to 40 to 50 drops thrice daily. Children can be treated with the same drugs at a dose of 6 to 10 mg/kg for itraconazole (maximum 400 mg daily) and a maximum of 1 drop/kg of SSKI. Fluconazole should only be used in patients who cannot tolerate any of these treatments. Thermotherapy can be used for fixed lesions in those in whom oral therapy is contraindicated, such as pregnant women. Amphotericin B is the recommended first-line therapy for severe pulmonary or osteoarticular infection, disseminated, and

meningeal sporotrichosis. After the initial response, itraconazole is recommended as step-down therapy and should be given to complete a total of at least 12 months of therapy. Amphotericin B is also the drug of choice for severe infection in pregnancy.

Future updated guidelines will need to incorporate recent data demonstrating the efficacy of lower doses of itraconazole and terbinafine for sporotrichosis.

Squamous cell carcinoma

Bassel H. Mahmoud, and Suzanne M. Olbricht

Cutaneous squamous cell carcinoma (SCC) originates from keratinizing cells of the epidermis or its appendages. Most commonly it presents as an erythematous papule or nodule with scale and crust, but it may also be ulcerated, hyperpigmented, or surmounted by a cutaneous horn.

SCC is not only the second most common type of skin cancer, but also the second most common malignancy of any kind in the United States. Incidence varies geographically, with higher rates at lower latitudes. The lifetime risk for SCC is increasing worldwide, escalating 50% to 300% in the last 3 decades. Cumulative ultraviolet

light (UVL) exposure is the most common cause of SCC of the skin, which explains why the majority of SCCs occur on the head, neck, and extremities, areas of maximum sun exposure. Depletion of atmospheric ozone and longer life expectancy contribute to larger cumulative exposures. Other risk factors include use of tanning beds, chemical carcinogens, and immunosuppressive drug therapy; chronic scar; chronic dermatoses such as epidermolysis bullosa; human papilloma virus (HPV) infection; and genodermatoses such as xeroderma pigmentosum. A person with one SCC is at high risk for developing more SCCs as well as other skin cancers.

Management Strategy

The importance of prevention by educating everyone from an early age about this hazard of solar UV exposure cannot be overemphasized.

The goals of treatment of primary cutaneous SCC are to completely remove the tumor, to minimize the risk of metastasis and recurrence, to restore normal function after treatment, and to provide the best possible cosmetic outcome. Preoperative workup includes history of prior treatment, clinical size of the lesion, and an accurate histopathologic diagnosis. Physical examination should include regional lymph node palpation. A shave biopsy is generally sufficient for epidermal and deep dermal inspection, but punch biopsy to subcutaneous fat or an incisional or excisional biopsy can sometimes provide additional information. For reasons of prognostication, the pathology report should comment on depth of tumor invasion, histologic differentiation, and the presence or absence of sclerosis, single cell infiltration, and neurotropism. Additional laboratory and imaging studies are not generally helpful, although they may be performed when an aggressive high-risk tumor is suspected.

High-risk tumors are recurrent; have a diameter of more than 2 cm; are present on the ear, temple, lip, or anogenital region; or have poor histologic differentiation or other histologic features noted earlier. The most recent American Joint Committee on Cancer (AJCC) and National Comprehensive Cancer Network (NCCN) Guidelines identified criteria for “high-risk” factors for local recurrence or metastases, which included poor differentiation, perineural invasion, and depth of tumor. Immunosuppression also increases risk, notably in transplant recipients.

When choosing therapy, the main consideration is the cure rate; however, every patient should be assessed individually with regard to site and size of the lesion, functional and cosmetic implications of treatment, the patient's general medical condition, ability to return for additional treatment, and the patient's preferences.

Mohs micrographic surgery (MMS) provides the best long-term cure rate and is the treatment of choice for large lesions in critical sites, as well as for high-risk and recurrent SCC, because of its unique method of margin control as well as its tissue-sparing benefits. In this technique marginal, normal-appearing skin is removed as a thin tangential layer around and under the clinically apparent tumor, precisely oriented, horizontally sectioned, and immediately processed as a frozen section for histologic evaluation. This is repeated until all margins are histologically clear. Based on the appropriate use criteria (AUC) developed by the American Academy of Dermatology, American College of Mohs Surgery, American Society for Dermatologic Surgery, and the American Society for Mohs Surgery, MMS is appropriate for all SCCs in the high-risk and intermediate-risk areas; for SCCs 11 mm in diameter or greater in any site; for SCC in situ in areas of chronic inflammation, osteomyelitis, prior radiation, or scar; for locally recurrent and incompletely excised SCC; and for all SCCs in immunosuppressed patients or in patients with genetic syndromes. MMS is also indicated in SCC with aggressive histologic features and those with perineural or perivascular invasion.

Standard surgical excision may be performed for well-circumscribed tumors with diameters less than 2 cm that do not occur on the ears, lips, eyelids, nose, or scalp and do not invade the fat. Surgical margins of 4 to 6 mm are usually adequate to achieve a 95% chance of a cure. Lesions with diameters of 2 cm or greater in low-risk locations may be excised with 10-mm margins, but tissue rearrangement should not be performed until there is pathologic verification of tumor-free margins. The main advantage of excisional surgery over destructive therapy is that there is histologic analysis of the excised tissue specimen.

Electrodesiccation and curettage (ED&C) is considered for the treatment of low-risk, well-differentiated primary SCC and SCC in situ <1 cm in diameter. It involves a sequence of three curette scrapings and electrodesiccations. A margin of 3 to 4 mm around the tumor should be included in the treatment area to ensure complete removal of the tumor. Treated lesions often require several weeks to

heal and may leave a white atrophic or hypertrophic scar that can be cosmetically unappealing. Cosmetically sensitive areas, concave surfaces, and skin prone to keloid formation or poor wound healing should be avoided. Cure rates are highly technique dependent, but range from 80% to 95%.

Cryosurgery is another destructive technique that can be considered for small (<1 cm), low-risk SCC and SCC in situ with cure rates similar to treatment by ED&C if performed properly. Cryosurgery destroys a tumor if it is frozen to -60°C , achievable with timed stages or the use of thermocouples. It leaves a wound that may blister and drain but otherwise heals without complication to a porcelain white atrophic scar. It has the advantage of being fast, simple, and inexpensive, but the success of the procedure is very much operator dependent.

Algorithm for treatment of cutaneous squamous cell carcinoma.

Photodynamic therapy (PDT) involves the application of a photosensitizing agent onto the skin followed by irradiation with a light source. It is approved by the Food and Drug Administration (FDA) for the treatment of actinic keratosis, but other studies using

different treatment regimens have documented some success for the treatment of nonmelanoma skin cancers.

Radiation therapy as a primary treatment modality for SCC is best reserved for those situations in which surgical risk is not acceptable. Because of the potential long-term sequelae, it is not advisable in patients under 60 years old. Treatment is given sequentially over several weeks. Complications include hypopigmentation, telangiectasia, loss of adnexae, radiation dermatitis, and the appearance of a new primary tumor 10 to 20 years later. Radiation therapy is also recommended as adjuvant therapy for SCC with substantial perineural involvement, especially when the involved nerves are 0.1 mm or greater in caliber. Brachytherapy has recently been widely used because of the ability to deliver energy at a high-dose rate, leading to fewer patient visits.

Other options may be useful for specific patients. *Topical therapy* has a low cure rate and is therefore reserved mainly for patients with SCC not amenable to surgical treatment or radiation due to either advanced disease stage or large number of lesions or both; topical therapy includes *imiquimod* or *5-fluorouracil (5-FU) cream*. Some patients with many lesions, particularly on the legs, may be successfully treated with *intralesional methotrexate*, *5-FU*, *bleomycin*, or *interferon (IFN)*. For patients with many lesions who are immunosuppressed, systemic therapy with *retinoids* or *IFN* may be tried, but the results are mixed and there is usually only suppression of growth, not cure.

Systemic treatment for SCC includes *chemotherapy* for metastatic disease. *Cisplatin* has been used alone or in combination with *5-FU*, *methotrexate*, *bleomycin*, or *doxorubicin*. Epidermal growth factor receptor inhibitors, including *cetuximab* and *gefitinib*, have been used off-label to treat metastatic SCC because of the overexpression of epidermal growth factor (EGFR) in some tumors.

Patients with a history of SCC need continued lifelong cutaneous surveillance to monitor for tumor recurrence and metastasis, as well as for new developing lesions, as they are at higher risk of another skin cancer even within 5 years of the first tumor.

Specific Investigations

- Biopsy

- Radiologic examination (PET, MRI, CT, ultrasound) if high-risk tumor
- Sentinel lymph node biopsy (controversial) may be considered for very high-risk tumors

Cutaneous squamous cell carcinoma: a comprehensive clinicopathologic classification: part two

Cassarino DS, Derienzo DP, Barr RJ. J Cutan Pathol 2006; 33: 261–79.

SCC is one of the few cancers where progression from focal nests of atypical cells to in situ disease to invasive carcinoma can be surmised, both clinically and histologically. Invasive SCCs can be categorized into well-, moderately well-, moderately, and poorly differentiated subtypes. Poorly differentiated SCCs have a higher risk of recurrence and metastasis. Invasive SCC may exhibit mixed cell inflammation around the tumor, sclerotic stroma, and perineural infiltration. Histologic subtypes that have an increased risk of recurrence or metastasis are adenoid (acantholytic), desmoplastic spindle cell SCCs, and invasive Bowen disease carcinoma.

Reliability of the histopathologic diagnosis of keratinocyte carcinomas

Jagdeo J, Weinstock MA, Piepkorn M, Bingham S. J Am Acad Dermatol 2007; 57: 279–84.

A prospective blinded study of 3926 specimens reviewed by both pathologists and dermatopathologists showed highest intraobserver agreement for basal cell carcinoma (BCC) and lowest in the categories of invasive SCC, SCC in situ, and actinic keratosis, suggesting the boundaries of these diagnoses are imprecisely defined.

MR imaging of perineural tumor spread

Ginsberg LE. Magn Reson Imaging Clin N Am 2002; 10: 511–25.

Preoperative imaging studies should be obtained when there is suspicion of metastases, bone invasion, or perineural infiltration. Controversy remains regarding the choice of radiologic examination. Computed tomography (CT) is used to image extracapsular spread, central nodal necrosis, skull base, and cartilage invasion. Magnetic resonance imaging (MRI) provides improved imaging of tissue planes and neurotropic tumors. Positron emission tomography (PET) scans can detect metastases in areas of necrosis, dense fibrosis, or scarring

from radiation therapy, whereas CT and MRI can identify soft tissue infiltration and bony erosion.

Impact of radiographic findings on prognosis for skin carcinoma with clinical perineural invasion

Galloway TJ, Morris CG, Mancuso AA, Amdur RJ, Mendenhall WM. Cancer 2005; 103: 1254–7.

When involvement of a large nerve is suspected, an MRI and CT scan should be obtained to evaluate the extent of disease and rule out intracranial involvement.

Evaluation of American Joint Committee on Cancer, International Union Against Cancer, and Brigham and Women's Hospital tumor staging for cutaneous squamous cell carcinoma

Karia PS, Jambusaria-Pahlajani A, Harrington DP, Murphy GF, Qureshi AA, Schmults CD. J Clin Oncol 2014; 32: 327–34.

A comparative evaluation of three tumor (T) staging systems. AJCC and UICC showed that most poor outcomes occurred in low stages (T1/T2), whereas at BWH, incidences of poor outcomes were low for low-stage tumors (T1/T2a) and higher for higher-stage tumors (T2b/T3).

High-risk cutaneous squamous cell carcinoma and the emerging role of sentinel lymph node biopsy: a literature review

Navarrete-Dechent C, Veness MJ, Droppelmann N, Uribe P. J Am Acad Dermatol 2015; 73: 127–37.

Evidence supports considering sentinel lymph node biopsy (SLNB) in SCC classified as AJCC-7 T2 larger than 2 cm in diameter. Patients with other high-risk factors such as recurrent SCC and immunosuppressed patients should also be included in clinical trials evaluating the utility of SLNB in SCC.

First-Line Therapies

• Mohs micrographic surgery	B
• Standard excision	B
• Curettage and electrodesiccation	B
• Cryosurgery	B
• Radiation therapy	B

Mohs surgery for squamous cell carcinoma

Belkin D, Carucci JA. *Dermatol Clin* 2011; 29: 161–74.

MMS provides the highest cure rates for both primary and recurrent tumors. The 5-year recurrence rates for primary tumors of the skin were 7.9% for non-Mohs modalities and 3.1% for MMS. For primary SCC of the lip, 5-year recurrence rates were 10.5% for non-Mohs modalities and 2.3% for MMS. For primary SCC of the ear, 5-year recurrence rates were 18.7% for non-Mohs modalities and 5.3% for MMS.

High recurrence rates of squamous cell carcinoma after Mohs' surgery in patients with chronic lymphocytic leukemia

Mehrany K, Weenig RH, Pittelkow MR, Roenigk RK, Otley CC. *Dermatol Surg* 2005; 31: 38–42.

Patients with immunosuppression can have a higher recurrence rate and require close surveillance.

Surgical margins for excision of primary squamous cell carcinoma

Brodland DG, Zitelli JA. *J Am Acad Dermatol* 1992; 27: 241–8.

Based on a prospective study of subclinical microscopic tumor extension, it was recommended that minimal margins of 4 mm be taken around clinical borders of SCC. Margins of at least 6 mm were proposed for tumors ≥ 2 cm, histologic grade ≥ 2 , with invasion of subcutaneous tissue, and/or location in high-risk areas.

The treatment of skin cancer. A statistical study of 1341 skin tumors comparing results obtained with irradiation, surgery, and curettage followed by electrodesiccation

Freeman RG, Knox JM, Heaton CL. Cancer 1964; 17: 535–8.

Low-risk SCCs have a high cure rate when treated with excision with standard surgical excision, ED&C, and cryosurgery.

Controversies in skin surgery: electrodesiccation and curettage versus excision for low-risk, small, well-differentiated squamous cell carcinomas

Reschly MJ, Shenefelt PD. J Drugs Dermatol 2010; 9: 773–6.

Two retrospective studies. One was a small controlled study in a Veterans Administration teaching hospital dermatology clinic that compared cure rates of low-risk SCCs at 1 year by curettage and electrodesiccation to those of surgical excision. A second study examined the cure rate of low-risk SCCs treated by curettage and electrodesiccation alone in a private practice. The first study found no significant difference in cure rates between curettage and electrodesiccation (14 of 14 cases successfully treated) and excision (15 of 16 successfully treated and 1 recurrence). The second study found the curettage and electrodesiccation cure rate (106 of 106 successfully treated) to be significantly greater than an arbitrary cure rate of 95%.

Prospective trial of curettage and cryosurgery in the management of non-facial, superficial, and minimally invasive basal and squamous cell carcinoma

Peikert JM. Int J Dermatol 2011; 50: 1135–8.

Sixty-nine patients with 100 nonfacial tumors, ≤ 2 cm in diameter, consisting of superficial BCC, superficial nodular BCC with papillary dermal invasion, SCC in situ, and SCC with papillary dermal invasion, were prospectively treated with curettage and cryotherapy and subsequently evaluated at 1- and 5-year intervals. No tumor recurred after 1 year of follow-up, and one recurrence occurred within the 5-year interval, for a 99% recurrence-free end point.

It is important to emphasize that because the more aggressive, high-risk tumors are treated with MMS, the reported recurrence rates for some non-Mohs modalities, particularly for electrodesiccation and curettage, reserved for low-risk skin cancers, are likely to be underestimated compared with those for MMS.

Statistical analysis in cryosurgery of skin cancer

Graham GF, Clark LC. Clin Dermatol 1990; 8: 101–7.

Cryosurgery should be considered only for small (<1 cm), low-risk SCC and SCC in situ because of the low cure rates achieved when the technique is used for higher-risk tumors. Permanent pigment loss, atrophy, and hypertrophic scarring are common.

Office-based radiation therapy for cutaneous carcinoma: evaluation of 710 treatments

Hernandez-Machin B, Borrego L, Gil-Garcia M, Hernandez BH. Int J Dermatol 2007; 46: 453–9.

A retrospective study of 604 BCCs and 106 SCCs irradiated between 1971 and 1996 revealed cure rates for SCC of 92.7% at 5 years and 78.6% at 15 years, suggesting that radiation therapy is an effective first option in many cases.

Management of nonmelanoma skin cancer in 2007

Neville JA, Welch E, Leffell DJ. Nat Clin Pract Oncol 2007; 4: 462–9.

Radiation therapy as a primary treatment modality for SCC is best reserved for those situations in which surgical risk is not acceptable. Radiation therapy is generally reserved for patients over 50 years of age because of the potential long-term sequelae.

The use of brachytherapy in the treatment of nonmelanoma skin cancer: a review

Alam M, Nanda S, Mittal BB, Kim NA, Yoo S. J Am Acad Dermatol 2011; 65: 377–88.

Recurrence after treatment of nonmelanoma skin cancer: a prospective cohort study

Chren MM, Torres JS, Stuart SE, Bertenthal D, Labrador RJ, Boscardin WJ. Arch Dermatol 2011; 147: 540–6.

This was a prospective, long-term study (median 6.6 years after treatment) to determine tumor recurrence rates after treatment. Consecutive samples were taken from all 495 patients with 616 primary nonmelanoma skin cancers diagnosed in 1999 and 2000. A total of 127 tumors were treated with curettage and electrodesiccation (20.9%), 309 with excision (50.8%), and 172 with Mohs surgery (28.3%). Over the course of the study, 21 tumors recurred (3.5%): 2 (2 BCC) after curettage and electrodesiccation (1.6%), 13 (9 BCC, 4 SCC)

after excision (4.2%), and 6 (4 BCC, 2 SCC) after Mohs surgery (3.5%). Recurrent tumors were detected earliest after curettage and electrodesiccation (1.5 years) and latest after Mohs surgery (6.0 years). Median time to detection of recurrence after excision was 3.8 years.

High-risk cutaneous squamous cell carcinoma without palpable lymphadenopathy: is there a therapeutic role for elective neck dissection?

Marinez JC, Cook JL. Dermatol Surg 2007; 33: 410–20.

A literature review suggested that patients with cutaneous SCC who underwent elective node dissection had no proven survival benefit over those who are initially staged as node negative and undergo therapeutic neck dissection after the development of apparent regional disease.

Second-Line Therapies

• Topical imiquimod	A
• Topical 5-fluorouracil	B
• Photodynamic therapy	B
• Intralesional interferon- α	B
• Intralesional methotrexate	D
• Intralesional 5-fluorouracil	B
• Electrochemotherapy with bleomycin	B
• Intralesional bleomycin	E

Imiquimod 5% cream in the treatment of Bowen's disease and invasive squamous cell carcinoma

Peris K, Micantonio T, Fagnoli MC, Lozzi GP, Chimenti S. J Am Acad

Dermatol 2006; 55: 324–7.

This open-label clinical trial used imiquimod 5% cream five times a week for up to 16 weeks to treat seven invasive SCC lesions on 10 patients. Five sites (71.4%) showed complete clinicopathologic regression and two (28.6%) partial regression at 16 weeks. There were no recurrences at a mean of 31 months, follow-up.

Topical imiquimod or fluorouracil therapy for basal and squamous cell carcinoma: a systematic review

Love WE, Bernhard JD, Bordeaux JS. Arch Dermatol 2009; 145: 1431–8.

Clearance rates varied by drug regimen, and most of the studies lacked long-term follow-up. Imiquimod produced clearance rates of 73% to 88% for SCC in situ and 71% for invasive SCC. FU use produced 27% to 85% clearance for SCC in situ. Up to 100% and 97% of patients applying imiquimod and FU, respectively, experienced at least one adverse event such as erythema, pruritus, and pain.

Methyl-aminolevulinate photodynamic therapy for the treatment of actinic keratoses and non-melanoma skin cancers: a retrospective analysis of response in 462 patients

Fai D, Arpaia N, Romano I, Vestita M, Cassano N, Vena GA. G Ital Dermatol Venereol 2009; 144: 281–5.

This case series included 210 patients with actinic keratosis, 228 subjects with 348 BCCs, 17 patients with Bowen disease, and 7 patients with SCC. Bowen disease is very responsive to methyl-aminolevulinate photodynamic therapy, unlike microinvasive or invasive SCC.

Intralesional interferon alpha-2b in the treatment of basal cell carcinoma and squamous cell carcinoma: revisited

Kim KH, Yavel RM, Gross VL, Brody N. Dermatol Surg 2004; 30: 116–20.

Five BCCs and three SCCs were treated with a series of 1.0 to 2.5 million units IFN- α_{2b} intralesional injections administered over a 3- to 5-week period, for a total dosage of 9 to 30 million units. The mean follow-up period after treatment was 33 months. There were no clinically evident recurrences.

Intralesional methotrexate treatment for keratoacanthoma

tumors: a retrospective study and review of the literature

Annest NM, VanBeek MJ, Arpey CJ, Whitaker DC. J Am Acad Dermatol 2007; 56: 989–93.

Cases of keratoacanthoma (KA) treated with intralesional methotrexate (MTX) were identified from the authors' institution ($n = 18$) and literature search ($n = 20$). Intralesional MTX achieved resolution in 92%, requiring an average of 2.1 injections an average of 18 days apart. Adverse events were rare, with two reports of pancytopenia in patients with chronic renal failure. The authors concluded that intralesional MTX is a useful nonsurgical therapy for KA, that histologic diagnosis before initiation of treatment is preferred, and a complete blood cell count at baseline and during treatment should be considered.

Intralesional chemotherapy for nonmelanoma skin cancer: a practical review

Kirby JS, Miller CJ. J Am Acad Dermatol 2010; 63: 689–702.

A review article with guidelines for the treatment of SCC, KA, and BCC with the most widely available intralesional agents (methotrexate, 5-FU, bleomycin, and IFN).

Intralesional agents in the management of cutaneous malignancy: a review

Good LM, Miller MD, High WA. J Am Acad Dermatol 2011; 64: 413–22.

A comprehensive review on intralesional agents and their role in cutaneous neoplasms.

Third-Line Therapies

• Systemic retinoids	B
• Chemotherapy	B
• Amputation	D

Acitretin suppression of squamous cell carcinoma: case report and literature review

Lebwohl M, Tannis C, Carrasco D. J Dermatol Treat 2003; 14: 3–6.

A patient with psoriasis who developed multiple SCCs after being previously treated with psoralen and ultraviolet A for 4.5 years was started on 25 mg daily of acitretin, which resulted in a reduction in the number of SCCs. The mechanism of action is reviewed.

Oral retinoid use reduces cutaneous squamous cell carcinoma risk in patients with psoriasis treated with psoralen-UVA: a nested cohort study

Nijsten TEC, Stern RS. J Am Acad Dermatol 2003; 49: 644–50.

A cohort of 135 patients participating in the PUVA follow-up study with at least 1 year of substantial retinoid use was identified. Each patient's tumor incidence during retinoid therapy was compared with the incidence of SCC development in periods of no use. Overall, a 30% reduction in SCC incidence was noted when patients were on oral retinoid therapy. Retinoids (isotretinoin, acitretin) may play a role in the treatment of patients with SCC not amenable to surgical extirpation due to advanced stage of disease or large number of lesions, with an overall response rate of about 70%.

Systemic retinoids for chemoprevention of non-melanoma skin cancer in high-risk patients

Marquez C, Bair SM, Smithberger E, Cherpelis BS, Glass LF. J Drugs Dermatol 2010; 9: 753–58.

A review of the literature on susceptible individuals, such as organ transplant recipients and those with xeroderma pigmentosum.

Update on the management of high-risk squamous cell carcinoma

LeBoeuf NR, Schmults CD. *Semin Cutan Med Surg* 2011; 30: 26–34.

Cisplatin alone or in combination with 5-FU, methotrexate, bleomycin, or doxorubicin. Capecitabine is an oral prodrug of 5-FU that is metabolized to 5-FU within tumor cells and has fewer adverse effects than systemically administered 5-FU. EGFR inhibitors, including cetuximab and gefitinib, have been used off-label to treat metastatic SCC because of the overexpression of EGFR in some tumors.

Squamous cell carcinoma arising in osteomyelitis and chronic wounds. Treatment with Mohs micrographic surgery vs. amputation

Kirsner RS, Spencer J, Falanga V, Garland LE, Kerdel FA. *Dermatol Surg* 1996; 22: 1015–8.

Patients with extensive local or metastatic SCC of the leg involving bone may require amputation if MMS would render the remaining limb unstable.

Staphylococcal scalded skin syndrome

Dimitra Koch, and Saleem M. Taibjee

Staphylococcal scalded skin syndrome (SSSS) is a highly contagious, blistering condition triggered by exfoliative, toxin-producing *Staphylococcus aureus*, most commonly affecting neonates and children under the age of 6 years. It rarely presents in adults, usually in association with renal failure, immunocompromis, and

possibly nonsteroidal antiinflammatory drugs (NSAIDs). SSSS can develop after viral illnesses such as respiratory tract infections and varicella and after skin-penetrating procedures such as heel prick and vitamin K injections in neonates, intraarticular injections, and peritoneal dialysis.

The estimated incidence in Western countries ranges from 0.56 to 2.51 cases/year/million inhabitants with a reported seasonal peak in summer/autumn. In healthy infants mortality is uncommon, with reported rates up to 3%, contrasting with up to 50% to 60% in adults with comorbidity. Death occurs due to complications such as pneumonia, hypovolemia, electrolyte imbalance, and sepsis.

SSSS is caused by hematogenous spread of exfoliative toxin (ET), mainly ET-A and/or B, produced by *S. aureus*, including methicillin-sensitive (MSSA), methicillin-resistant (MRSA), and multidrug resistant strains. Approximately 5% of all *S. aureus* produce ET. ET-producing MRSA strains appear more prevalent in Japan. ETs are serine proteases specifically cleaving desmosomal protein desmoglein-1, disrupting keratinocyte adhesion in the superficial epidermis. Increased susceptibility may reflect impaired renal clearance of ET in neonates and adults with renal failure or low titers of ET-specific antibodies in immunocompromised individuals.

Clinical features include a prodrome of malaise, irritability, and fever. Skin manifestations develop within 24 to 48 hours. Tender erythema is followed by superficial, flaccid blistering, most pronounced in flexural and periorificial areas, sparing mucosal surfaces, and ranging from localized blisters to widespread exfoliation. This leads to impaired thermoregulation and fluid balance and susceptibility to sepsis and secondary infection. Nikolsky sign is positive. With successful treatment SSSS resolves over 10 to 14 days. Bullae rupture to leave denuded skin, followed by reepithelialization without scarring.

The causative organism cannot usually be cultured from affected skin, because this is a circulating toxin-mediated process. The infection may be acquired by skin-to-skin contact from another individual with either a symptomatic infection or who is an asymptomatic carrier. It may be possible to culture ET-producing *S. aureus* from extracutaneous sites, most commonly the nasopharynx, but also the rectum, conjunctiva, urinary tract, umbilicus, and blood. Polymerase chain reaction (PCR) or random amplified polymorphic DNA analysis may identify the toxin-encoding genes. Histology of

affected skin typically shows a superficial subcorneal blister; absence of epidermal necrosis and minimal inflammation. A frozen section of blister roof can confirm the superficial level of cleavage, facilitating a more rapid diagnosis.

The main differential diagnosis is the Stevens–Johnson syndrome–toxic epidermal necrolysis spectrum, in which distinguishing features include targetoid skin lesions, mucosal involvement, and subepidermal level of blistering with full-thickness epidermal necrosis. Additional differential diagnoses in infants include hereditary conditions such as epidermolysis bullosa, epidermolytic ichthyosis, and bullous mastocytosis.

Management Strategy

Treatment includes antibiotic therapy in combination with supportive measures addressing electrolyte and fluid balance, temperature regulation, nutrition, analgesia, and skin care. Bland *emollients* such as 50:50 white soft paraffin/liquid paraffin should be applied regularly to reduce friction and insensible fluid losses. Nonadherent dressings are used to cover denuded areas, with avoidance of adhesive tapes directly on skin. *Systemic β -lactamase-resistant antibiotics* are necessary to eradicate the causative *S. aureus* strain. Patients with extensive SSSS require intravenous antibiotics and in-hospital care provided by a multidisciplinary team experienced in delivering optimal skin care (e.g., on a burns unit). In view of the growing emergence of resistant ET-producing *S. aureus* strains, in particular MRSA and fusidic acid-resistant strains, antibiotic choice should be guided by local protocols/microbiology advice.

SSSS outbreaks on maternity and neonatal units are reported. Strict infection control measures are advisable, including patient isolation, barrier nursing, and scrupulous handwashing. Screening programs may identify *S. aureus* carriers among contacts, including health care workers. Colonized individuals require treatment with topical antiseptics (e.g., *chlorhexidine*) with nasal carriage eradicated by topical antibiotics such as *mupirocin*.

Nosocomial staphylococcal scalded skin syndrome caused by intraarticular injection

Emberger M, Koller J, Laimer M, Hell M, Oender K, Trost A, et al. J

Eur Acad Dermatol Venereol 2011; 25: 227–31.

Nosocomial outbreak of SSSS in three patients on NSAIDs who received intraarticular injections by an orthopedic surgeon with confirmed ET-producing *S. aureus* nasal colonization.

Nosocomial outbreak of staphylococcal scalded skin syndrome in neonates: epidemiologic investigation and control

El Helali N, Carbonne A, Naas T, Kerneis S, Fresco O, Giovangrandi YP, et al. J Hosp Infect 2005; 61: 130–8.

SSSS outbreak affecting 13 neonates in a maternity unit; temporary removal from duty of a nurse with chronic hand dermatitis confirmed as a carrier of the causative ET-producing *S. aureus*. Infection control measures (patient isolation, barrier-nursing, chlorhexidine handwashing, treatment of carriers with nasal mupirocin, and chlorhexidine showers) controlled the outbreak. All affected neonates were successfully treated with oxacillin.

Health care workers are an important potential source in outbreaks.

Specific Investigations

- Nose, throat, conjunctival, umbilical, rectal, and skin swabs for bacterial culture and sensitivities
- Culture from suspected site of primary infection
- Polymerase chain reaction (PCR) for rapid detection and characterization of SSSS-associated *S. aureus*
- Blood cultures
- Full blood count
- Serum urea, creatinine, and electrolytes
- Skin biopsy or frozen section of blister roof
- Dermoscopy
- Screening contacts for *S. aureus* carriage

Isolating *Staphylococcus aureus* from children with suspected staphylococcal scalded skin syndrome is not clinically useful

Ladhani S, Robbie S, Chapple DS, Joannou CL, Evans RW. Pediatr Infect Dis J 2003; 22: 284–6.

Polymerase chain reaction for *ETA* and *ETB* genes and Western blotting confirmed ET-producing strains in only 17 of 54 (31%) isolates over a 4-year study period.

Failure to isolate ET-producing S. aureus from affected skin does not exclude the diagnosis of SSSS.

Staphylococcal scalded skin syndrome in an extremely low-birth-weight neonate: molecular characterization and rapid detection by multiplex and real-time PCR of methicillin-resistant *Staphylococcus aureus*

Shi D, Ishii S, Sato T, Yamazaki H, Matsunaga M, Higuchi W, et al. *Pediatr Int* 2011; 53: 211–7.

Multiplex and PCR assays were developed to target five virulence genes (*ETA*, *ETB*, *ETD*, *PVL*, *CNA*), aiming at rapid detection of SSSS-associated MRSA.

Adult case of staphylococcal scalded skin syndrome differentiated from toxic epidermal necrolysis with the aid of dermoscopy

Miyashita K, Ogawa K, Iioka H, Miyagawa F, Okazaki A, Kobayashi N, et al. *J Dermatol* 2016; 43: 842–3.

Dermoscopy as a diagnostic tool was utilized to demonstrate superficial level of cleavage at a fresh exfoliation site; subcorneal detachment was subsequently confirmed histologically.

Nosocomial outbreak of staphylococcal scalded skin syndrome in neonates in England, December 2012 to March 2013

Paranthaman K, Bentley A, Milne LM, Kearns A, Loader S, Thomas A, et al. *Euro Surveill* 2014; 19: 1–7.

A health care worker with chronic hand dermatitis was identified as the source of the outbreak after mass screening involving multisite swabbing and pooled, enrichment culture.

First-Line Therapy

• β -Lactamase-resistant penicillins (e.g., flucloxacillin, oxacillin)	D
--	----------

Epidemiological data of staphylococcal scalded skin syndrome in France from 1997 to 2007 and microbiological characteristics of *Staphylococcus aureus* associated strains

Lamand V, Dauwalder O, Tristan A, Casalegno JS, Meugnier H, Bes M, et al. Clin Microbiol Infect 2012; 18: E514–21.

This retrospective study reports 349 cases of SSSS, including bullous impetigo and generalized exfoliative exanthema. All cases were MSSA-induced except one MRSA-associated case.

Antibiotic sensitivity and resistance patterns in pediatric staphylococcal scalded skin syndrome

Braunstein I, Wanat KA, Abuabara K, McGowan KL, Yan AC, Treat JR. Pediatr Dermatol 2014; 31: 305–8.

This retrospective study of 21 culture-confirmed SSSS cases at the Children's Hospital of Philadelphia between 2005 and 2011 reports 86% oxacillin-susceptible and 52% clindamycin-resistant SSSS cases.

Mild staphylococcal scalded skin syndrome: an underdiagnosed clinical disorder

Hubiche T, Bes M, Roudiere L, Langlaude F, Etienne J, Del Giudice P. Br J Dermatol 2012; 166: 213–5.

Five children, age range 7 to 48 months, with a mild form of SSSS devoid of systemic symptoms, were successfully treated with intravenous oxacillin (100 mg/kg daily); one patient had additional gentamicin.

Second-Line Therapy

• Glycopeptide antibiotic (e.g., vancomycin)	E
--	----------

Emergence of *Staphylococcus aureus* carrying multiple drug resistance genes on a plasmid encoding exfoliative toxin B

Hisatsune J, Hirakawa H, Yamaguchi T, Fudaba Y, Oshima K, Hattori M et al. Antimicrob Agents Chemother 2013; 57: 6131–40.

ETB-producing *S. aureus*, including MRSA strains, causing impetigo/SSSS is more prevalent in Japan than in Western countries. Reports indicate a significant increase in strains resistant to beta-lactams, erythromycin, and gentamicin in Japan.

Staphylococcal scalded skin syndrome in the course of lupus

nephritis

Rydzewska-Rosolowska A, Brzosko S, Borawski J, Mysliwiec M. Nephrology 2008; 13: 265–6.

An adult with systemic lupus erythematosus, antiphospholipid syndrome, and chronic renal failure receiving pulsed cyclophosphamide and prednisolone developed SSSS due to MRSA. She recovered with intravenous vancomycin therapy (750 mg every 48 hours).

A reduced vancomycin dosage is required in renal failure.

Staphylococcal scalded skin syndrome in an adult due to methicillin-resistant *Staphylococcus aureus*

Ito Y, Yoh MF, Toda K, Shimazaki M, Nakamura T, Morita E. J Infect Chemother 2002; 8: 256–61.

An adult with diabetes mellitus and metastatic renal cell carcinoma who developed cholecystitis and SSSS due to ET-producing MRSA was successfully treated with a combination of intravenous vancomycin and teicoplanin and percutaneous transhepatic gallbladder drainage.

Third-Line Therapies

• Cephalosporins	D
• Aminoglycosides	D
• Pooled human immunoglobulin	E
• Fresh-frozen plasma	E
• Skin substitute dressings	E
• Plasma exchange	E

Staphylococcal scalded skin syndrome in neonates: an 8-year

retrospective study in a single institution

Li MY, Wei GH, Qiu L. *Pediatr Dermatol* 2014; 31: 43–7.

Thirty-nine neonates were successfully treated at a southwest Chinese neonatal unit between 2004 and 2012 for clinically diagnosed SSSS. Four received a cephalosporin (50–100 mg/kg/day), 2 a β -lactam (50–100 mg/kg/day), 24 both cephalosporin and β -lactam (50–100 mg/kg/day), 5 vancomycin (20 mg/kg/day), and 4 gamma globulin in addition to cephalosporin and β -lactam. Median days of hospitalization were longer for immunoglobulin therapy.

Staphylococcal scalded skin syndrome as a harbinger of late-onset staphylococcal septicaemia in a premature infant of very low birth weight

Hütten M, Heimann K, Baron JM, Wenzl TG, Merk H, Ott H. *Acta Derm Venereol* 2008; 88: 416–7.

A preterm (29 weeks of gestation), extremely low-birth-weight (985 g) male infant developed SSSS (ETA- and B-producing MSSA strain) at 37 days with systemic symptoms and was successfully treated with intravenous cefuroxime (100 mg/kg body weight) in an incubator with high air humidity, minimal handling, and 100% maintenance fluid plus the Parkland correction for a 15% epidermal loss.

Neonatal staphylococcal scalded skin syndrome: clinical and outbreak containment review

Neylon O, O'Connell NH, Slevin B, Powell J, Monahan R, Boyle L, et al. *Eur J Pediatr* 2010; 169: 1503–9.

Five neonates were successfully treated for MSSA ET-A-mediated SSSS with flucloxacillin and gentamicin given intravenously for a mean of 5.8 days followed by a mean of 3.8 days, oral flucloxacillin.

Adult staphylococcus scalded skin syndrome in a peritoneal dialysis patient

Suzuki R, Iwasaki S, Ito Y, Hasegawa T, Yamamoto T, Ideura T, et al. *Clin Exp Nephrol* 2003; 7: 77–80.

An adult undergoing peritoneal dialysis developed acute peritonitis initially treated with intraperitoneal and intravenous vancomycin (0.5 g/day each, 1 g/day total). He subsequently developed SSSS with septic shock and was successfully treated with intravenous amikacin (100 mg/day) for 1 day followed by cefoperazone with sulbactam.

Staphylococcal scalded skin syndrome in an extremely premature neonate: a case report with a brief review of the literature

Kapoor V, Travadi J, Braye S. J Pediatr Child Health 2008; 44: 374–6.

A premature neonate with SSSS was successfully treated with intravenous flucloxacillin and a single dose of intravenous immunoglobulin 1 g/kg in view of transient low IgG levels.

Severe staphylococcal scalded skin syndrome in children

Blyth M, Estela C, Young ER. Burns 2008; 34: 98–103.

Four children with severe SSSS were successfully treated with a regimen including intravenous penicillinase-resistant penicillin and fresh-frozen plasma, postulated to possess antitoxin properties.

An innovative local treatment for staphylococcal scalded skin syndrome

Mueller E, Haim M, Petnehazy T, Acham-Roschitz B, Trop M. Eur J Clin Microbiol Infect Dis 2010; 29: 893–7.

The benefits of a synthetic copolymer wound dressing (Suprathel, based on DL-lactic acid) are illustrated in a 14-month-old boy with whole-body skin denudation secondary to severe SSSS. The dressing reportedly relieves pain, prevents heat loss and secondary infection, and accelerates wound healing. It is transparent, allowing wound inspection without removal of the dressing, and is cost effective.

Use of skin substitute dressings in the treatment of staphylococcal scalded skin syndrome in neonates and young infants

Baartmans MGA, Docter J, den Hollander JC, Kroon AA, Oranje AP. Neonatology 2011; 100: 9–13.

The use of skin substitutes such as Omiderm, a water vapor-permeable polyurethane membrane, and Suprathel as valuable adjuvant treatments in severe SSSS is described in seven infants.

Optimal skin care with supportive topical treatments provided by an experienced multidisciplinary team is essential (e.g., on a burns unit).

Adult staphylococcal scalded skin syndrome successfully treated with plasma exchange

Kato T, Fujimoto N, Nakanishi G, Tsujita Y, Matsumura K, Eguchi Y, et al. Acta Derm Venereol 2015; 95: 612–3.

A 68-year-old-man with infective endocarditis and MRSA sepsis was initially treated with intravenous immunoglobulin, methylprednisolone, and daptomycin for presumed toxic epidermal necrolysis. The skin desquamation improved after plasma exchange therapy. SSSS was diagnosed retrospectively upon skin histology and bacterial culture results.

Steatocystoma multiplex

Ian Coulson

Although probably genetically heterogeneous, steatocystoma multiplex often demonstrates an autosomal-dominant pattern of inheritance. Some pedigrees have demonstrable keratin 17 abnormalities. It is characterized by the development in adolescence

or early adulthood of cysts on the trunk and proximal limbs, or in some patients on the face and scalp. These are true sebaceous cysts: they contain sebum, and sebaceous gland lobules are present in the their walls. Overlap with eruptive vellus hair cysts and association with pachyonychia congenita type II have been reported. Some cases may be associated with persistent primary dentition.

Management Strategy

The cysts persist indefinitely. Although usually a minor cosmetic problem, they can be highly disfiguring. Paradoxically, those patients who would benefit the most from treatment are sometimes regarded as being unsuitable for surgery because they have too many cysts to excise. The *surgical* technique described later is quick and so can be used on large numbers of lesions in one session. It produces good cosmetic results.

Lesions can become inflamed due to rupture of the cyst wall, with leakage of the contents into the dermis, or because of secondary bacterial infection. Suppuration and scarring may follow. The clinical picture then resembles cystic acne and is called *steatocystoma multiplex suppurativum*. Oral *isotretinoin* is an effective treatment for inflammatory lesions but not for noninflamed cysts. This suggests it operates by a direct antiinflammatory effect rather than by reducing the sebum excretion rate. Alternatively, inflamed cysts can be treated with *incision and drainage*, *intralesional triamcinolone*, *tetracycline* 1 g/day, or *minocycline* 100 to 200 mg/day.

Topical treatment is largely ineffective because it does not penetrate to reach the cyst wall.

Specific Investigations

- Skin biopsy if diagnosis is in doubt
- Keratin gene testing

A novel mutation (p.Arg94Gly) of keratin 17 in a Chinese family with *steatocystoma multiplex*

Zang D, Zhou C, He M, Ma X, Zhang J. Eur J Dermatol 2011; 21: 142–4.

Steatocystoma multiplex, oligodontia and partial persistent primary dentition associated with a novel keratin 17 mutation

Gass JK, Wilson NJ, Smith FJ, Lane EB, McLean WH, Rytina E, et al. Br J Dermatol 2009; 161: 1396–8.

First-Line Therapies

Lesions not inflamed

• Surgical incision and extraction of cyst wall	D
---	----------

Inflamed lesions

• Isotretinoin	D
• Antibiotics	E
• Incision and drainage	E

Steatocystoma multiplex suppurativum: treatment with isotretinoin

Schwartz JL, Goldsmith LA. Cutis 1984; 34: 149–53.

The treatment of steatocystoma multiplex suppurativum with isotretinoin

Statham BN, Cunliffe WJ. Br J Dermatol 1984; 111: 246.

Isotretinoin in the treatment of steatocystoma multiplex: a possible adverse reaction

Rosen BL, Broadkin RH. Cutis 1986; 115: 115–20.

Steatocystoma multiplex treated with isotretinoin: a delayed response

Mortiz DL, Silverman RA. *Cutis* 1988; 42: 437–9.

Treatment of steatocystoma multiplex and pseudofolliculitis barbae with isotretinoin

Friedman SJ. *Cutis* 1987; 39: 506–7.

These five papers report a total of seven patients treated with oral isotretinoin at a dose of approximately 1 mg/kg/day for about 20 weeks. Inflammation of cysts was greatly reduced. Noninflammatory lesions were unaffected and in one patient appeared to increase in size and number. One successfully treated patient relapsed 10 weeks after ceasing therapy, but other patients did not relapse during a follow-up period of up to 8 months.

Successful treatment of steatocystoma multiplex by simple surgery

Keefe M, Leppard BJ, Royle G. *Br J Dermatol* 1992; 127: 41–4.

Five generations with steatocystoma multiplex congenita: a treatment regimen

Pamoukian VN, Westreich M. *Plast Reconstruct Surg* 1997; 99: 1142–6.

Surgical pearl: mini-incisions for the extraction of steatocystoma multiplex

Schmook T, Burg G, Hafner J. *J Am Acad Dermatol* 2001; 44: 1041–2.

A simple surgical technique for the treatment of steatocystoma multiplex

Kaya TI, Ikizoglu G, Kokturk A, Tursen U. *Int J Dermatol* 2001; 40: 785–8.

Suggestion for the treatment of steatocystoma multiplex located exclusively on the face

Duzova AN, Senturk GB. *Int J Dermatol* 2004; 43: 60–2.

The vein hook successfully used for eradication of steatocystoma multiplex

Lee SJ, Choe YS, Park BC, Lee WJ, Kim DW. *Dermatol Surg* 2007; 33: 82–4.

Perforation and extirpation of steatocystoma multiplex

Madan V, August PJ. Int J Dermatol 2009; 48: 329–30.

These seven reports describe variants of a simple surgical technique for noninflamed cysts. Local, regional, general, or no anesthesia is used, depending on the exact technique and the number of cysts being treated. In most cases a 1- to 10-mm incision is made with a surgical blade, and the contents of the cyst are expressed; fine artery forceps are then passed through the opening to grasp the base of the cyst, which is pulled out. The incisions heal by secondary intention. Good cosmetic results and a very low recurrence rate are reported.

Excision of cysts and aspiration have also been described.

Second-Line Therapies

• CO ₂ laser therapy	E
• Combination laser therapy	E

CO₂ laser therapy for steatocystoma multiplex

Krahenbuhl A, Eichmann A, Pfaltz M. Dermatologica 1991; 183: 294–6.

“Fairly good” results were reported.

1450-nm diode laser in combination with the 1550-nm fractionated erbium-doped fiber laser for the treatment of steatocystoma multiplex: a case report

Moody MN, Landau JM, Goldberg LH, Friedman PM. Dermatol Surg 2012; 38: 1104–6.

A single case report showing substantial clearance of chest and abdominal steatocystoma after two laser treatment sessions using two complementary lasers: a 1450-nm diode laser to target the abnormal sebaceous glands and a 1550-nm fractionated erbium-doped fiber laser to target the dermal cysts.

Carbon dioxide laser perforation and extirpation of steatocystoma multiplex

Bakkour W, Madan V. *Dermatol Surg* 2014; 40: 658–62.

A series of eight patients with multiple lesions treated by CO₂ laser puncturing of the cysts, followed by enucleation of the cyst contents with a Volkmann spoon. This resulted in high patient satisfaction and low recurrence rates, with minimal scarring.

Fractionated ablative carbon dioxide laser treatment of steatocystoma multiplex

Kassira S, Korta DZ, de Feraudy S, Zachary CB. *J Cosmet Laser Ther* 2016; 16: 1–12.

A 51-year-old woman with steatocystoma limited to the face, who after two treatments with a fractionated ablative carbon dioxide laser remained free of cysts for 3 years.

Third-Line Therapy

• Cryotherapy	E
---------------	---

Treatment of lesions of steatocystoma multiplex and other epidermal cysts by cryosurgery

Notowicz A. *J Dermatol Surg Oncol* 1980; 6: 98–9.

Three or 4 days after cryotherapy, the necrotic skin overlying the cyst was removed and the intact cyst expressed through the opening.

233

Stoma care

Calum C. Lyon

Stomas are artificial openings created to maintain proper drainage from internal structures. The most common are colostomies, ileostomies, and urostomies (ileal conduits), formed as either a temporary or a permanent measure. They are ideally produced

electively, having been correctly sited by a stoma nurse specialist, but may be created under emergency conditions. Even with the best of preventative measures dermatologic problems will occur in over 50% of patients at some time. These are mostly irritant reactions to body fluids, particularly in the higher-output stomas (ileostomy and urostomy), but a range of common skin disorders, infections, or any dermatosis exacerbated by trauma or irritation may also be seen ([Table 233.1](#) online).

Management Strategy

Although all irritant reactions share similar histologic features, the clinical appearance depends on the type of stoma and the source of irritation. Ileostomies have a high output containing degradative enzymes and irritant bile acids, so severe dermatitis and erosions may be seen. Irritated colostomies generally have a milder dermatitis, often due to occlusion, but sizeable hypergranulating polyps and acanthomas can occur where there are leaks. Urostomy dermatitis may also be erosive because of the high output and ileal mucus production, predisposing to leaks. Chronic papillomatous dermatitis is a distinct eruption comprising aggregating hyperplastic papulonodules that usually affects leaking urostomies. It responds to appliance modifications and acidification of the urine.

Input from an expert stoma nurse is essential when managing irritant reactions. He or she can advise on the most appropriate appliance so that mechanical trauma to the skin or stoma and exposure of normal skin to effluent can be avoided. Patients anxious to avoid leaks, smells, etc., sometimes wear bags too tightly or change them excessively, frequently resulting in skin damage and irritation. The stoma nurse specialist is trained to identify and resolve such issues.

It is appropriate to treat symptomatic irritant inflammation with antiinflammatory preparations such as *topical corticosteroids*, *tacrolimus*, or *pimecrolimus*. The choice of vehicle is very important, as oily creams, etc., will prevent proper adhesion and cause leaks. Products useful on peristomal skin include a range of foams, lotions, and gels formulated for scalp, ear, or eye disorders, and corticosteroid asthma inhalers ([Table 233.2](#) and online). *Flurandrenolide tape*, an occlusive corticosteroid therapy, is particularly useful because the stoma device can be applied over the tape. Leaks and inflammation

are sometimes inevitable despite appliance changes. It may be necessary to use topical antiinflammatories intermittently, with care taken to avoid steroid atrophy. Hypergranulation can be treated with *silver nitrate*, *cryotherapy*, or *cautery ± shave or curettage*.

Allergic contact dermatitis is rare, as ostomy manufacturers strive to minimize allergens in their products. When it occurs it is mostly due to perfumed deodorizers and excipients in topical products (e.g., biocides in wet wipes). Usage tests are particularly helpful in identifying the offending product, even if patch testing fails to identify the precise allergen. Treatment is as for irritant reactions.

Skin infection is not uncommon in the moist and warm environment under a stoma bag, especially folliculitis in those who shave their abdomens. All rashes should be swabbed for culture and sensitivity, because bacterial infection can present as a nonspecific dermatitis under occlusion, and preexisting rashes can become secondarily infected. Treatment involves careful hygiene and the use of specific antimicrobials.

Preexisting skin diseases that particularly affect stomas are psoriasis, seborrheic dermatitis, cutaneous Crohn disease, pyoderma gangrenosum, lichen sclerosus, and eczema.

Specific Investigations

- Skin biopsy
- Wound culture
- Patch testing and usage test

The spectrum of skin disorders in abdominal stoma patients

Lyon CC, Smith AJ, Griffiths CEM, Beck MH. Br J Dermatol 2000; 143: 1248–60.

This large cohort study documented the many different types of skin disorders that can occur around a stoma. Initial evaluations for patients presenting with inflammation include a bacterial swab because infections are relatively common and easy to treat. Allergic contact hypersensitivity should be suspected in any patient with persistent disease that is unresponsive to treatment. A biopsy should be performed for any peristomal skin disorder with ulceration or a papular component.

This is a comprehensive review discussing the various different

pathologies that can occur with a stoma and how to evaluate them.

Table 233.1

Peristomal skin disorders according to primary source

Source of skin problems	Examples	Effects on skin
Appliance (pouch)	Chronic occlusion (common) Potential allergens or irritants (very rare) in appliances such as adhesives and tackifiers	Damage to skin barrier function resulting in dermatitis
Accessories: (1) pastes (fillers); (2) wet cleansing wipes; (3) deodorizing sprays; (4) skin barrier wipes/lotions; (5) adhesive removers	Irritant contact dermatitis (ICD)	ICD, e.g., alcohol in pastes and wipes, karaya (powder and pastes)
	Allergic contact dermatitis (ACD)	ACD, especially fragrances or preservatives
Stoma effluent where there are leaks	Urine, especially if infection is present Stool, particularly where the consistency is more liquid or volume produced is high. More proximal stomas will produce larger volume with greater enzymic content. <i>Measures to thicken the stool should be considered, including diet advice and antimotility drugs, e.g., loperamide.</i>	Irritant reactions, including dermatitis, granulomas, and chronic papillomatous dermatitis
Stoma	Type: loop stomas are associated with more skin complications	As earlier
	Structural integrity: short, buried, or prolapsed stomas are more prone to leaks	
Skin	Genetic problems (rare, e.g., ichthyotic or bullous disorders) Common acquired disorders such as eczema or psoriasis can present atypically under occlusion. Rarer disorders may be more frequent than expected because of the population affected, e.g., pemphigoid in older patients with colostomies and pyoderma gangrenosum in young adults with ileostomies for inflammatory bowel disease.	Any inflammatory or scaly skin disease may impair bag adhesion and cause leaks that precipitate irritant reactions that in turn can worsen the primary skin problem
Infections	Dermatophyte, <i>Candida</i> , and viral infections present typically. Bacterial infections may mimic or secondarily affect common disorders such as eczema	Eroded dermatitis, folliculitis, and occasionally ulceration

Table 233.2

Available topical corticosteroid preparations for inflammatory peristomal disorders

Preparation	Trade name	Other ingredients
Betamethasone valerate 0.1% scalp lotion ⁽¹⁾	Betnovate	Carbomer, sodium hydroxide, and water
Betamethasone dipropionate 0.05% scalp lotion	Diprosone	Carbomer, sodium hydroxide, and water
Clobetasol propionate 0.05% scalp lotion	Dermovate	Carbomer, sodium hydroxide, and water
Clobetasol propionate 0.05% spray scalp foam	Clarelux	Cetyl alcohol, propylene glycol, stearyl alcohol
Fluocinolone 0.025% scalp gel	Synalar	Benzoates and propylene glycol
Betamethasone and calcipotriol scalp gel to treat psoriasis	Dovobet gel	Paraffin, liquid, polyoxypropylene-15 stearyl ether, castor oil, butylhydroxytoluene (E321)
Beclomethasone dipropionate 200 mcg/metered dose asthma inhaler ⁽²⁾	Clenil Modulite	None
Crushed prednisone tablets to treat pyoderma gangrenosum ⁽³⁾		
Fludrocortide 4 mcg/cm ² tape	Haelan	None

The incidence of stoma and peristomal complications during the first 3 months after ostomy creation

Salvadalea GD. J Wound Ostomy Continence Nurs 2013; 40: 400–6.

A prospective case series showing irritation and infection to be the most common problems.

A prospective audit of stomas – analysis of risk factors and

complications and their management

Arumugam PJ, Bevan L, Macdonald L, Watkins AJ, Morgan AR, Beynon J, et al. *Colorectal Dis* 2003; 5: 49–52.

Healthy peristomal skin is dependent on good surgical technique, with more problems being associated with short stomas (ileostomies <20 mm and colostomies <5 mm) and after emergency procedures. Body mass index and diabetes are significantly associated with skin problems. Bleeding hypergranulation is more common in colostomies. Careful postoperative stoma nurse follow-up helps prevent skin problems.

The relevance of patch testing in peristomal dermatitis

Al-Niaimi F, Beck M, Almaani N, Samarasinghe V, Williams J, Lyon C. *Br J Dermatol* 2012; 167: 103–9.

A subset of 149 patients from a cohort of 850 were patch-tested to a comprehensive series of potential allergens. Only seven of these had reactions of current relevance, and most of these were to common fragrances and preservatives in stoma accessories rather than pouching systems.

First-Line Therapies

• Change appliance	D
• Absorbent powders	D
• Antibiotics	D
• Topical corticosteroids	B

Dermatologic considerations of stoma care

Rothstein MS. *J Am Acad Dermatol* 1986; 15: 411–32.

Ill-fitting devices can cause stoma and skin irritation. The chemical

irritation caused from the stomal effluent, mechanical irritation, and contact dermatitis can all be alleviated by replacing the stoma device at the earliest sign of irritation. Additionally, careful drying of the skin after washing and the use of absorbent powders will alleviate irritation caused by intertrigo and ill-fitting devices.

Peristomal dermatoses: a novel indication for topical steroid lotions

Lyon CC, Smith AJ, Griffiths CEM, Beck MH. J Am Acad Dermatol 2000; 43: 679–82.

This large clinical study demonstrated the benefits of treating inflammatory peristomal skin diseases with topical corticosteroids formulated in an aqueous alcohol lotion. This formulation was found advantageous because it did not interfere with adhesion of the ostomy bag to the skin.

Topical therapy for peristomal pyoderma gangrenosum (PPG)

Nybaek H, Olsen AG, Karslmark T, Jemec G. J Cutan Med Surg 2004; 8: 220–3.

Most cases of PPG respond to topical therapy, usually corticosteroids.

Second-Line Therapies

• Sucralfate	C
• Tacrolimus ointment or pimecrolimus cream	E
• Intralesional corticosteroids	C

Topical sucralfate in the management of peristomal skin disease: an open study

Lyon CC, Stapelton M, Smith AJ, Griffiths CE, Beck MH. Clin Exp Dermatol 2000; 25: 584–8.

The authors demonstrated the ability of sucralfate to help treat peristomal erosions. Sucralfate is a basic aluminum salt of sucrose octasulfate that polymerizes in acidic environments providing a

viscous barrier on mucosal surfaces. Sucralfate was effective for erosions and irritation caused by either feces or urine. However, it was ineffective for peristomal pyoderma gangrenosum (PPG).

Peristomal pyoderma gangrenosum

Keltz M, Lebwohl M, Bishop S. J Am Acad Dermatol 1992; 27: 360–4.

A patient with PPG is described who responded well to intralesional corticosteroids.

This article also discusses the difficulties in diagnosing PPG.

Peristomal lichen sclerosis (LS): the role of occlusion and urine exposure?

Al-Niaimi F, Lyon C. Br J Dermatol 2013; 168: 643–6.

Nine of 12 patients required intralesional corticosteroids to achieve complete resolution of active lichen sclerosis.

Topical tacrolimus in the management of peristomal pyoderma gangrenosum

Lyon CC, Stapelton M, Smith AJ, Mendelsohn S, Beck MH, Griffiths CE. J Dermatol Treat 2001; 12: 13–7.

Topical tacrolimus (0.3% in carmellose sodium paste) in conjunction with other treatments was found to rapidly heal pyoderma gangrenosum.

Third-Line Therapies

• Botulinum toxin	C
• Oral dapsone	E
• Ciclosporin	D
• Tumor necrosis factor–blocking drugs	E
• Collagen injections	E
• Lipectomy	E
• Stoma revision surgery	E

Management of peristomal pyoderma gangrenosum

Poritz LS, Lebo MA, Bobb AD, Ardell CM, Koltun WA. J Am Coll Surg 2008; 206: 311–5.

PPG is a difficult and frequently misdiagnosed condition. Dapsone, topical cromolyn sodium, ciclosporin, mycophenolate mofetil, or infliximab can be beneficial in treating PPG. PPG will resolve if the stoma can be closed, but resizing a stoma to treat PPG is not indicated, as it will recur at the new stoma site.

Paraileostomy recontouring by collagen sealant injection: a novel approach to one aspect of ileostomy morbidity. Report of a case

Smith GH, Skipworth RJ, Terrace JD, Helal B, Stewart KJ, Anderson DN. Dis Colon Rectum 2007; 50: 1719–23.

Peristomal dermal deformity such as skin creasing impairs appliance placement. A dermal contour defect was successfully treated with intradermal injections of collagen.

A novel use for botulinum toxin A (BoNT-A) in the management of ileostomy and urostomy leaks

Smith VM, Lyon CC. J Wound Ostomy Continence Nurs 2015; 42: 83–8.

Seven of 10 consecutive patients presenting with actively contractile

stomas, which shortened spasmodically, resulting in leaks, responded to BoNT-A injected into stoma musculature.

Troublesome colostomies and urinary stomas treated with suction assisted lipectomy

Samdal F, Amlamd PF, Bakka A, Aasen AO. Eur J Surg 1995; 161: 361–4.

Synchronous panniculectomy with stomal revision for obese patients with stomal stenosis and retraction

Katkoori D, Samavedi S, Kava B, Soloway MS, Manoharan M. BJU Int 2009; 105: 1586–9.

Suction lipectomy or surgical panniculectomy can correct leakage problems, particularly in morbidly obese patients with retracted stomas and without the need for laparotomy.

There is no ideal topical preparation applicable to stomas that is available “off the shelf.” The table details some corticosteroid preparations that can be used. Lotions containing oils should be avoided, and the patient should be warned that gel preparations containing propylene glycol should be left to dry for 10 minutes before placing their bag. Alcoholic scalp lotions can sting when applied to broken skin and can be applied to the bag directly and left to dry before fitting. Some patients, particularly those with longer stomas, are able to use creams or ointments applied to the peristomal skin for 30 to 60 minutes during which time the patient is inactive and a stoma bag is held in place over the stoma using a waist belt. The greasy medicament can then be cleaned from the skin and a bag applied normally. The potency of steroid is increased under occlusion. Continuous daily treatment should be for no more than 4 weeks and thereafter no more than three times per week to avoid skin atrophy.

Striae

Adam S. Nabatian, and Hooman Khorasani

Striae distensae are extremely common lesions that do not cause medical problems. Early striae (striae rubra) are linear, red-to-violaceous patches or plaques that may be pruritic. Gradually, they become white, atrophic, linear, depressed patches along lines of skin tension. They are considered to be linear dermal scars with epidermal atrophy as evidenced by a finely wrinkled appearance and telangiectasias. Common locations include the breasts and abdomen of pregnant women and the shoulders of body builders. Striae are common in teenagers undergoing their growth spurts and in

overweight individuals. Extensive striae that are deeper and wider, and include facial skin, are seen with long-term systemic corticosteroid use. Striae are likely the result of a combination of factors, including genetics, mechanical stress (e.g., growth spurt, bodybuilding, pregnancy), and hormones (e.g., cortisol, estrogen). Although striae will generally fade and become inconspicuous, patients frequently request cosmetic treatments.

Management Strategy

The goal of treatment is a gradual, incremental improvement. In general, the “older” the lesion (striae alba), the less dramatic and more slowly the treatment response will be. The best results are achieved by combining multiple treatment modalities early in the course of evolution. Currently, no “gold standard” treatment modality has been determined.

Several studies have shown that *topical tretinoin* improves the appearance of striae. Based on these reports, striae rubra respond better to this therapy. Although not formally investigated, it is expected that *other topical retinoids* (e.g., *tazarotene*, *adapalene*) may also provide some improvement.

Nonablative lasers produce improvement by stimulating an increase in dermal collagen and elastin. The *pulsed dye laser* has been most studied. Recent studies suggest that improvement is more common in early striae that are pink to red in color. *Ablative lasers* may be more useful than the nonablative counterparts, but have more significant downtime and an increased risk of complications. *Radiofrequency devices* may work by a similar mechanism of dermal heating. Platelet-rich plasma (PRP) is a new treatment used alone or in combination with other treatment modalities such as fractionated lasers or microneedling with good results. PRP is an autologous concentrate of platelets in a small volume of plasma containing high concentrations of growth factors and cytokines that stimulate the production of collagen and proliferation of fibroblasts and keratinocytes. The *excimer laser*, *intense pulsed light*, and *glycolic acid products* appear to be the most promising treatments for mature striae.

Specific Investigations

- Thorough history and physical examination
- Skin biopsy (not generally necessary)
- Serum adrenocorticotropin levels, 24-hour urine free cortisol level, plasma cortisol levels (if no history of growth spurt, bodybuilding, or pregnancy)

The diagnosis and cause of striae are usually straightforward to elucidate. When the lesions are particularly severe and the cause is unknown, laboratory testing to exclude Cushing syndrome is advised. In Cushing syndrome, striae are characterized by their excessive size, depth, and striking red-to-purple color. Occasionally, striae may be confused with linear focal elastosis, which are striae-like, asymptomatic, slightly palpable, yellow bands commonly found on the lower back of older adults. Histologic evaluation, with specific attention given to the elastic fiber content, will clearly differentiate these two entities.

First-Line Therapy

• Observation

D

It is well known that striae tend to become less conspicuous with time. Thus reassurance may be all that is required for the patient who is not overly concerned about his or her striae.

Adolescent striae

Ammar NM, Roa B, Schwartz RA, Janniger CK. *Cutis* 2000; 65: 69–70.

Striae cutis distensae

Nigam PK. *Int J Dermatol* 1989; 28: 426–7.

Second-Line Therapies

• Ablative fractional photothermolysis 10,600-nm laser	B
• Nonablative fractional photothermolysis 1550-nm laser	B
• Pulsed dye laser (PDL) (585 nm)	B
• Intense pulsed light (IPL)	B
• Topical tretinoin	B

Treatment of striae distensae using an ablative 10,600-nm carbon dioxide fractional laser: a retrospective review of 27 participants

Lee SE, Kim JH, Lee SJ, Lee JE, Kang JM, Kim YK, et al. *Dermatol Surg* 2010; 36: 1683–90.

Twenty-seven women with striae were treated with fractional CO₂ (DeepFX, Lumenis Esthetic, Inc., Santa Clara, CA) at pulse energy of 10 mJ and density of 2 (percentage coverage of 10%). Three months after treatment 2 of the 27 participants (7.4%) had grade 4 clinical improvement, 14 (51.9%) had grade 3 improvement, 9 (33.3%) had grade 2 improvement, and 2 (7.4%) had grade 1 improvement. None of the participants showed worsening.

Treatment of striae distensae with nonablative fractional laser versus ablative CO₂ fractional laser: a randomized controlled trial

Yang YJ, Lee GY. *Ann Dermatol* 2011; 23: 481–9.

Twenty-four patients with varying degrees of atrophic striae alba in the abdomen were enrolled in a randomized, blind, split study. The patients were treated with 1550-nm fractional Er:glass laser (Mosaic, Lutronic Co., Seoul, Korea; pulse energy of 50 mJ, a spot density of 100 spots/cm², using a scan area of 5 mm × 10 mm in a static mode with one pass administered per treatment site without overlapping) and ablative fractional CO₂ laser resurfacing (eCO₂, Lutronic Co., Seoul, Korea; pulse energy of 40–50 mJ, a spot density of 75–100 spots/cm², using a scan area of 8 mm × 8 mm in a static mode). Each half of the abdominal lesion was randomly selected and treated three times at intervals of 4 weeks using the same parameters.

Posttreatment pruritus, redness, and hyperpigmentation were reported side effects for both modalities. Clinical improvements were not found to be statistically significant between treatments, although both showed a significant clinical and histopathologic improvement

over pretreatment sites.

Treatment of striae distensae with fractional photothermolysis

Bak H, Kim BJ, Lee WJ, Bang JS, Lee SY, Choi JH, et al. *Dermatol Surg* 2009; 35: 1215–20.

Twenty-two Asian women were treated with two laser treatments (Fraxel SR1500) separated by 4 weeks at pulse energy 30 mJ, density level of 6, and eight passes. Six of 22 (27%) demonstrated marked improvement in striae, with the other 16 showing mild improvement. Outcomes were better in patients with white rather than red striae.

Efficacy of pulsed dye laser versus intense pulsed light in the treatment of striae distensae

Shokeir H, El Bedewi A, Sayed S, El Khalafawy G. *Dermatol Surg* 2014; 40: 632–40.

Sixteen patients with striae rubra and four with striae alba had treatment with PDL for striae on one side of their bodies and treatment with IPL for striae on the other side for five sessions with a 4-week interval between the sessions. 595-nm PDL (Cynosure, Chelmsford, MA) was used with a spot size of 10 mm, pulse duration of 0.5 milliseconds, energy density of 2.5 J/cm², and pulse rate of 1 Hz. Fluorescence IPL (Medical Bio Care, Gothenburg, Sweden) was used with a wavelength of 565 nm, spot size of 10 × 20 mm, pulse duration of 50 to 70 milliseconds, and energy density of 17.5 J/cm². Striae width was decreased, skin texture was improved, and collagen expression was increased significantly after both PDL and IPL. However, PDL induced the expression of collagen I in a significant manner compared with IPL. Striae rubra gave a superior response with either PDL or IPL compared with striae alba.

Topical tretinoin 0.1% for pregnancy-related abdominal striae: an open-label, multicenter, prospective study

Rangel O, Aries I, García E, Lopez-Padilla S. *Adv Ther* 2001; 18: 181–6.

One week post delivery, 20 patients applied tretinoin cream 0.1% once a day for 3 months to half of the abdomen. Eighty percent noted a marked or moderate improvement. Measured striae decreased by 20% in length and by 23% in width.

Third-Line Therapies

• Excimer laser (308 nm)	C
• Copper bromide laser (577–511 nm)	C
• 1064-nm Nd:YAG laser	C
• Radiofrequency and 585-nm PDL	B
• Radiofrequency device	C
• Needling therapy	B
• Platelet-rich plasma (PRP) and microdermabrasion	B
• 20% glycolic acid/0.05% tretinoin	C
• 20% glycolic acid/10% L-ascorbic acid	C
• 70% glycolic acid lotion	A
• 70% glycolic acid gel/40% trichloroacetic acid chemical peel	D

The 308-nm excimer laser in the darkening of the white lines of striae alba

Ostovari N, Saadat N, Nasiri S, Moravvej H, Toossi P. J Dermatolog Treat 2010; 21: 229–31.

Ten subjects were treated using excimer laser on the white lines of striae, whereas the normal skin near to and between the lines was treated with zinc oxide cream. Some repigmentation was noted, and therapy with excimer laser was described as “weakly effective.” Before and after photographs demonstrated that 80% of patients had poor or moderate results.

Two-year follow-up results of copper bromide laser treatment of striae

Longo L, Postigli MG, Marangoni O, Melato M. J Clin Laser Med Surg 2003; 21: 157–60.

Thirteen of 15 patients experienced improvement in their striae that remained after 1 to 2 years. One third of the patients had total disappearance of selected striae.

Stretch marks: treatment using the 1064-nm Nd:YAG laser

Goldman A, Rossato F, Prati C. *Dermatol Surg* 2008; 34: 686–91.

Twenty patients with striae rubra were treated with the 1064-nm Nd:YAG laser; all considered the results satisfactory, and a majority (55%) found the results to be excellent.

Radiofrequency and 585-nm pulsed dye laser treatment of striae distensae: a report of 37 Asian patients

Suh DH, Chang KY, Son HC, Ryu JH, Lee SJ, Song KY. *Dermatol Surg* 2007; 33: 29–34.

Thirty-seven patients were treated with one session of radiofrequency (Thermage) and three monthly sessions of the 585-nm PDL. A majority of patients (89.2%) showed “good” or “very good” improvement.

Treatment of striae distensae with a TriPollar radiofrequency device: a pilot study

Manuskiatti W, Boonthaweeyuwat E, Varothai S. *J Dermatolog Treat* 2009; 20: 359–64.

Seventeen females with skin phototypes IV to V and striae received six weekly treatments with a TriPollar radiofrequency device. At 1 week after the final treatment, 38.2% and 11.8% of the subjects were assessed to have 25% to 50% and 51% to 75% improvement of their striae, respectively. No adverse effects were noted.

Treatment of striae distensae with needling therapy versus CO₂ fractional laser

Khater MH, Khattab FM, Abdelhaleem MR. *J Cosmet Laser Ther* 2016; 28: 1–5.

Ten female patients with striae were treated with needling therapy, and another 10 were treated with fractional CO₂ (Deka, Italy) every 1 month for three sessions. The CO₂ settings were spot diameter of 1 to 10 mm according to lesion width, pulse energy of 100 watts, repetition rate of 20 Hz, using a single pass. Nine of 10 needle-treated patients showed improvement, whereas only 5 of 10 CO₂-treated patients showed clinical improvement.

Comparison between the efficacy and safety of platelet-rich plasma vs. microdermabrasion in the treatment of striae distensae: clinical and histopathological study

Ibrahim ZA, El-Tatawy RA, El-Samongy MA, Ali DA. *J Cosmet Dermatol* 2015; 14: 336–46.

Forty patients with striae rubra and 28 patients with striae alba were treated by intradermal injection of PRP alone, microdermabrasion (aluminum oxide/sodium chloride–based system [deep clean (EME-Italy) apparatus]) alone, or combination of PRP and microdermabrasion in the same session every 2 weeks for a maximum of six sessions or until the patients' satisfaction was achieved. PRP alone was more effective than microdermabrasion alone, but it was better to use the combination of both for more and rapid efficacy. With PRP alone or PRP plus microdermabrasion, both striae alba and rubra improved after repeated treatments, but striae rubra improved less than alba. In the microdermabrasion group, striae rubra showed more clinical improvement than alba.

A superficial texture analysis of 70% glycolic acid topical therapy and striae distensae

Mazzarello V, Farace F, Ena P, Fenu G, Mulas P, Piu L, et al. *Plast Reconstr Surg* 2012; 129: 589e–90e.

Double-blind, placebo-controlled trial on 40 patients with both striae rubra and striae alba treated with 70% glycolic acid lotion in a bilateral comparison study. In both types, a significant decrease in furrow width was noted after 6 months. Skin texture parameters analyzed were anisotropy, number of skin furrows, and furrow width, using the silicone replica technique, where silicone casts were analyzed by scanning electron microscopy and imaging software.

Comparison of topical therapy for striae alba (20% glycolic acid/0.05% tretinoin versus 20% glycolic acid/10% L-ascorbic acid)

Ash K, Lord J, Zukowski M, McDaniel DH. *Dermatol Surg* 1998; 24: 849–56.

Ten patients with skin types I to V and abdominal and thigh striae associated with childbirth applied glycolic acid in the morning and either tretinoin or L-ascorbic acid in the evening for a total of 12 weeks. All patients felt that they had improvement of their striae.

Chemical peel of nonfacial skin using glycolic acid gel augmented with TCA and neutralized based on visual staging

Cook KK, Cook WR. *Dermatol Surg* 2000; 26: 994–9.

The authors comment on their experience treating over 3100 patients with nonfacial peels using a combination of 70% glycolic acid gel combined with 40% trichloroacetic acid. It is reported that striae, including atrophic hypopigmented striae, can be improved with this treatment.

Subacute cutaneous lupus erythematosus

Lisa Pappas-Taffer, and Jeffrey P. Callen

Subacute cutaneous lupus erythematosus (SCLE) is a nonscarring, photosensitive variant of cutaneous lupus erythematosus (CLE). Patients can have annular or papulosquamous plaques, or a morphologic combination, that is characteristically in a sun-exposed

distribution. Although SCLE does not scar, it can result in significant dyspigmentation.

Management Strategy

SCLE can be diagnosed clinically, but should be confirmed with skin biopsy. The patient should have a careful history, physical examination, and laboratory studies directed at uncovering systemic manifestations of systemic lupus erythematosus (SLE). Historical details that could help uncover exacerbating factors or that could affect therapeutic choice should be obtained. There are few double-blind, placebo-controlled trials of drugs used in the treatment of SCLE. The goals of management are to treat current lesions and symptoms and to prevent lesion formation. This is done through a combination of patient education, sun protection, and topical and systemic therapies.

The cornerstone of treatment of CLE includes using the most benign drugs possible to achieve disease control. The most common therapies utilized include *photoprotection*, *topical corticosteroids*, *calcineurin inhibitors*, and oral *antimalarials*. Although systemic corticosteroids can be effective, steroid-sparing systemic agents (e.g. *methotrexate*, *mycophenolate mofetil*, *azathioprine*) are preferred to avoid corticosteroid-associated side effects. CLE can affect quality of life. In addition to increased disease control, cosmetic agents used to camouflage lesions or dyspigmentation are important adjuncts.

SCLE can have numerous associations that need to be addressed, including more recalcitrant disease in the setting of tobacco use and a potential risk for neonatal lupus during pregnancy.

Up to 50% of patients with SCLE meet four or more of the criteria of the American College of Rheumatology for classification of SLE. However, they do so by fulfilling the criteria involving skin lesions, photosensitivity, and positive serologies. As a result, those classified as SLE typically only have mild systemic symptoms with major end organ damage occurring in <10%.

Up to 30% of SCLE is induced or exacerbated by a medication. Over 100 different agents have been reported, including antihypertensive agents, statins, antifungals, tumor necrosis factor (TNF) inhibitors, antiepileptics, and proton pump inhibitors. A complete list of the patient's medications will assist in the exclusion of drug-induced SCLE. In the setting of treatment for cancer, SCLE can occur as a

result of chemotherapy exposure, radiation exposure, or as a paraneoplastic syndrome itself.

There are controversial data regarding whether tobacco affects the effectiveness of antimalarial agents. However, multiple studies have reported that cigarette smokers have more severe disease and that a subset of these patients is more refractory to therapies. Hence, patients should be counseled on smoking cessation for the benefit of their skin as well as the increased risk of cardiovascular disease with SLE and possibly CLE.

Specific Investigations

- Ro/SSA antibody
- Exclude systemic disease
- Medication review
- Smoking status

First-Line Therapies

Local therapy

• Cosmetics	E
• Sunscreens, protective clothing, and sun avoidance	A
• High-potency corticosteroids	B
• Topical tacrolimus or pimecrolimus	A
• Topical retinoids	E

Systemic therapy

• Antimalarials (hydroxychloroquine, chloroquine, ± the addition of quinacrine)	A
---	----------

Photoprotective effects of a broad-spectrum sunscreen in ultraviolet-induced cutaneous lupus erythematosus: a randomized, vehicle-controlled, double-blind study

Kuhn A, Gensch K, Haust M, Meuth AM, Boyer F, Dupuy P, et al. J Am Acad Dermatol 2010; 64: 37–48.

Of the 16 CLE patients who had positive provocation study results to UVA or UVB, 88% developed CLE lesions in the vehicle control area, whereas none developed lesions in the broad-spectrum, SPF 60, sunscreen-applied areas.

Discoid lupus erythematosus. Diagnostic features and evaluation of topical corticosteroid therapy

Roenigk HH Jr, Martin JS, Eichorn P, Gilliam JN. Cutis 1980; 25: 281–5.

Despite the long-standing use of high-potency topical corticosteroids as first-line therapy, this is the only randomized, controlled trial examining the efficacy in CLE.

Intralesional triamcinolone is effective for discoid lupus erythematosus of the palms and soles

Callen JP. J Rheumatol 1985; 12: 630–3.

The use of topical calcineurin inhibitors in lupus erythematosus: an overview

Wollina U, Hansel G. J Eur Acad Dermatol Venereol 2008; 22: 1–6.

A good summary of the literature up until 2008 regarding calcineurin inhibitors in CLE, with each table corresponding to all the reported literature for tacrolimus or pimecrolimus response divided by CLE subtype.

Efficacy of tacrolimus 0.1% ointment in cutaneous lupus erythematosus: a multicenter, randomized, double-blind, vehicle-controlled trial

Kuhn A, Gensch K, Haust M, Schneider SW, Bonsmann G, Gaebelein-Wissing N, et al. J Am Acad Dermatol 2011; 65: 54–64.

Significant improvement in all end points was noted in all CLE subtypes after 4 and 8 weeks, but not after 12 weeks. The four patients with SCLE in this study improved, but this was not statistically significant compared with placebo.

Although there are case reports documenting the use of topical retinoids for chronic CLE, there are no reports of using these agents in the setting of SCLE.

Treatment of cutaneous lupus erythematosus with acitretin and hydroxychloroquine

Ruzicka T, Sommerburg C, Goerz G, Kind P, Mensing H. Br J Dermatol 1992; 127: 513–8.

In this multicenter, randomized controlled trial, 50% of patients treated with hydroxychloroquine (HCQ) improved at 8 weeks.

Low blood concentrations of hydroxychloroquine in patients with refractory cutaneous lupus erythematosus: a French multicenter prospective study

Francès C, Cosnes A, Duhaut P, Zahr N, Soutou B, Ingen-Housz-Oro S, et al. Arch Dermatol 2012; 148: 479–84.

In this study of 300 patients with CLE, blood HCQ concentrations greater than 755 ng/mL were associated with a better clinical efficacy.

Monitoring HCQ blood concentrations may be an alternative to the use of a fixed dose of HCQ or to prescribing based on the patient's weight.

The effect of increasing the dose of hydroxychloroquine (HCQ) in patients with refractory cutaneous lupus erythematosus (CLE): an open-label prospective pilot study

Chasset F, Arnaud L, Costedoat-Chalumeau N, Zahr N, Bessis D, Francès C. J Am Acad Dermatol 2016; 74: 693–9.

Of 34 patients (11 with SCLE) who didn't respond clinically to weight-based HCQ after 3 months, with HCQ blood level <750 ng/mL, increasing the dose to 600 mg/day resulted in clinical response in 26/34 (81%) of patients. This clinical response corresponded to HCQ levels of >750 ng/mL. Among responders, the daily dose of HCQ could be decreased back to 400 mg/day in 73% of responders, with one third of responders having sustained cutaneous improvement despite dose reduction, but the remaining two thirds of the responders experiencing a relapse of CLE.

In patients on weight-based HCQ without response, one could attempt a short-term dose increase of HCQ if low HCQ blood levels are present, with the goal of reducing the dose. The former may increase the likelihood of eye toxicity if therapy at higher doses is prolonged. This study also suggests one might consider checking HCQ levels in recalcitrant patients.

Response to antimalarial agents in cutaneous lupus erythematosus: a prospective analysis

Chang AY, Piette EW, Foering KP, Tenhave TR, Okawa J, Werth VP.

Arch Dermatol 2011; 147: 1261–7.

Of 11 patients started on HCQ, 55% were responders. Of 15 patients who were nonresponders to HCQ monotherapy, 67% gained response with the addition of quinacrine, as measured via cutaneous lupus erythematosus disease area and severity index (CLASI).

This report demonstrates the efficacy of combination therapy. The authors use the same algorithmic clinical approach to antimalarial treatment as outlined in this study. HCQ was dosed at 200 to 400 mg/day, and chloroquine was dosed at 250 mg/day for 5 to 7 days per week, both determined by ideal body weight. Quinacrine was dosed at 100 mg/day. If first-line HCQ treatment fails after 3 to 6 months, we add quinacrine. If HCQ–quinacrine treatment fails after 3 to 6 months (or the patient doesn't have access to a compounding pharmacy for quinacrine), we replace HCQ with chloroquine (± quinacrine). Of note, HCQ is first-line due to less eye toxicity than chloroquine (but it is also less efficacious). Quinacrine is a great adjunct to either HCQ or chloroquine, as it does not add to eye toxicity. Use of the HCQ and chloroquine combination is contraindicated due to compounded eye toxicity. Quinacrine must be compounded, and chloroquine is becoming much harder to obtain.

Hydroxychloroquine sulfate treatment is associated with later onset of systemic lupus erythematosus

James JA, Kim-Howard XR, Bruner BF, Jonsson MK, McClain MT, Arbuckle MR, et al. Lupus 2007; 16: 401–9.

Second-Line Therapies

Immunosuppressive Agents

• Mycophenolate mofetil, enteric-coated mycophenolate sodium*	B
• Methotrexate	D
• Azathioprine	D

Immunomodulators

• Dapsone	D
• Thalidomide, lenalidomide	B, C
• Oral retinoids	B

* Double-blind study in SLE population evaluating mucocutaneous (CLE) change, but without the use of a CLE-specific assessment tool.

Mycophenolate sodium for subacute cutaneous lupus erythematosus resistant to standard therapy

Kreuter A, Tomi NS, Weiner SM, Huger M, Altmeyer P, Gambichler T. *Br J Dermatol* 2007; 156: 1321–7.

In this prospective, open-label pilot study, 10 patients with recalcitrant SCLE were treated with enteric-coated mycophenolate sodium as monotherapy. They had statistically significant reductions in CLASI after 3 months of treatment (1440 mg/day). No serious side effects were noted.

This is the equivalent of 1000 mg twice daily of mycophenolate mofetil (MMF). Table 3 is a good summary of MMF (1–3 g/day) and enteric-coated mycophenolate sodium (720–2160 mg/day) efficacy in treating SCLE in multiple case reports and small studies. Pisoni et al. (2005) is the only report of a lack of MMF response in seven SLE/CLE patients (one of which had SCLE); however, patients failed to respond to a median of 4 (range 2–10) different CLE drugs, and treatment efficacy was determined after only 2 months of MMF therapy in 3/7 patients.

Typically MMF in the treatment of CLE is done in combination with antimalarials and topical therapies, with the goal of tapering to the lowest-needed dose/therapies. Authors typically have good response with MMF in patients who fail first-line therapies.

Methotrexate treatment for refractory subacute cutaneous lupus erythematosus

Kuhn A, Specker C, Ruzicka T, Lehmann P. *J Am Acad Dermatol* 2002; 46: 600–3.

Contains a summary of retrospective studies and reports from the literature of treatment with methotrexate (MTX), including 19 CLE patients (8 SCLE patients), with doses ranging from 10 to 25 mg/week.

In patients who fail antimalarials, MTX orally or subcutaneously once weekly is an option.

Efficacy and safety of methotrexate in recalcitrant cutaneous lupus erythematosus: results of a retrospective study in 43 patients

Wenzel J, Brähler S, Bauer R, Bieber T, Tüting T. Br J Dermatol 2005; 153: 157–62.

A retrospective analysis of 43 treatment-refractory CLE patients (15 SCLE) treated with methotrexate 15 to 25 mg weekly. Improvement of CLE occurred in nearly all patients (42/43). *This is a large number of patients with excellent improvement. This agent has not been as successful in the patients the authors have treated, often necessitating the addition of combined antimalarial therapy, or transitioning to MMF, when MTX therapy fails.*

Azathioprine: an effective, corticosteroid-sparing therapy for patients with recalcitrant cutaneous lupus erythematosus or with recalcitrant cutaneous leukocytoclastic vasculitis

Callen JP, Spencer LV, Burruss JB, Holtman J. Arch Dermatol 1991; 127: 515–22.

Report of six patients with refractory CLE (five SCLE) treated with azathioprine 100 to 150 mg/day. Three of six patients had near clearing within 3 months, one of which had palmoplantar ulceration that healed after 6 weeks.

Case series from the 1980s and 1990s have shown successful treatment of CLE (mainly generalized and palmoplantar discoid lupus erythematosus [DLE], but also a series including SCLE) with azathioprine 100 to 150 mg daily.

Dapsone as second-line treatment for cutaneous lupus erythematosus? A retrospective analysis of 34 patients and a review of the literature

Klebes M, Wutte N, Aberer E. Dermatology 2016; 232: 91–6.

This is a retrospective analysis of 34 CLE patients (8 with SCLE) treated with dapsone, most in combination with antimalarials, over a 7-year period. The median dose of dapsone was 100 mg/day (50–125

mg/day) for a mean duration of 16 months (ranging 1–82 months). Forty-one percent of patients improved after 2 months, with 18% showing complete remission within 7 months. The best effect was seen in SCLE patients, with disease remission or improvement in six of eight patients. *Of note, no validated activity measurement tools were used. The authors also summarized the literature (case reports and retrospective analyses that include 137 CLE patients, of which 7 are SCLE) in table 1. Of seven SCLE cases in the literature, all had improvement or clearance with 25 to 150 mg/day dosing.*

Dapsone, given in doses of 25 to 200 mg daily, is especially effective in the treatment of bullous lupus, but case reports and case series have also shown usefulness in the treatment of CLE, especially SCLE lesions and the vasculitic lesions that may accompany SCLE.

Thalidomide in cutaneous lupus erythematosus

Pelle MT, Werth VP. Am J Clin Dermatol 2003; 4: 379–87.

This is a summary of reports of the use of thalidomide for CLE through 2003, specifically the Knop et al. 1983 study of 60 patients showing 90% complete or partial response with 25% peripheral polyneuropathy and the 200 Ordi-Ros et al. prospective study of 22 refractory CLE patients (including 7 SCLE), in which 100 mg daily then reduction to 25 to 50 mg/day was used as maintenance. Initial improvement was noted after 2 weeks and maximum benefit within 3 months, complete remission in 75%, and partial in 25%. Of the 7 SCLE patients, 6/7 cleared with low-dose thalidomide in an average of 2.2 months. After 2013, there are >3 retrospective studies confirming these earlier results. Many demonstrate low-dose thalidomide (50 mg daily) is as effective as higher doses, but does not reduce neurotoxicity (Cuadrado et al. 2005).

Thalidomide in the treatment of refractory cutaneous lupus erythematosus: prognostic factors of clinical outcome

Cortes-Hernandez J, Torres-Salido M, Castro-Marrero J, Vilardell-Tarres M, Ordi-Ros J. Br J Dermatol 2012; 166: 616–23.

In this prospective observational study, 60 patients with refractory CLE (18 SCLE) on prednisone and antimalarials were treated with thalidomide 100 mg/day and followed for a mean of 8 years (range 2–18). Once complete clinical improvement was achieved, dose reduction to 50 mg daily then 50 mg alternating days occurred. Ninety-eight percent achieved response, with 85% achieving complete response, typically within a mean of 8 weeks (range 3–16). Mean

duration of therapy was 6 months (3–36 months). By the end of the 8 years, 70% who had attained complete remission had at least one relapse, whereas the rest (30%) remained in remission despite medication withdrawal after at least 8 years of follow-up. Neurologic symptoms occurred in 18% of patients (reported as high as 45% in retrospective studies) with nerve conduction studies being positive in half of the cases. Neurologic symptoms and signs on electromyography (EMG) resolved after 12 months (range 6–18) status postwithdrawal.

This is the first prospective thalidomide study utilizing CLASI to measure clinical response. Patients with SCLE had a lower relapse rate and required a lower cumulative dose and duration of therapy of thalidomide compared with other CLE subtypes.

Thalidomide (50–100 mg/day) has been shown to be highly efficacious in the treatment of CLE, including SCLE, and much less effective for SLE (can induce SLE flare). Numerous retrospective studies, and the previously mentioned prospective study, show on average 80% of patients achieving complete response. CLE responds quickly, beginning at 2 to 4 weeks, and doses can often be tapered lower after improvement. Thalidomide should only be used to treat severe, refractory CLE at the lowest dose possible. Studies have shown that starting with a low dose is as effective as higher doses, but unfortunately has not been shown to reduce the incidence of neurotoxicity. Although highly efficacious, it is reserved as second-line therapy because of its cost, the degree of monitoring by the System for Thalidomide Education and Prescribing Safety (STEPS) protocol, its teratogenicity, and adverse effects, including peripheral neuropathy. Thalidomide works well as a rescue medication or for maintenance at low or intermittent dosing (e.g., 25 mg every 2–3 days) to try and minimize toxicity.

Lenalidomide treatment of cutaneous lupus erythematosus: the Mayo Clinic experience

Kindle SA, Wetter DA, Davis MD, Pittelkow MR, Sciallis GF. *Int J Dermatol* 2016; 55(8): e431-9. <http://dx.doi.org/10.1111/ijd.13226>. PMID: 26873674.

This is a retrospective analysis of nine patients with treatment-refractory CLE (six DLE, one SCLE) treated with lenalidomide 5 to 10 mg/day. Patients were refractory to at least one antimalarial and one immunosuppressive agent. Patients with lupus panniculitis (two) did not respond. Seven of nine DLE and SCLE patients achieved either complete or partial response, with the initial response occurring

within 2 to 3 months.

Kindle et al. includes a review of prior studies (one case report and three prospective studies), which included five SCLE patients treated with lenalidomide 5 to 10 mg/day. Collectively, two cases of complete response and two cases of partial response in SCLE patients treated with lenalidomide. Braunstein et al. (2012) found four of five highly recalcitrant CLE patients (two with SCLE) treated with 5 mg/day lenalidomide had clinical improvement. One responder developed SLE, suggesting there might be an increased risk of developing a severe SLE flare with lenalidomide. Cortes-Hernandez et al. (2012) treated 15 CLE patients (2 with SCLE) prospectively with 5 to 10 mg/day lenalidomide, then tapered to clinical response. Eighty-six percent achieved complete response (CLASI 0), but clinical response was frequent (75%), occurring 2 to 8 weeks after drug withdrawal. Only two patients, those with SCLE, obtained a sustained remission after withdrawing medication. Okon et al. (2014) reported the results of a 52-week prospective trial of five treatment-refractory CLE patients treated with 5 mg daily for 6 weeks followed by 6 mg every other day in those who responded, or increased to 10 mg/day in nonresponders. All five patients had significant reductions in CLASI-measured disease activity at 12 weeks.

Lenalidomide is a thalidomide derivative with a better side effect profile than thalidomide. Lenalidomide is helpful in treating refractory CLE, similar to thalidomide, but with less associated sedation, constipation, peripheral neuropathy, and thrombophilic effects than with thalidomide. Similar to thalidomide, it does not work well in the treatment of SLE. Lenalidomide is currently being evaluated in a randomized controlled trial for the treatment of refractory CLE.

Treatment of cutaneous lupus erythematosus with acitretin and hydroxychloroquine

Ruzicka T, Sommerburg C, Goerz G, Kind P, Mensing H. Br J Dermatol 1992; 127: 513–8.

In this randomized, double-blind, multicenter study, overall improvement was noticed in 13/28 (46%) of patients treated with acitretin 50 mg/day and hydroxychloroquine 400 mg/day, with five of the six SCLE patients having complete clearance. The median duration of treatment was 56.5 days.

Subacute cutaneous lupus erythematosus: report of a patient

who subsequently developed a meningioma and whose skin lesions were treated with isotretinoin

Richardson TI, Cohen PR. *Cutis* 2000; 66: 183–8.

This is a good review of the literature regarding malignancy-associated SCLE (table 1), as well as the use of acitretin and isotretinoin for CLE. Acitretin has been shown to be effective in 50% of CLE patients in a randomized controlled trial, whereas isotretinoin's efficacy has been seen in multiple case reports of three SCLE patients treated with 0.7 to 1 mg/kg with great response (D'Erme et al; 2012. Farner et al. 1990; Newtown et al. 1998). The response is often not durable, and low-dose maintenance therapy is needed. *Although use in SCLE is limited, it is still a valid option with the advantage of a shorter half-life than acitretin for women of child-bearing age.*

Alitretinoin for cutaneous lupus erythematosus

Kuhn A, Patsinakidis N, Luger T. *J Am Acad Dermatol* 2012; 67: e123–6.

The patient with SCLE showed total clearance after 2 months of therapy with 30 mg/day.

Third-Line Therapies

• Intravenous immunoglobulin	D
• Cyclophosphamide*	D
• Rituximab (anti-CD20 chimeric antibody)*	E
• Belimumab (anti-BLys monoclonal antibody) *	E
• Antiinterferon alpha monoclonal antibody (investigational)	A
• Pulsed dye laser	D

Historical and/or experimental therapies without proven efficacy and/or therapies with unfavorable risk–benefit ratio

• Clofazimine	A
• Phenytoin	B
• Gold	B
• Cytokine therapy (interferon, CD4 monoclonal antibody)	D
• TNF inhibitors	D
• Ustekinumab	E
• Leflunomide	E

* Double-blind study in SLE population evaluating mucocutaneous (CLE) change, but without the use of a CLE-specific assessment tool

Efficacy of intravenous immunoglobulin monotherapy in patients with cutaneous lupus erythematosus: results of proof-of-concept study

Ky C, Swasdibutra B, Khademi S, Desai S, Laquer V, Grando SA. *Dermatol Reports* 2015; 7: 5804.

In this open-label prospective study, 16 treatment-refractory CLE patients (subtypes not listed) were treated as monotherapy with IVIG 2g/kg/month for 3 months and followed for 6 months off the drug. The study showed rapid and persistent decreases in disease activity within a few weeks (as measured by CLASI). Three treatment cycles (3 months) were sufficient to achieve clinical response, but three patients had mild relapses.

In general, one could consider IVIG a bridge therapy while waiting for another systemic medication to take effect or to abort an acute flare. There have been a handful of prospective studies with positive results; however, De Pita et al. (1997) showed no improvement of refractory CLE with IVIG 1.5 g/kg/day (a lower dose) monthly for 1 year.

Pulse cyclophosphamide treatment for severe refractory cutaneous lupus erythematosus

Raptopoulou A, Linardakis C, Sidiropoulos P, Kritikos HD, Boumpas DT. *Lupus* 2010; 19: 744–7.

Six patients with severe, refractory SCLE were treated with

monthly cyclophosphamide pulses, followed by azathioprine 100 to 200 mg/day as maintenance therapy. HCQ was continued as well. Significant improvement in CLASI was seen in all patients, with complete remission in four and partial remission in two patients. The authors report no relapses and no major adverse events in more than 3 years' follow-up.

Refractory subacute cutaneous lupus erythematosus successfully treated with rituximab

Kieu V, O'Brien T, Yap LM, Baker C, Foley P, Mason G, et al. *Australas J Dermatol* 2009; 50: 2002–6.

This is a case report of a patient with treatment-refractory SCLE. After IV rituximab (375 mg/m²) weekly for 4 weeks, she had regression of skin lesions at 16 weeks. At 11-month follow-up, SCLE recurred, and the same rituximab regimen was repeated with maintenance therapy every 8 weeks for 2 years, with ongoing disease remission.

Brief report: responses to rituximab suggest B cell-independent inflammation in cutaneous systemic lupus erythematosus

Vital EM, Wittmann M, Edward S, Yusof MY, MacIver H, Pease CT, et al. *Arthritis Rheumatol* 2015; 67: 1586–91.

In this report, 82 patients with SLE who were receiving rituximab were prospectively studied. Among patients with SLE, one of two patients with baseline SCLE responded to rituximab. Flares of new SCLE and DLE occurred in 12 patients who either had no skin disease at baseline or had acute CLE only at baseline (i.e., a switch in subtype) at the time of near-complete or complete B-cell depletion.

This study suggests that rituximab does not work well for CLE, with the exception of acute CLE, and patients with SLE can have CLE flares despite a lack of skin involvement at baseline.

Effects of belimumab, a B lymphocyte stimulator-specific inhibitor, on disease activity across multiple organ domains in patients with systemic lupus erythematosus: combined results from two phase III trials

Manzi S, Sanchez-Guerrero J, Merrill JT, Furie R, Gladman D, Navarra SV, et al. *Ann Rheum Dis* 2012; 71: 1833–8.

In phase III trials, belimumab (approved for SLE) plus standard therapy showed improvement in mucocutaneous parameters,

specifically rash, mucosal ulcers, and alopecia.

It is unclear how well belimumab works for CLE, as these studies employed SLE-specific rather than CLE-specific tools to assess activity and monitor outcomes. It is thought to work better for SLE than for CLE.

Safety and efficacy of sifilimumab, an anti IFN- α monoclonal antibody, in a phase 2b study of moderate to severe systemic lupus erythematosus (SLE)

Khamashta MMJ, Werth VP, Furie R, Kalunian K, Illeis GG, Drappas J, et al. Arthritis Rheum 2014; 66: 3530–1.

Anifrolumab, an anti-Interferon- α receptor monoclonal antibody, in moderate-to-severe systemic lupus erythematosus

Furie R, Khamashta M, Merrill JT, Werth VP, Kalunian K, Brohawn P, et al. Arthritis Rheumatol 2017; 69: 376–86.

Recently, phase II trials demonstrated reduced mucocutaneous activity and are promising regarding SCLE therapy.

Pulsed dye laser treatment of subacute cutaneous lupus erythematosus

Gupta G, Roberts DT. Clin Exp Dermatol 1999; 24: 498–9.

A recalcitrant SCLE patient was successfully treated with pulsed dye laser (PDL) (585 nm, 450-ms pulse duration, 5-mm spot size, and fluence 5.3 J/cm²) on four occasions, 1 month apart, resulting in marked improvement of the erythema.

Subcorneal pustular dermatosis

Gorav N. Wali, and Vanessa Venning

Subcorneal pustular dermatosis is a rare, chronic, neutrophilic dermatosis of unknown etiology, in which flaccid pustules and vesicopustules, classically resembling a hypopyon, arise in crops on truncal and flexural skin. The condition can occur at any age, more commonly in females. It usually follows a relapsing and remitting course, but generally the patient remains systemically well.

The condition may be difficult to differentiate from other

vesiculopustular dermatoses. Some cases may be a variant of pustular psoriasis, whereas others appear to overlap with the subcorneal pustular variant of IgA pemphigus. In “classical” subcorneal pustular dermatosis, immunofluorescence studies are negative; however, there are patients with identical clinical and histologic features that have intercellular IgA deposition in the upper epidermis targeting desmosal components, most commonly desmocollins.

Subcorneal pustular dermatosis is associated with monoclonal IgA paraproteinemia and myeloma, which may occur many years after presentation. Other reported associations are pyoderma gangrenosum, inflammatory bowel disease, rheumatoid arthritis, infections (in particular *Mycoplasma pneumoniae*), and drugs.

Management Strategy

Dapsone is the treatment of choice (25–200 mg daily) and normally results in resolution of the rash within 4 weeks; the drug usually needs to be continued long term because relapse is common on withdrawal of therapy. After control is gained, the dose should be tapered to the lowest dose required to maintain remission. Other sulfones (*sulfapyridine*, *salazosulfapyridine*) have also been found to be beneficial in isolated reports.

In a proportion of cases the response to dapsone is poor; *retinoids* (formerly etretinate, now replaced by acitretin) have been substituted with success, using an initial dose of 0.5 to 1.0 mg/kg daily and then reducing to the lowest dose that will maintain control. Alternatively, for those unable to tolerate dapsone in the dose required, retinoids have been added to dapsone; this has enabled lower doses of each to be used. There are a few case reports detailing good response to *phototherapy*—*psoralen and UVA (PUVA)*, *narrowband UVB*, or *broadband UVB*—in combination with dapsone or retinoids.

Both *topical* and *systemic corticosteroids* have been reported in isolated cases to provide some degree of control. Unacceptably high doses of systemic corticosteroids may be required, but combination with other treatments may allow control with lower doses.

A number of *dapsone*-resistant cases have been treated with novel therapies such as *anti-TNF α inhibitors*, but experience with these newer agents is limited.

Subcorneal pustular dermatosis tends to run a chronic course. Maintenance of a continuing beneficial response may be difficult, as

may be inferred from the extensive range of treatment options described. Although *dapsone* appears to offer the best chance of a good therapeutic response, treatment regimens for this condition have not been formally evaluated.

Specific Investigations

- Full blood count
- Immunoglobulin levels
- Serum protein electrophoresis
- Bence–Jones protein
- Autoantibodies
- Skin biopsy with immunofluorescence

Subcorneal pustular dermatosis: 50 years on

Cheng S, Edmonds E, Ben-Gashir M, Yu RC. Clin Exp Dermatol 2008; 33: 229–33.

A useful review of the literature. The authors discuss the relationship between subcorneal IgA pemphigus and classical subcorneal pustular dermatosis and accept that several authorities now consider this former subgroup to be a rare variant of pemphigus.

Subcorneal pustular dermatosis: a clinical study of ten patients

Lutz ME, Daoud MS, McEvoy MT, Gibson LE. Cutis 1998; 61: 203–8.

Four of the seven patients in whom immunoglobulins were checked had paraproteinemia: three of IgA and one of IgG type; none of these patients had IgA deposits on direct immunofluorescence.

Subcorneal pustular dermatosis and IgA λ myeloma: an uncommon association but probably not coincidental

Vaccaro M, Cannavó SP, Guarneri F. Eur J Dermatol 1999; 9: 644–6.

A case report of IgA λ myeloma associated with subcorneal pustular dermatosis. Treatment of the underlying myeloma had no effect on the skin disease.

A case of subcorneal pustular dermatosis with IgG monoclonal gammopathy of undetermined significance: a rare association

Kavala M, Karadağ AS, Zindancı I, Turkoglu Z, Ozturk E, Zemheri E, et al. Int J Dermatol 2015; 54: 551–3.

A case of subcorneal pustular dermatosis associated with IgG kappa monoclonal gammopathy of uncertain significance.

Sneddon–Wilkinson disease in association with rheumatoid arthritis

Butt A, Burge SM. Br J Dermatol 1995; 132: 313–5.

Useful overview of all reported cases associated with either seronegative or seropositive arthritis.

Subcorneal pustular dermatosis triggered by *Mycoplasma pneumoniae*: a rare clinical association

Bohelay G, Duong TA, Ortonne N, Chosidow O, Valeyrie-Allanore L. J Eur Acad Dermatol Venereol 2015; 29:1022–5.

A case of subcorneal pustular dermatosis in association with *Mycoplasma pneumoniae* pneumonitis. Literature review identified seven cases associated with *M. pneumoniae*.

Sneddon-Wilkinson disease induced by sorafenib in a patient with advanced hepatocellular carcinoma

Tajiri K, Nakajima T, Kawai K, Minemura M, Sugiyama T. Intern Med 2015; 54: 597–600.

A case of subcorneal pustular dermatosis that developed after sorafenib administration. It improved after cessation of sorafenib and worsened by its readministration.

First-Line Therapy

• Dapsone	C
-----------	---

Subcorneal pustular dermatosis

Sneddon IB, Wilkinson DS. Br J Dermatol 1956; 68: 385–93.

Three of six patients responded to dapsone 50 to 100 mg daily.

Sneddon–Wilkinson disease in association with rheumatoid

arthritis

Butt A, Burge SM. Br J Dermatol 1995; 132: 313–5.

A further five patients who responded to dapsone.

Subcorneal pustular dermatosis and IgA gammopathy

Burrows D, Bingham EA. Br J Dermatol 1984; 111: 91–3.

The addition of etretinate enabled control in a patient intolerant of higher-dose dapsone.

Sneddon–Wilkinson disease. Four case reports

Launay F, Albes B, Bayle P, Carriere M, Lamant L, Bazex J. Rev Med Interne 2004; 25: 154–9.

Three of four patients responded to dapsone.

Subcorneal pustular dermatosis in a young boy

Garg BR, Sait MA, Baruah MC. Indian J Dermatol 1985; 30: 21–3.

Subcorneal pustular dermatosis in childhood: a case report and review of the literature

Scalvenzi M, Palmisano F, Annunziata MC, Mezza E, Cozzolino I, Costa C. Case Rep Dermatol Med 2013; 2013: 5.

<http://dx.doi.org/10.1155/2013/424797>. Article ID 424797.

Two reports of successful response to dapsone in children.

Second-Line Therapies

• Sulfones	D
• Corticosteroids	D
• Etretinate (no longer marketed)	D
• Acitretin	E
• PUVA	D
• Narrowband UVB	E
• Broadband UVB	E

Subcorneal pustular dermatosis

Sneddon IB, Wilkinson DS. Br J Dermatol 1956; 68: 385–93.

Two patients were controlled on sulfapyridine 1 g twice daily.

Subcorneal pustular dermatosis in children

Johnson SAM, Cripps DJ. Arch Dermatol 1974; 109: 73–7.

Two children were controlled, but not cleared, with topical and systemic corticosteroids.

Role of tumor necrosis factor- α in Sneddon–Wilkinson subcorneal pustular dermatosis

Grob JJ, Mege JL, Capo C, Jancovicci E, Fournier JR, Bongrand P, et al. J Am Acad Dermatol 1991; 25: 944–7.

Methylprednisolone induced remission in this patient who failed to respond to dapsone, etretinate, or plasma exchange. A maintenance dose of 12 mg daily was required.

An unusual severe case of subcorneal pustular dermatosis treated with cyclosporine and prednisolone

Zachariae CO, Rossen K, Weismann K. Acta Derm Venereol 2000; 80: 386–7.

After failure with dapsone and prednisolone (because of abnormal liver enzymes), ciclosporin (400 mg daily) was substituted for dapsone; onset of resolution was swift, and ciclosporin was stopped after 3 weeks; prednisolone was slowly withdrawn over 2 months with no recurrence.

Treatment of subcorneal pustulosis by etretinate

Iandoli R, Monfrecola G. *Dermatologica* 1987; 175: 235–8.

A patient who failed to respond to dapsone 300 mg daily and topical corticosteroids responded well to etretinate 1 mg/kg daily. A maintenance dose of 0.75 mg/kg daily was required.

A case of subcorneal pustular dermatosis in association with monoclonal IgA gammopathy successfully treated with acitretin

Canpolat F, Akipinar H, Çevirgen C, Eskioğlu F, Öztürk E. *J Dermatol Treat* 2010; 21: 114–6.

A patient who failed to respond to dapsone and topical corticosteroids subsequently responded to acitretin 25 mg daily within 2 weeks. This was reduced to 10 mg daily after 3 months and stopped after 4 months with no subsequent relapse.

Successful treatment of subcorneal pustular dermatosis (Sneddon–Wilkinson disease) by acitretin: report of a case

Marlière V, Beylot-Barry M, Beylot C, Doutre M-S. *Dermatology* 1999; 199: 153–5.

This paper reviews the use of retinoids for subcorneal pustular dermatosis.

Subcorneal pustular dermatosis treated with PUVA therapy

Bauwens M, De Coninck A, Roseeuw D. *Dermatology* 1999; 198: 203–5.

A patient resistant to dapsone alone responded well to combination with PUVA. This paper contains a useful overview of PUVA therapy.

Subcorneal pustular dermatosis (Sneddon–Wilkinson disease) treated with narrowband (TL-01) UVB phototherapy

Cameron H, Dawe RS. *Br J Dermatol* 1997; 137: 150–1.

This patient was initially controlled with minocycline 200 mg daily and topical corticosteroids, but suffered a flare that was poorly responsive. Narrowband UVB phototherapy enabled corticosteroids

to be withdrawn and control to be maintained with minocycline alone.

Subcorneal pustular dermatosis responsive to narrowband (TL-01) UVB phototherapy

Orton DI, George SA. Br J Dermatol 1997; 137: 149–50.

After long-term PUVA treatment this patient achieved a satisfactory response with narrowband UVB phototherapy.

Third-Line Therapies

• Etanercept	E
• Infliximab	E
• Tacalcitol (1- α ,24-dihydroxyvitamin D ₃)	E
• Maxacalcitol (1- α ,25-dihydroxy-22-oxacalcitriol)	E
• Mizoribine	E
• Ketoconazole	E
• Tetracycline, minocycline	E
• Benzylpenicillin	E
• Vitamin E	E
• Mebhydrolin	E
• Intravenous immunoglobulins	E
• Ciclosporin	E

Sneddon–Wilkinson disease treated with etanercept: report of two cases

Berk DR, Hurt MA, Mann C, Sheinbein D. Clin Exp Dermatol 2009; 34: 347–51.

Two patients with refractory disease responded to etanercept 50 mg twice weekly (in combination with low-dose acitretin in one case).

Early but not lasting improvement of recalcitrant subcorneal pustular dermatosis (Sneddon–Wilkinson disease) after infliximab therapy: relationships with variations in cytokine levels in suction blister fluids

Bonifati C, Trento E, Cordiali Fei P, Muscardin L, Amantea A, Carducci M. Clin Exp Dermatol 2005; 30: 662–5.

Infliximab (antitumor necrosis factor alpha antibody): a novel, highly effective treatment of recalcitrant subcorneal pustular dermatosis (Sneddon–Wilkinson disease)

Voigtlander C, Luftl M, Schuler G, Hertl M. Arch Dermatol 2001; 137: 1571–4.

The case of SLE associated Sneddon-Wilkinson pustular disease successfully and safely treated with infliximab

Naretto C, Baldovino S, Rossi E, Spriano M, Roccatello D. Lupus 2009; 18: 856–7.

Three reports of initial, but in one case not sustained, benefit of infliximab given at standard doses.

Recalcitrant subcorneal pustular dermatosis and bullous pemphigoid treated with mizoribine, an immunosuppressive purine biosynthesis inhibitor

Kono T, Terashima T, Oura H, Ishii M, Taniguchi S, Muramatsu T. Br J Dermatol 2000; 143: 1328–30.

Two patients responded to mizoribine (Bredinin) 150 mg daily, one to mizoribine alone, the other with combined prednisolone 50 mg and mizoribine 150 mg daily.

A case of subcorneal pustular dermatosis treated with tacalcitol (1-alpha,24-dihydroxyvitamin D₃)

Kawaguchi M, Mitsunashi Y, Kondo S. J Dermatol 2000; 27: 669–72.

Therapie der pustulosis subcornealis Sneddon Wilkinson mit tacalcitol

Muhlhoff C, Megahed M. Hautarzt 2009; 60: 360–70.

Two cases of topical vitamin D₃ leading to sustained resolution of lesions.

Successful treatment of subcorneal pustular dermatosis with maxacalcitol

Hoshina D, Tsujiwaki M, Furuya K. Clin Exp Dermatol 2016; 41: 102–3.

A case controlled with topical maxacalcitol (1- α ,25-dihydroxy-22-oxacalcitriol), a vitamin D₃ analog.

Ketoconazole as a therapeutic modality in subcorneal pustular dermatosis

Verma KK, Pasricha JS. Acta Derm Venereol 1977; 77: 407–8.

After failing to respond to dapsone, a patient achieved remission using ketoconazole 200 mg daily. Although this was initially started in conjunction with dapsone, withdrawal of ketoconazole led to a disease flare; the patient was subsequently satisfactorily controlled on ketoconazole alone.

Subcorneal pustular dermatosis (Sneddon–Wilkinson)

Mandel EH, Gonzales V. Arch Dermatol 1969; 99: 246–7.

Tetracycline 250 mg four times daily controlled new pustule formation.

Subcorneal pustular dermatosis controlled by vitamin E

Ayres S, Mihan R. Arch Dermatol 1974; 109: 74.

Vitamin E (400 IU D- α -tocopheryl acetate), when added to prednisolone 40 mg daily, enabled the dosage of prednisolone to be reduced to 5 mg daily.

Subcorneale pustulose Sneddon–Wilkinson: therapie mit mebhydrolin

Dorittke P, Wassilew SW. Z Hautkr 1988; 63: 1025–7.

Treatment with mebhydrolin 50 mg three times daily was successful.

Subcorneal pustulosis with combined lack of IgG/IgM and monoclonal gammopathy type IgA/kappa

Rasch A, Schimmer M, Sander CA. J Dtsch Dermatol Ges 2009; 7: 693–6.

Intravenous immunoglobulins 0.2g/kg in a patient with IgG/IgM deficiency resulted in complete resolution of lesions, with three

weekly cycles maintaining remission.

Subcutaneous fat necrosis of the newborn

Bernice Krafchik

Subcutaneous fat necrosis of the newborn (SFN) is a rare, self-limited, lobular panniculitis of the skin that occurs in the first few weeks of life. The eruption affects areas where fat tissue is found and

usually presents with a clinical picture of erythema and induration over the back of the proximal extremities, the upper back, buttocks, and thighs. Individual lesions vary from a few millimeters to several centimeters and may coalesce. The etiology/pathogenesis is unknown, but most infants suffer from some form of perinatal difficulty that includes asphyxia, peripheral hypoxia (tissue) or hypoxemia (blood), meconium aspiration, and maternal diabetes. A number of recent articles have described infants who have developed SFN after being treated with total body cooling for hypoxic ischemic encephalopathy (HIE). It is unlikely that the HIE is the cause of the SFN as SFN has also been described in patients receiving hypothermia for cardiac surgery. Most infants with SFN have been delivered by cesarean section, making birth trauma an unlikely cause.

The most important complication seen with SFN is hypercalcemia; it occurred in one third of patients admitted to a hospital for evaluation and treatment. The cause of the hypercalcemia is unknown; one theory postulates that increased calcium absorption occurs as a result of unregulated extrarenal 1,25-dihydroxyvitamin D. In severe cases of hypercalcemia, hypercalciuria and nephrocalcinosis may occur, increasing the possibility of seizures and death. Other symptoms of hypercalcemia are nonspecific; they include fever, vomiting, lethargy, constipation, feeding difficulties, and failure to thrive. Very rarely thrombocytopenia, hypoglycemia, anemia, hypervitaminosis D, and hypertriglyceridemia may occur.

SFN resolves spontaneously within 3 to 6 months leaving normal skin or small pitted scars and occasionally an absence of fat tissue in the affected area. Treatment of the lesions is seldom necessary, except in the rare instances when liquefaction of the fat tissue occurs or when hypercalcemia or other blood chemistry abnormalities develop.

Management Strategy

Biopsy, with its typical pathology, is usually not warranted as the clinical picture is typical. Aspiration biopsy can be helpful in establishing the diagnosis. It is a simple alternative to a punch biopsy in lesions that are not clinically diagnostic. Magnetic resonance imaging (MRI) and ultrasound investigation demonstrate characteristic features and highlight nephrocalcinosis and other areas of calcification if present. Patients should have blood work to ascertain whether blood calcium is high. It is important to recognize

that serum calcium in both normal patients and those with SFN may be low in the first 2 weeks of life. Infants with SFN should be monitored weekly to see if there is any increase in blood calcium values, and if levels of calcium increase, blood should be checked biweekly for up to 6 months. If the infant is sick, tests for other abnormal indices should be performed.

Treatment is determined by the levels of hypercalcemia and hypercalciuria. If levels are marginally raised, monitoring the serum and urine levels of calcium may be all that is necessary, and a spontaneous return to normal levels often occurs. If there are mildly increased levels that persist or a further rise occurs, treatment should be instigated. Mild hypercalcemia is treated by the *withdrawal of vitamin D* and by using a *low-calcium diet*. This is best accomplished by breastfeeding as breast milk is low in calcium and vitamin D, and if this strategy produces no benefit or calcium continues to rise, *intravenous saline* is used to promote the normal excretion of calcium. *Furosemide* promotes further excretion. Other options for nonresponders include *calcitonin*, oral *corticosteroids* (hydrocortisone and prednisone), and *bisphosphonate* (pamidronate and others). Pamidronate works by interfering with bone resorption. It is more potent than saline and calcitonin and starts working in 2 days. The latter treatments should be instituted with the help of a pediatric endocrinologist.

The rare occurrence of liquefaction in the lesions should be removed with a large-bore needle.

Specific Investigations

- Biopsy or fine needle aspiration for diagnosis (if required)
- Renal ultrasound for nephrocalcinosis, nephrolithiasis
- MRI of torso if indicated by high calcium levels
- Serum and urine calcium weekly for 6 months, biweekly if elevated
- Monitor urine calcium/creatinine ratio

Fine-needle aspiration as a method of diagnosis of subcutaneous fat necrosis of the newborn

Schubert PT, Razak R, Vermaak A, Jordaan HF. *Pediatr Dermatol* 2016; 33: e220–1.

The article reviews previous findings by the same authors, emphasizing the advantages of fine needle aspiration: it is thought to be as helpful as punch biopsy. The typical pathologic picture includes clumped lobules of fat with opaque cytoplasm and/or necrotic aspirates of dispersed fat cells with opaque cytoplasm, foamy macrophages, multinucleated giant cells, lymphocytes and neutrophils, and the characteristic radially oriented and loose refractile needle-shaped crystals in the cytoplasm of the fat cells lying in the necrotic background.

Subcutaneous fat necrosis in a newborn after brief therapeutic cooling hypothermia: ultrasonographic examination

Tognetti L, Fillippou G, Bertrando S, Picerno V, Buornocore G, Frediani B, et al. *Pediatr Dermatol* 2015; 32: 427–9.

The authors describe the cutaneous and subcutaneous features of ultrasounds performed on patients who had developed SFN after the use of therapeutic hypothermia to treat HIE. The ultrasound procedures were easy to perform. Newborn adipose tissue is mainly composed of high-melting-point saturated fatty acids. Low temperatures can induce fat crystallization and necrosis. Increased local pressure, hypoperfusion of fat cells, and tissue hypoxia stimulate saturated fatty acid deposition and are thought to be mechanisms of the SFN. These changes appears as hypoechoic shadows on ultrasound.

Subcutaneous fat necrosis of the newborn: a review of eleven cases

Burden AD, Krafchik BR. *Pediatr Dermatol* 1999; 16: 384–7.

Ten of the patients had been delivered by cesarean section for fetal distress: four developed hypercalcemia. Patients should be monitored for 6 months even if the SFN lesions have disappeared, as hypercalcemia can still occur without clinical lesions.

First-Line Therapies

• No treatment for the majority of patients	C
• Low-calcium and low-vitamin D diet (either breast milk or formula)	C

Severe hypercalcemia due to subcutaneous fat necrosis: presentation, management and complications

Shumer DE, Thaker V, Taylor GA, Wassner AJ. Arch Dis Child Fetal Neonatal Ed 2014; 99: F419–21.

The authors of this article followed seven children with severe hypercalcemia associated with SFN described in the past literature as an unusual event with an estimated incidence of between 36% and 56%; the hypercalcemia and follow-up were short. The hypercalcemia in this study occurred within 6 weeks of birth, and nephrocalcinosis, found on ultrasonography, was the most frequent complication occurring in 83%. In their 4-year follow-up the nephrocalcinosis persisted, unlike the information in prior reports. No associated renal problems were reported. Other findings were fevers without infection and mild eosinophilia. Treatments varied; all were treated with intravenous hydration and formula that has low calcium. Glucocorticoids (prednisone and methyl prednisolone) were used (1 to 2 mg/mg/kg/dose). Calcitonin was not helpful.

Extensive subcutaneous fat necrosis of the newborn associated with therapeutic hypothermia

Hogeling M, Meddles K, Berk DR, Bruckner A, Shimotake T, Frieden I. Pediatr Dermatol 2012; 29: 59–63.

The authors of this article reviewed the increased occurrence of SFN associated with the treatment of HIE with hypothermia. The SFN usually develops from 1 to 4 weeks, but can occur as early as 72 hours. Hypercalcemia occurred in a third of the patients studied. Control of hypercalcemia may prevent cardiac and renal complications and metastatic calcification.

Second-Line Therapies

• Intravenous saline at 1.5 times the normal maintenance dose	D
• Furosemide 1 to 1.5 mg/kg every 6 to 12 hours for 5 days	D

Third-Line Therapies

• Oral or IV steroids (prednisone and methyl prednisone, 1–2 mg/kg/per dose for 5 days)	C
• Subcutaneous calcitonin (4–8 IU/kg every 6–12 hours for 2–3 days)	E
• Bisphosphonates (pamidronate 0.25–0.5 mg/kg/dose for 2–4 days)	D

Neonatal hypercalcemia secondary to subcutaneous fat necrosis successfully treated with pamidronate. A case series and literature review

Samedi VM, Yusuf K, Yee W, Obiad H, Al Awad EH. AJP Report 2014; 4: e93–6.

The authors stress that with increasing use of therapeutic cooling for the treatment of HIE with or without symptoms, patients who develop SFN should be monitored for the development of hypercalcemia, which may be very severe, and treatment should be instigated as soon as needed. They include hyperhydration, diuretics, corticosteroids, and bisphosphonates.

Most of the articles regarding the use of bisphosphonates for the treatment of patients with SFN have been single case studies. In one article, after adding calcitonin to the pamidronate, which had already been started, the effect of the combination was immediate. The authors suggest that calcitonin works faster (12–48 hours) than pamidronate, that it takes 2–4 days to work, and that both medications are more efficacious when used together.

Sweet syndrome

Asha Gowda, Karolyn A. Wanat, and William D. James

Sweet syndrome is a neutrophilic dermatosis characterized clinically by multiple painful, well-demarcated, nonscarring, erythematous plaques or pustules on the face, neck, upper trunk, and extremities. There can be a pseudovesicular appearance. Fever, leukocytosis, arthralgias, myalgias, headaches, and general malaise may occur. Oral, ocular, and internal organ involvement is rare. On histopathology, there is a diffuse neutrophilic infiltrate in the upper dermis without evidence of primary leukocytoclastic vasculitis. Neutrophilic dermatosis of the dorsal hands (NDDH) is classified as

an anatomically limited subset of Sweet syndrome.

Management Strategy

Sweet syndrome is often idiopathic, but may be associated with malignancy (most commonly acute myelogenous leukemia, but also lymphomas, dysproteinemias, and carcinomas), inflammatory bowel disease, infection (commonly *Streptococcus* or *Yersinia*), medication, radiation, and pregnancy. Workup includes skin biopsy, complete physical examination, and laboratory studies. Treatment of the underlying associated condition or discontinuation of the causative medication may lead to resolution of skin lesions. The standard treatment is *corticosteroids*. For patients with contraindications to corticosteroids, or for therapeutic failures, second-line therapies may be used.

Specific Investigations

- Complete blood count with differential
- Erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP)
- Cultures as indicated by history and physical examination
- Malignancy screening: age-appropriate screening, evaluation if hematologic abnormalities exist, and consideration of serum protein/serum immunofixation electrophoresis; bone marrow biopsy may be considered
- Pregnancy test (in women of childbearing potential)
- Medication history

First-Line Therapies

• Oral corticosteroids	C
• Topical and intralesional corticosteroids	C

Sweet's syndrome: a review of current treatment options

Cohen PR, Kurzrock R. Am J Clin Dermatol 2002; 3: 117–31.

A review of the literature regarding treatment for Sweet syndrome.

Corticosteroid therapy (oral prednisone 0.5–1.5 mg/kg daily tapered over 4–6 weeks) results in rapid relief of systemic symptoms (within 1–2 days) and skin lesions within 3 to 9 days. Up to one third of patients will relapse.

High-potency topical corticosteroids and intralesional corticosteroids may be useful as monotherapy for patients with limited or mild disease or as adjuvant treatment.

Second-Line Therapies

• Potassium iodide	C
• Colchicine	C
• Indometacin	C
• Pulse intravenous corticosteroids	D
• Dapsone	D
• Clofazimine	D
• Doxycycline	E
• Metronidazole	E

Potassium iodide in dermatology: a 19th century drug for the 21st century - uses, pharmacology, adverse effects, and contraindications

Sterling JB, Heymann WR. J Am Acad Dermatol 2000; 43: 691–7.

The usual dosage of potassium iodide is 40 to 60 mg orally three times a day up to 300 mg three times a day. A supersaturated solution of potassium iodide (SSKI) may also be used. Start at 3 drops orally

three times daily and increase by 1 drop per dose up to 10 drops (500 mg) three times daily until clear, then taper. SSKI is contraindicated in pregnancy, in hyperkalemia, and in patients with renal disease. Baseline thyroid function tests and periodic monitoring are required for patients on SSKI.

Long-term suppression of chronic Sweet's syndrome with colchicine

Ritter S, George R, Serwatka LM, Elston DM. J Am Acad Dermatol 2002; 47: 323–4.

A case report of successful long-term treatment using 0.6 mg colchicine twice daily.

Indomethacin treatment of eighteen patients with Sweet's syndrome

Jeanfils S, Joly P, Young P, Le Corvaisier-Pieto C, Thomine E, Lauret P. J Am Acad Dermatol 1997; 36: 436–9.

A prospective open-label, uncontrolled study of 18 patients treated with indometacin 150 mg daily for 7 days, followed by 100 mg daily from days 7 to 21. Seventeen of 18 patients responded within 48 hours, and no relapses occurred.

Association of acute neutrophilic dermatosis and myelodysplastic syndrome with (6;9) chromosome translocation: a case report and review of the literature

Megarbane B, Bodemer C, Valensi F, Radford-Weiss I, Fraitag S, MacIntyre E, et al. Br J Dermatol 2000; 143: 1322–4.

Pulse corticosteroid therapy was successful for refractory and/or recurrent Sweet syndrome. Intravenous methylprednisolone up to 1000 mg daily for 3 to 5 days was used, followed by a low-dose taper of an oral corticosteroid with or without another immunosuppressant.

Treatment of giant cellulitis-like Sweet syndrome with dapsone

Koketsu H, Ricotti C, Kerdel FA. JAMA Dermatol 2014; 150: 457–9.

A case report of a patient with giant inflammatory Sweet syndrome lesions treated with dapsone 100 mg daily, allowing for complete resolution of symptoms.

Sulfapyridine may be used as an alternative to dapsone in doses from 1 to 4 g per day.

Sweet's syndrome in association with generalized granuloma annulare in a patient with previous breast cancer

Anthony F, Holden CA. Clin Exp Dermatol 2001; 26: 668–70.

A report of Sweet syndrome successfully treated with clofazimine.

Clofazimine 200 mg daily for 4 weeks followed by 100 mg daily for 4 weeks has been reported to be an effective dosage regimen in six patients.

Successful treatment of Sweet's syndrome with doxycycline

Joshi RK, Atukorala DN, Abanmi A, Al Khamis O, Haleem A. Br J Dermatol 1993; 128: 584–6.

Two patients with Sweet syndrome reported resolution of skin lesions after treatment with 100 mg doxycycline twice daily.

Sweet's syndrome in association with Crohn's disease: report of a case and review of the literature

Rappaport A, Shaked M, Landau M, Dolev E. Dis Colon Rectum 2001; 44: 1526–9.

A patient successfully treated with metronidazole and prednisone.

Third-Line Therapies

• Ciclosporin	E
• Interferon	E
• Cyclophosphamide	E
• Chlorambucil	E
• Etretinate	E
• Etanercept	E
• Thalidomide	E
• Anakinra	E
• Intravenous immunoglobulin (IVIG)	E
• Sulfapyridine	E
• Azathioprine	E
• Azacitidine	E
• Lenalidomide	E
• Rituximab	E

Peripheral ulcerative keratitis: an extracutaneous neutrophilic disorder. Report of a patient with rheumatoid arthritis, pustular vasculitis, pyoderma gangrenosum, and Sweet's syndrome with an excellent response to cyclosporine therapy

Wilson DM, John GR, Callen JP. J Am Acad Dermatol 1999; 40: 331–4.

One patient with Sweet syndrome responded to ciclosporin.

Initial doses of 2 to 10 mg/kg daily have been used successfully and should generally be limited to short-term use given its potential renal toxicity when used chronically.

Systemic interferon-alpha treatment for idiopathic Sweet's syndrome

Bianchi L, Masi M, Hagman JH, Piemonte P, Orlandi A. Clin Exp Dermatol 1999; 24: 443–5.

One patient responded to interferon- α 3 million units intramuscularly three times weekly plus hydroxyurea 500 mg twice daily for 30 days, tapered to 500 mg daily for an additional 30 days. The patient maintained remission for 2 years with intramuscular interferon- α as monotherapy.

Cyclophosphamide therapy in Sweet's syndrome complicating refractory Crohn's disease: efficacy and mechanism of action

Meinhardt C, Buning J, Fellermann K, Lehnert H, Schmidt KJ. J Crohns Colitis 2011; 5: 633–7.

Cyclophosphamide pulse therapy at a dose of 15 mg/kg in a patient with Crohn-associated Sweet syndrome yielded rapid response with significant relief of clinical symptoms. Thereafter, treatment was given three times at 4-week intervals.

Etanercept treatment in Sweet's syndrome with inflammatory arthritis

Ambrose NL, Tobin AM, Howard D. J Rheumatol 2009; 36: 6.

A patient with concurrent inflammatory arthritis experienced remarkable improvement upon treatment with etanercept 50 mg/week subcutaneously.

Thalidomide in the treatment of recalcitrant Sweet's syndrome associated with myelodysplasia

Browning C, Dixon J, Malone J, Callen J. J Am Acad Dermatol 2005; 53: S135–8.

A patient cleared completely with thalidomide 100 mg daily.

The use of pulse methylprednisolone and chlorambucil in the treatment of Sweet's syndrome

Case JD, Smith SZ, Callen JP. Cutis 1989; 44: 125–9.

Chronic and relapsing Sweet syndrome successfully treated with pulsed intravenous methylprednisolone. Remission was maintained with oral chlorambucil 4 mg daily.

Efficacy of antiinterleukin-1 receptor antagonist anakinra

(Kineret) in a case of refractory Sweet's syndrome

Kluger N, Gil-Bistes D, Guillot B, Bessis D. *Dermatology* 2011; 222: 123–7.

One of three case reports of Sweet syndrome refractory to multiple medications with a rapid and sustained response to anakinra 100 mg/day as monotherapy.

Favorable outcome of severe, extensive granulocyte colony-stimulating factor-induced, corticosteroid-resistant Sweet's syndrome treated with high-dose intravenous immunoglobulin

Calixto R, Menezes Y, Ostronoff M, Sucupira A, Botelho LF, Florencio R, et al. *J Clin Oncol* 2014; 32: e1–2.

A case report of granulocyte colony-stimulating factor (G-CSF)–induced Sweet syndrome in a patient with underlying multiple myeloma that did not resolve upon discontinuation of G-CSF or institution of steroids. The patient responded to IVIG within hours. A 2-day course of IVIG 1 g/kg per day led to complete resolution of skin lesions in 7 days.

Histiocytoid Sweet syndrome treated with azathioprine: a case report

Miller J, Lee N, Sami N. *Dermatol Online J* 2015; 21: 13.

A patient treated with 50 mg of azathioprine daily reported excellent control of cutaneous and systemic symptoms. Studies describe the potential of azathioprine to induce Sweet syndrome and other neutrophilic dermatoses, and thus, this therapy may be beneficial exclusively in this rare variant.

Complete remission of Sweet's syndrome after azacytidine treatment for concomitant myelodysplastic syndrome

Martinelli S, Rigolin GM, Leo G, Gafa R, Lista E, Cibien F, et al. *Int J Hematol* 2014; 99: 663–7.

A patient successfully treated with subcutaneous azacitidine (75 mg/m²/day). Medication was administered for 5 days, followed by a 2-day intermission, and an additional 2-day course of treatment. Multiple reports also describe the drug's tendency to induce Sweet syndrome.

Lenalidomide as a steroid sparing agent in a myelodysplastic syndrome patient with refractory Sweet syndrome

Chaulagain CP, Miller KB. Int J Blood Res Disord 2014; 1: 1–3.

A patient with Sweet syndrome and concurrent myelodysplastic syndrome reported resolution of cutaneous lesions with 5 mg lenalidomide three times weekly. On the contrary, there are a few reports indicating the drug's association with Sweet syndrome.

Rituximab for refractory subcutaneous Sweet's syndrome in chronic lymphocytic leukemia: a case report

Hashemi SM, Fazeli SA, Vahedi A, Golabchifard R. Mol Clin Oncol 2016; 4: 436–40.

A case report of a patient with chronic lymphocytic leukemia treated for refractory Sweet syndrome with rituximab (375 mg/m² body surface).

Syphilis

Eavan G. Muldoon, and Derek Freedman

Syphilis is an ancient disease that many mistakenly believe to be on the decline. Caused by the spirochete *Treponema pallidum*, syphilis is an indicator disease for human immunodeficiency virus (HIV). A syphilis diagnosis provides opportunities for screening and early diagnosis of HIV, which will have a significant impact on patients' prognosis and further infection transmission. *T. pallidum* facilitates the transmission of HIV by increasing viral load, disrupting the mucous membrane barrier, and increasing HIV shedding. Prompt recognition and treatment of syphilis have significant public and personal health

benefits, particularly for “risk takers,” who are afforded an opportunity to make lifestyle choices.

Men who have sex with men (MSM), commercial sex workers, or patients from areas with a high prevalence of syphilis have a higher risk of syphilis acquisition. A thorough history is essential and may uncover past potential risks that may not be immediately evident, such as woman with past partners who are MSM. However, most are unaware of their risk status, and routine testing is always required.

Transmission of syphilis is by direct contact with an infectious individual. Sexual contact is the most common mode of transmission. However, in the current era of so-called *safer sex practices* transmission by close contact with an active lesion, such as oral sex, biting, and even kissing, has become more common. Transplacental transmission, blood transfusion, or accidental inoculation can also rarely occur.

Management Strategy

The appropriate management is determined by the stage of syphilis infection. Infection is divided into:

- Incubation period
- Primary syphilis characterized by a primary sore or chancre(s)
- Secondary syphilis
- A period of subclinical infection or latent syphilis
- Tertiary syphilis, which does not occur in every patient

The patient is most infectious in the early stages of disease, particularly when the primary chancre, mucous patch, or condyloma lata are present. An immunologically intact person cannot spread syphilis after 4 years of infection.

Incubation Period

T. pallidum penetrates the intact mucous membrane or gains access through abraded skin. Within hours to days it enters the lymphatic system and/or bloodstream and disseminates throughout the body. This occurs soon after contact; patients have been infected by blood transfusions from donors with negative serology who are in the incubation period. The incubation period is directly proportional to

the size of the inoculum. The median incubation period is 3 weeks, but can vary from 3 to 90 days.

Primary Syphilis

Classically, a primary chancre is described as a single painless papule that occurs at the site of inoculation. This is not limited to the genital region. Any area where contact with an infectious lesion has occurred can be involved. The mouth and anal area are common extragenital sites.

The chancre appears after the incubation period, erodes, ulcerates, and becomes indurated with a cellular infiltration—this is a reflection of the immune response. The base is usually smooth, and the borders are raised and firm with a cartilaginous consistency. It is painless and has a clean appearance with no exudate unless it is superinfected. Regional lymphadenopathy with moderately enlarged, firm, nonsuppurative, and painless lymph nodes frequently accompanies the primary lesion.

The differential diagnosis of a primary chancre is *Herpes simplex*, chancroid, and traumatic superinfected lesions. Other diagnoses that should be considered are early warts caused by human papilloma virus, granuloma inguinale, tuberculosis, or atypical mycobacterial infections. Perianal lesions may be dismissed as hemorrhoids. The area should always be visualized and examined.

Secondary Syphilis

Secondary syphilis is when the spirochete multiplies and disseminates throughout the body. It lasts until a sufficient host response develops to control the organism. It begins 2 to 8 weeks after the appearance of the chancre; however, this is highly variable and the signs of primary and secondary infection may overlap. Many patients presenting with secondary syphilis do not recall a primary chancre. The manifestations of secondary syphilis are protean and varied.

Dermatologic manifestations are the most commonly recognized signs of secondary syphilis. The rash of secondary syphilis may be macular, maculopapular, papular, pustular, or a combination of these and is generally nonpruritic. Vesicular lesions occur only in congenital syphilis. Skin lesions usually begin on the trunk and

proximal extremities. Classically, they are pink-red macular lesions 3 to 10 mm in diameter. Any surface area can become involved. The rash can last from a few days up to 8 weeks. The lesions may evolve into papules and in some patients into pustules, known as *pustular syphilids*. All types of rash may be present at the same time, and the rash can involve any body surface. Palmar and plantar rashes are highly suggestive of syphilis. Fever can accompany the rash, and the clinical syndrome can be mistaken for acute HIV infection, infectious mononucleosis, or a nonspecific viral syndrome.

Alopecia occurs with hair follicle involvement. In warm, moist areas, such as the genital and perianal areas, inner aspects of the thighs, the skin under breasts, nasolabial folds, axillae, antecubital fossae, and webs of fingers and toes, the papules can coalesce and erode, resulting in painless, broad, gray-white, highly infectious plaques called *condylomata lata*. They can be easily mistaken for warts or hemorrhoids. Lesions may also develop on mucous membranes—so-called *mucous patches*. Enlargement of the epitrochlear lymph nodes is a unique finding that should always suggest the diagnosis of syphilis.

Neurologic Syphilis

Neurosyphilis—that is, syphilitic infection of the central nervous system—can present at any time after infection. It can be classified into early and late disease. Early neurosyphilis will involve the cerebrospinal fluid (CSF), meninges, and vasculature, whereas later tertiary disease syphilis tends to affect the brain parenchyma and spinal cord. Currently neurosyphilis is most commonly seen in patients with HIV infection, and these patients often present with eye disease. An unsuspecting ophthalmologist may be the first physician to encounter the patient with ocular syphilis. Ocular involvement varies with the most common presentation being uveitis. Any unexpected ocular condition, particularly in a man, should prompt the thought of ocular syphilis, which should be ruled out by serology. Auditory syphilis is less common, but should not be forgotten.

Latent Syphilis

Latent syphilis is the asymptomatic period after infection. It is usually divided into early latent disease, within 2 years of infection, and late

latent disease, after 2 years of infection. Careful history is required to attempt to stage asymptomatic disease. Sexual history, obstetric history, and travel history will all offer valuable clues, but are frequently elusive.

Tertiary Syphilis

Progression to tertiary syphilis is only seen in approximately 25% of untreated patients. It takes the form of neurologic disease, cardiovascular disease, and gummatous disease. It is rarely seen today due to antibiotic therapy; however, it may be more prevalent in certain immigrant populations.

Diagnostics and Treatment

The diagnosis of syphilis depends on the stage of the disease. *T. pallidum* is too slender to be visualized by direct microscopy, and the bacterium cannot be cultured. Dark-field or dark-ground microscopy, a specialized technique that utilizes an oblique light to visualize the organism, is classically used in cases when patients have demonstrable clinical lesions; it has a sensitivity of 50% in experienced hands. Moist lesions containing large numbers of treponemes, such as primary chancres, condyloma lata, or mucous patches, are particularly amenable to dark-field microscopy. It is not recommended for oral lesions, as commensal oral spirochetes are indistinguishable from *T. pallidum*. Although no *T. pallidum* detection tests are commercially available, some laboratories provide locally developed and validated polymerase chain reaction (PCR) tests for the detection of *T. pallidum* DNA. These provide a more sensitive tool and will identify *T. pallidum* from oral lesions. The vast majority of cases of syphilis are diagnosed by serology, an indirect diagnostic method.

Serologic tests fall into two categories: nontreponemal tests and treponemal tests. Nontreponemal tests such as rapid plasma reagin (RPR) or venereal disease research laboratory (VDRL) tests have traditionally been used for screening and may still be used in resource-limited settings. Automated enzyme immunoassay (EIA) is now recommended for screening before nontreponemal and treponemal tests. Positive tests are then confirmed with a treponemal test such as *Treponema pallidum* particle agglutination (TPPA) or

fluorescent treponemal antibody absorbed (FTA-ABS). False-positive reactions may be seen with the nontreponemal tests in autoimmune conditions and various other infections, including HIV. Quantitative nontreponemal tests are useful for providing a baseline from which change can be measured. Reinfection can be demonstrated by a fourfold rise in titer, for example. The reactivity of the test can differ depending on variation in antigen preparation, and for this reason it is recommended that sequential tests be performed using the same laboratory method and preferably performed by the same laboratory. If the clinical suspicion for syphilis is high and the nontreponemal tests are negative, a “prozone” phenomenon caused by very high antibody titers should be considered. Dilution of the serum unmasks the test to positive.

Guidelines on treatment differ; however, the basic principles are the same. *Long-acting penicillin* is the treatment of choice in all patients. Patients with neurologic or ocular involvement will need daily treatment for a minimum of 10 to 14 days with parenteral penicillin. For those allergic to penicillin, *doxycycline* is an alternative to penicillin; but in the case of neurologic disease and pregnant patients, penicillin desensitization is preferred. Patients need to be followed with regular serology after treatment to ensure adequate response to therapy.

The Jarisch–Herxheimer reaction may occur within hours of treatment, manifested by fever, chills, headache, myalgias, exacerbation of skin lesions, and other systemic symptoms. Treatment with nonsteroidal antiinflammatory agents or, in more severe cases, systemic steroids may be necessary.

Syphilis is an easily treatable disease with diverse manifestations. It is an indicator disease for HIV; consequently, all patients diagnosed with syphilis must be screened for HIV and all other sexually transmitted infections. Careful history taking regarding risks factors for the acquisition of the infection, possible chancrous lesions, systemic illness, and rash may offer vital clues in making the diagnosis of this curable disease, but routine serologic testing of all patients is a mandatory safeguard to avoid missing the diagnosis.

Tracing and management of sex partners forms part of the management of patients with syphilis. Sexual transmission is thought to be limited to the time when mucocutaneous lesions are present and is unusual after the first year of infection. Persons who have had sexual contact within 90 days with a person who has primary,

secondary, or early latent syphilis should be treated presumptively. Long-term partners should be evaluated in all cases. In areas of high endemicity, partners of late latent patients with a high nontreponemal titer (RPR >1:32) may also be treated presumptively, as these titers may be indicative of reinfection.

Referral to a genitourinary or infectious disease consultant is often appropriate

Specific Investigations

- Dark-field microscopy for primary chancre
- Enzyme immunoassay
- VDRL or RPR + FTA-ABS or TPPA
- PCR (not routinely used)
- HIV
- Sexually transmitted infection screen

Sexually transmitted diseases treatment guidelines, 2015

Workowski KA, Bolan G, Centers for Disease Control and Prevention (CDC). MMWR Recomm Rep 2015; 64: 1–137.

The definitive diagnostic test is dark-field microscopy; however, this is obviously limited to those patients who have a lesion amenable to dark-field microscopy, such as a genital lesion. Most diagnoses are made using serologic methods. An alternative is PCR; however, there are no commercial tests, and availability of PCR will depend on the individual laboratory. The combination of a nontreponemal test (e.g., VDRL or RPR) and a treponemal test (e.g., FTA-ABS or TPPA) should be used to confirm the diagnosis. Nontreponemal antibody titers correlate with disease activity: a fourfold rise in titer is necessary to demonstrate a clinically significant difference. Tests should be performed using the same method and preferably the same laboratory. VDRL and RPR are equally valid assays; however, quantitative results from the two tests cannot be compared directly. Nontreponemal titers should decline after treatment and may become nonreactive with time, particularly in patients treated for primary syphilis. Follow-up serology should be performed at 6 and 12 months after treatment. All patients diagnosed with syphilis should have a HIV test and a full sexually transmitted infection (STI) screen.

If the patient has clinical signs of neurosyphilis (e.g., cranial nerve

dysfunction, meningitis, stroke, altered mental status, loss of vibration sensation, or hearing or visual changes), further investigation with lumbar puncture and treatment is warranted.

Direct comparison of the traditional and reverse syphilis screening algorithms in a population with a low prevalence of syphilis

Binnicker MJ, Jespersen DJ, Rollins LO. J Clin Microbiol 2012; 50: 148–50.

Traditionally, serum for syphilis serology was screened by use of a nontreponemal test such as the RPR and positives confirmed with a treponemal test. However, more recently laboratories have been using automated treponemal tests such as an EIA to deal with the large volumes of samples that need to be screened. Direct comparison of this method indicates that it will pick up more false positives by EIA (0.6%); however, additional cases are also likely to be detected.

High annual syphilis testing rates among gay men in Australia, but insufficient retesting

Guy R, Wand H, Holt M, Mao L, Wilson DP, Bourne C, et al. Sex Transm Dis 2012; 39: 268–75.

Testing for syphilis is now recommended every 3 months in HIV-positive MSM and every 6 months for MSM not infected with HIV. In this survey of 6329 MSM, 14% had never tested for syphilis. Risks for not having tested were older age, lower number of sexual partners, and not being aware that syphilis may be asymptomatic. In men that were deemed high risk, not living in a metropolitan area and not being aware that syphilis could be spread through oral sex were additional risks.

First-Line Therapies

• Benzathine penicillin	A
• Procaine plus probenecid	A

Sexually transmitted diseases treatment guidelines, 2015

Workowski KA, Bolan G, Centers for Disease Control and Prevention (CDC). MMWR Recomm Rep 2015; 64: 1–137.

UK national guidelines on the management of syphilis 2015

Kingston M, French P, Higgins S, McQuillan O, Sukthankar A, Stott C, et al. Int J STD AIDS 2016; 27: 421–46.

Penicillin is the first-line therapy recommended in international guidelines for all stages of syphilis infection. Penicillin desensitization is recommended for pregnant patients or those diagnosed with neurosyphilis who have a penicillin allergy.

T. pallidum penicillin resistance has never been reported, despite >60 years of use.

Relapse of secondary syphilis after benzathine penicillin G: molecular analysis

Myint M, Bashiri H, Harrington RD, Marra CM. Sex Transm Dis 2004; 31: 196–9.

Relapse of infectious syphilis after treatment with the recommended dose of penicillin is rare, but does occur. For this reason, it is important to follow treated patients both clinically and serologically. These patients respond to higher and more prolonged doses of penicillin.

Second-Line Therapy

• Doxycycline	B
• Tetracycline	B
• Amoxicillin plus probenecid	B
• Ceftriaxone	B

All patients not receiving penicillin require close follow-up to

ensure response to therapy. Pregnant patients and patients diagnosed with neurosyphilis should be treated with penicillin and desensitized if they report a penicillin allergy.

Management of adult syphilis

Ghanem KG, Workowski KA. Clin Infect Dis 2011; 53: S110–28.

The data for using alternative agents for the treatment of neurosyphilis are limited. There are two retrospective trials looking at doxycycline in early disease; however, no patients with late syphilis infection were included, and there were few HIV-positive patients. Careful follow-up of HIV-positive patients to ensure serologic response is essential if these agents are used.

Ceftriaxone therapy for syphilis: report from the emerging infections network

Augenbraun M, Workowski K. Clin Infect Dis 1999; 29: 1337–8.

A single injection of 1 g ceftriaxone is not effective for treating infectious syphilis. Daily or alternate-day injections for 8 to 10 days appear to be efficacious, but more data are needed to evaluate late failures.

Response of HIV-infected patients with syphilis to therapy with penicillin or intravenous ceftriaxone

Spornraft-Ragaller P, Abraham S, Lueck C, Meurer M. Eur J Med Res 2011; 16: 47–51.

In a retrospective study, 24 consecutive HIV-positive patients with early syphilis infection treated with either benzathine penicillin or ceftriaxone were compared. After 20 months of follow-up, 23 of 24 patients had a serologic response to therapy, suggesting that ceftriaxone may have comparable efficacy in HIV-positive patients with higher CD4 counts.

Third-Line Therapies

• Azithromycin	C
• Erythromycin	C

Azithromycin should not be used for the treatment of pregnant patients or MSM due to high rates of resistance.

Macrolide resistance in *Treponema pallidum* in the United States and Ireland

Lukehart SA, Godornes C, Molini BJ, Sonnett P, Hopkins S, Mulcahy F, et al. N Engl J Med 2004; 351: 154–8.

A mutation that makes *T. pallidum* resistant to azithromycin was identified with the use of a restriction-digestion assay in 15 of 17 samples (88%) from Dublin, 12 of 55 samples (22%) from San Francisco, 3 of 23 samples (13%) from Seattle, and 2 of 19 samples (11%) from Baltimore. The study suggests that a mutated strain was either introduced into a sexual network or has been selected for among persons who engage in high-risk behavior.

Azithromycin resistance in *Treponema pallidum*

Katz KA, Klausner JD. Curr Opin Infect Dis 2008; 21: 83–91.

Azithromycin resistance in *T. pallidum* is increasing in the United States, Canada, and Ireland. Closer observation for treatment failures is needed in patients treated with azithromycin.

Macrolide resistance in *Treponema pallidum* correlates with 23S rDNA mutations in recently isolated clinical strains

Molini BJ, Tantalo LC, Sahi SK, Rodriguez VI, Brandt SL, Fernandez MC, et al. Sex Transm Dis 2016; 43: 579–83.

In a rabbit model, using clinical isolates with the 23S rDNA mutations, azithromycin uniformly failed to cure the infection; benzathine penicillin was effective.

Stages of Syphilis Infection

Syringomata

James A.A. Langtry

Syringomata are benign appendageal tumors of the intraepidermal eccrine sweat duct that have a characteristic histologic appearance. The typical clinical presentation is of individual skin- or tan-colored papules, with a rounded or flat surface, 1 to 5 mm in diameter. Single tumors can occur, but more commonly they are multiple and symmetric, more common in females, and from adolescence onward. Syringomata most often involve the lower eyelids, although they may

occur at other sites, including the cheeks, axillae, abdomen, and vulva. A linear distribution, familial occurrence, a variant associated with Down syndrome, and generalized forms have all been described. Frequent onset around puberty and reports of symptoms during pregnancy or menstruation have led to immunohistochemical studies of estrogen and progesterone receptors, with varying results and uncertain relevance.

Management Strategy

Syringomata of the eyelids and cheeks are in a prominent site and may appear conspicuous, and treatment may be sought to improve appearance. The syringomata are situated in the upper to mid-dermis. Available treatments aim to remove or flatten the papule produced by each syringoma. The majority of treatments are ablative in nature. Some patients may be troubled by only a few individual lesions, whereby *excision* of these is an option. Ablative modalities include scissor excision with secondary-intention healing, surgical excision of the entire cosmetic unit of the lower eyelids in patients who would also benefit from lower eyelid blepharoplasty, *electrocautery*, *electrodesiccation*, *intralesional electrodesiccation*, *dermabrasion*, *cryotherapy*, ablation with CO₂ or *erbium:YAG laser*, and *radiofrequency* ablation.

Local anesthesia is needed before treatment, and this may be topical or by local injections, with or without nerve blocks. Local anesthetic injections producing a field block are most commonly employed, as good anesthesia is helpful when using ablative treatments near the eye. Patients should be warned about the possibility of postoperative bruising. Eye protection is of paramount importance, and specific precautions relevant to the use of lasers must be taken if laser treatment is used.

Ablative treatments will produce some degree of scarring and the aim is to make this imperceptible and produce an excellent cosmetic result. Possible sequelae, including scarring and hypo- or hyperpigmentation (especially with increasing skin pigmentation), should always be discussed before treatment.

There are no studies comparing different treatment modalities for syringomata and a dearth of long-term follow-up data on which to base recommendations for treatment. On the basis of experience and

the limited evidence available, it is not necessary to have the latest and most expensive technology to achieve good results. Expertise and good outcomes with simple, “low-tech” methods are as important as with “high-tech” modalities. Each has benefits as well as pitfalls for the novice or unwary. It is more important to be expert in the use and application of one or more modalities than to “have a go” at them all.

Specific Investigations

The clinical features of periorbital syringomata are usually diagnostic, and a skin biopsy may be undertaken for confirmation or when there is uncertainty.

First-Line Therapies

• Surgical excision	E
• Snip excision and secondary intention healing	E
• Electrocautery	E
• Intralesional electrodesiccation	D
• CO ₂ laser	D

Cosmetic dermatologic surgery, 2nd edn

Stegman SS, Tromovitch TA, Glogau RG, eds. Chicago: Year Book Medical, 1992; 32.

A commonsense approach to treatment of syringomata, advocating the use of surgical excision, electrosurgery, or laser.

An easy method for removal of syringoma

Maloney ME. J Dermatol Surg Oncol 1982; 8: 973–5.

A single case is reported with a good outcome after removal of four to six lesions per session in 12 sessions over 5 months.

A good photographic demonstration of the removal of periorbital syringomata with fine ophthalmic spring-action scissors.

True electrocautery in the treatment of syringomas and other benign cutaneous lesions

Langtry JAA, Carruthers JA. *J Cutan Med Surg* 1997; 2: 60–3.

The technique of electrocautery is described and good results reported in a number of benign skin lesions, including syringomata.

Intralesional electrodesiccation of syringomas

Karma P, Benedetto AV. *Dermatol Surg* 1997; 23: 921–4.

Twelve patients were treated with electrodesiccation via a fine electrode into the center of the syringoma with the aim of localizing the effect and minimizing scarring. All reported excellent results and no recurrence after a follow-up of 18 to 48 months. Two patients with Fitzpatrick skin type IV had focal hyperpigmentation, which cleared in 2 to 3 months.

Syringomas treated by intralesional insulated needles without epidermal damage

Hong S-W, Lee H-J, Cho S-H, Soe J-K, Lee D, Sung H-S. *Ann Dermatol* 2010; 22: 367–96.

Favorable outcome reported in two patients treated by intralesional electrosurgery with insulated needles.

Treatment of multiple facial syringomas with the carbon dioxide (CO₂) laser

Wang JJ, Roenigk Jr HH. *Dermatol Surg* 1999; 25: 136–9.

A description of 10 patients treated with CO₂ laser reporting excellent results. Patients with more lesions needed more treatment sessions. The median follow-up was 16 months, and one patient had new syringomata at other periorbital sites 18 months after treatment. Erythema lasted 6 to 12 weeks in all patients. One patient with Fitzpatrick type IV skin had minimal focal areas of hyperpigmentation, which cleared after 2 to 3 months.

Treatment of syringoma using an ablative 10,600-nm carbon dioxide fractional laser

Cho SB, Kim HJ, Lee SJ, Kim YK, Lee JH. *Dermatol Surg* 2011; 37: 433–8.

Thirty-five patients with periorbital syringomata were treated with two sessions of fractional CO₂ laser at 10-month intervals. At 2

months' follow-up clinical improvement (pretreatment and posttreatment clinical photographs and patient satisfaction rates) was total in 9%, marked in 43%, moderate in 34%, and minimal in 14%.

Periorbital syringoma treated with radiofrequency and carbon dioxide (CO₂) laser in five patients

Hasson A, Farias MM, Nicklas C, Navarrete C. J Drugs Dermatol 2012; 11: 879–80.

Good cosmetic results reported in five patients with periorbital syringomata treated with the combination of radiofrequency and CO₂ laser.

Second-Line Therapies

• Electrodesiccation and curettage	E
• Cryotherapy	E
• Combination of CO ₂ laser and trichloroacetic acid	D

Syringoma: removal by electrodesiccation and curettage

Stevenson TR, Swanson SA. Am Plast Surg 1985; 15: 151–4.

The technique is described and well illustrated. Good results are reported, but there is no description of numbers of patients treated, clinical details, or follow-up data using this technique.

Cryosurgery

Dawber RPR. In: Lask GP, Moy RL, eds. Principles and Techniques of Cutaneous Surgery. New York: McGraw-Hill, 1996; 154.

Syringoma is listed as a condition treatable by cryotherapy.

Details are not given, and periorbital syringomata are not specifically mentioned.

A new treatment for syringoma. Combination of carbon dioxide laser and trichloroacetic acid

Kang H, Kim NS, Kim YB, Shim WC. Dermatol Surg 1998; 24: 1370–4.

This study evaluates the histopathology and efficacy of combined

CO₂ laser and 50% trichloroacetic acid treatment in 20 Korean patients with periorbital syringomata. Results were reported as excellent (11 patients), good (6), and fair (3), without complications such as scarring, infection, or textural change, using the technique detailed.

Erbium YAG laser treatment of periorbital syringomas by using the multiple ovoid-shape ablation method

Kitano Y. J Cosmet Laser Ther 2016; 18: 280–5.

Forty-nine patients with syringomata were treated every 2 months with an erbium:YAG laser, ablating multiple 2- to 4-mm egg-shaped fields. More than 75% of syringomata disappeared in 43 of 49 patients after an average of 3.77 treatments.

Third-Line Therapies

• Dermabrasion	E
• Trichloroacetic acid	E
• Topical atropine	E
• Topical tretinoin	E

Dermabrasion by diamond fraises revolving at 85000 revolutions per minute

Fulton JE. J Dermatol Surg Oncol 1978; 4: 777–9.

High-speed dermabrasion is described and good results are reported in 65 patients with acne scarring, actinic damage, adenoma sebaceum, and syringomata.

The treatment of eruptive syringomas in an African American patient with a combination of trichloroacetic acid and CO₂ laser

destruction

Frazier CC, Camacho AP, Cockerell CJ. *Dermatol Surg* 2001; 27: 489–92.

A single case report of eruptive facial syringomata in an African American woman treated by 35% trichloroacetic acid peel, followed 2 weeks later by CO₂ laser, with acceptable cosmetic results and without significant side effects.

Eruptive pruritic syringomas: treatment with topical atropine

Sanchez TS, Dauden E, Casas AP, Garcia-Diez A. *J Am Acad Dermatol* 2001; 44: 148–9.

A single case report of pruritic syringomata of the chest and neck improving with topical 1% atropine.

Eruptive syringoma: treatment with topical tretinoin

Gomez MI, Perez B, Azana JM, Nunez M, Ledo A. *Dermatology* 1994; 189: 105–6

A 23 year old woman with asymptomatic eruptive syringoma treated with 0.1% tretinoin cream daily for 4 months, resulting in flattening of the lesions in the areas treated.

Tinea capitis

Elisabeth M. Higgins[†]

Tinea capitis (scalp ringworm) is the term used to describe a fungal infection of the scalp caused by dermatophyte species. Infections may be passed from person to person (anthropophilic, in which man is the primary host) or acquired from animals (zoophilic). Several different species of fungi may be responsible, predominantly *Microsporum* and *Trichophyton* species, and can be identified by their varied characteristics on microscopy and culture. Species that invade only

the inside of the hair shaft are termed *endothrix infections*, whereas those that invade both the inside and the outside of the hair shaft are responsible for *ectothrix infections*. The disease is most prevalent in children and usually presents with areas of scaling and alopecia, with a varying degree of inflammation. There may be associated cervical lymphadenopathy. Some species of dermatophyte induce a very inflammatory, pustular reaction, which may lead to scarring and permanent alopecia. However, this is fortunately relatively rare with modern treatment regimens, in which full regrowth of hair is the norm.

A transient pruritic, papular dermatophytid (“id”) reaction, characteristically involving the ear, but often more widespread, may occur either before or on initiation of treatment, particularly in kerion infections, but should not be confused with a drug hypersensitivity.

Management Strategy

Treatment of tinea capitis is aimed at eradicating the organism to prevent the spread of infection and minimize scarring. Established infections cannot be treated topically, and oral therapy is required. Although *griseofulvin* remains the only licensed oral antifungal agent for use in tinea capitis in children in the UK, many countries have adopted newer treatment protocols. Although only weakly fungistatic, griseofulvin is effective in the treatment of most varieties of tinea capitis, but may need to be given in high doses over a prolonged period. Each case should be monitored to ensure adequate treatment and eradication of the organism. Traditionally this has been done using Wood light examination, but this is only viable in cases due to species that fluoresce (e.g., *Microsporum* infections). An increasing number of cases in the UK and North America today are due to the emergence of *Trichophyton tonsurans*, a nonfluorescent endothrix species. Treatment response therefore has to be followed mycologically by sending specimens to the laboratory. Mycologic cure should be the gold standard of treatment. However, evidence is emerging that dermoscopy may provide a rapid diagnostic tool for initiation of treatment.

In recent years the azoles *itraconazole*, *ketoconazole*, and *fluconazole* and the allylamine *terbinafine* have become available for systemic use. Many studies have demonstrated that these agents have at least equal efficacy to *griseofulvin* in a variety of types of tinea capitis, and

treatment times are often shorter. Although more expensive, shorter treatment regimens may help compliance and reduce the spread of infection.

Over the past decade, the use of intermittent or pulsed treatment regimens using *fluconazole* or *itraconazole* has been explored. This treatment strategy is based on the long half-life of the drugs in keratin. Such regimens do not appear to confer any benefit in terms of cure rates, but may reduce the total cost of treatment.

There are variations in the response of different dermatophyte species to the different antifungal agents, and treatment should be tailored accordingly. Overall, *griseofulvin* appears superior in the clearance of *Microsporum* infections, but newer agents appear more effective against *Trichophyton*. Itraconazole probably has the broadest spectrum of action. However, so far no agent has been shown to achieve a 100% cure rate. Ectothrix infections are generally caused by *Microsporum* species, most notably the zoophilic *M. canis* or the anthropophilic *M. audouinii*, and almost always occur in children. Historically, *griseofulvin* has been the standard treatment at a dose of 10 to 20 mg/kg/day, but clearance may be slow, and treatment should be continued for as long as necessary, which is at least 6 weeks, but may be 12 to 16 weeks, and monitored as outlined earlier. Itraconazole may be considered an alternative. Although there are licensing restrictions in some countries, it has now superseded *griseofulvin* as the treatment of choice in parts of Europe.

Endothrix infections, most commonly with *T. tonsurans* or *T. violaceum*, are more prevalent in children, but may occasionally occur in adults (usually the contacts/carers of children). Higher-dose regimens of *griseofulvin* tend to be required to achieve cure. The newer azoles and *terbinafine* appear to achieve clearance more rapidly (usually in 4 weeks). In adults with tinea capitis due to *Trichophyton* species, *terbinafine* 250 mg/day for 4 weeks is the treatment of choice. Although unlicensed in children, the current British Association of Dermatology guidelines and *British National Formulary* give the dosing schedule for *terbinafine* in children, in recognition of its widespread use in tinea capitis in this age group (<20 kg, 62.5 mg/day; 20–40 kg, 125 mg/day; >40 kg, 250 mg/day). Current evidence suggests that either this or *itraconazole* should become the treatment of choice in children with *Trichophyton* infections. Both drugs are now licensed for use in children in many countries and have replaced *griseofulvin*, which has now been withdrawn from some countries.

Topical antifungal creams and shampoos are sometimes used in conjunction with oral therapy, with the aim of reducing patient infectivity, but have no role in prophylaxis.

In the current urban epidemics of *T. tonsurans*, asymptomatic infection in household contacts is posing a significant problem in reinfection/relapse, and there is merit in screening all family members (including adults), where practical, to reduce reinfection rates.

Specific investigations

- Examination of hair and scalp scale by direct microscopy and culture
- Direct observation under Wood light for fluorescence
- Dermoscopy/trichoscopy
- Screen contacts, especially siblings, where possible

Fungal Infection: Diagnosis and Management

Richardson MD, Warnock DW. Oxford: Blackwell, 2003; 21, 87.

Scalp hairs infected by *M. audouinii*, *M. canis*, and *T. schoenleinii* fluoresce bright green under Wood light. Direct microscopic examination of hairs reveals arthrospores of the fungus either inside (endothrix) or on the outside of the hair shaft. Individual dermatophyte species can be identified by specific appearances in culture.

Trends in tinea capitis in an Irish population and a comparison of scalp brushings versus scalp scrapings as methods of investigation

Nasir S, Ralph N, O'Neill C, Cunney R, Lenane P, O'Donnell B. *Pediatr Dermatol* 2014; 31: 622–3.

A study of 391 children with tinea capitis showed hairbrush sampling was superior to scalp scrapings in confirming mycologic diagnosis, but using both methods increases the diagnostic yield ($p < 0.001$).

Screening for asymptomatic carriage of *Trichophyton tonsurans* in household contacts of patients with tinea capitis: results of 209 patients from south London

White JM, Higgins EM, Fuller LC. *J Eur Acad Dermatol Venereol*

2007; 21: 1061–4.

More than 50% of household contacts in this study had positive fungal cultures (7.1% overt infection and 44.5% silent fungal carriage). Children under 16 were most likely to be affected ($p < 0.001$), especially girls ($p < 0.01$).

Tinea capitis: predictive value of symptoms and time to cure with griseofulvin treatment

Lorch-Dauk KC, Comrov E, Blumer JL, O’Riordan MA, Furman LM. Clin Pediatr 2010; 49: 280–6.

In a prospective, nonblind intervention study of 99 children, the predictive value of any one of four cardinal signs/symptoms of tinea capitis (scalp scaling, alopecia, pruritus, lymphadenopathy) was shown to be 88%.

Treatment of tinea capitis often needs to be started before laboratory confirmation is obtained. Treatment should be started on the basis of clinical evidence, but appropriate mycology samples should always be sent before initiation of therapy.

Trichoscopy in pediatric patients with tinea capitis: a useful method to differentiate from alopecia areata

Ekiz O, Sen BB, Rifaioğlu EN, Balta I. J Eur Acad Dermatol Venereol. 2014; 28: 1255–8.

A study of 25 children (15 with tinea capitis and 10 with alopecia areata) identified distinctive features on dermoscopy of the hair and scalp in children with fungal infections, including broken, dystrophic, corkscrew, barcode, and comma hairs, as well as black dots.

The use of handheld magnification is a cheap technique and is proving increasingly valuable in confirming the diagnosis of tinea capitis and differentiating from other causes of alopecia.

Are dermatophytid reactions in patients with kerion celsi much more common than previously thought? A prospective study

Topaloğlu Demir E, Karadağ AS. Pediatr Dermatol 2015; 32: 635–40.

A prospective study identified dermatophytid reactions in 13 of 19 children (68%) being treated for kerion.

Dermatophytid reactions in children with tinea capitis are probably underrecognized and underreported.

First-Line Therapies

• Griseofulvin	A
• Terbinafine	A
• Itraconazole	A

Meta-analysis of randomized controlled studies comparing griseofulvin and terbinafine in the treatment of tinea capitis

Tey HL, Tan AS, Chan YC. J Am Acad Dermatol 2011; 64: 663–70.

A pooled analysis of seven studies, involving 2163 subjects, revealed no overall difference in efficacy between 8 weeks' (range 6–12 weeks) griseofulvin and 4 weeks' (range 2–6 weeks) terbinafine, but the latter had shorter treatment regimens (odds ratio = 1.22 in favor of terbinafine; 95% CI = 0.785–1.919; $p = 0.37$). However, subanalysis by species shows terbinafine has significantly greater efficacy against *T. tonsurans* (odds ratio = 1.49; 95% CI = 1.274–2.051; $p < 0.001$). In contrast, griseofulvin was superior in the treatment of *Microsporum* species (odds ratio in favor of griseofulvin = 0.48, 95% CI, 0.254–0.656; $p < 0.001$).

Terbinafine is superior in the treatment of T. tonsurans; griseofulvin is more effective in the treatment of Microsporum species, but the treatment course is longer. Both drugs are well tolerated in children.

Terbinafine hydrochloride oral granules versus oral griseofulvin suspension in children with tinea capitis: results of two randomised investigator-blinded, multicenter, international, controlled trials

Elewski BE, Cáceres HW, Deleon L, El Shimy S, Hunter JA, Korotkiy

N, et al. J Am Acad Dermatol 2008; 59: 41–54.

A multicenter, investigator-blinded, randomized controlled study comparing 6 weeks' treatment with griseofulvin 10 to 20 mg/kg/day ($n = 509$) with terbinafine 5 to 8 mg/kg/day ($n = 1040$) in children with microscopy-proven tinea capitis. Complete cure rates (45.1% vs. 33.01%) and mycologic cure (61.55% vs. 55.5%) were significantly higher for terbinafine than for griseofulvin ($p < 0.05$), even at higher doses (>20 mg/kg/day). Subgroup analysis revealed that terbinafine was significantly better than griseofulvin for all cure rates (clinical, mycologic, and complete) in *T. tonsurans* infection but not for *M. canis* ($p < 0.001$). In contrast, for *M. canis*, mycologic and clinical cure rates were significantly better with griseofulvin ($p < 0.05$). Fifty percent of patients in each group reported mild side effects with treatment, but there was no significant effect on liver transaminases.

This largest pediatric study to date highlights the safety and efficacy of a new formulation of terbinafine in the treatment of tinea capitis in children. However, limitations of the study included not using a standard dose of griseofulvin in each center, inconsistency in the use of adjuvant topical therapy, and the inclusion of more than one causal species. Subanalysis shows a clear differentiation in response rates between organisms, and therapy should probably be tailored, with terbinafine being the treatment of choice in T. tonsurans infection, whereas griseofulvin is superior in Microsporum infections.

Systemic antifungal therapy for tinea capitis in children

González U, Seaton T, Bergus G, Jacobson J, Martínez-Mónzon C. Cochrane Database Syst Rev 2007; 4: CD004685.

An analysis of 21 randomized control trials involving 1812 subjects under the age of 18 years, in which systemic antifungal therapy was used in mycologically proven tinea capitis. In view of varying susceptibilities, studies were evaluated according to the causal organism. For *Trichophyton* species, *terbinafine* given on a weight-related dosage schedule for 4 weeks showed similar efficacy to *griseofulvin* given for 8 weeks in three studies involving 382 subjects (RR 1.09; 95% CI, 0.95–1.26). Itraconazole and griseofulvin given for 6 weeks showed similar cure rates in a study of 35 children (RR 1.06; 95% CI, 0.81–1.39). However, *itraconazole* given for short periods may also be as effective as griseofulvin given for 6 weeks (RR 0.89; 95% CI, 0.76–1.04), and both itraconazole and terbinafine given for 2 to 3 weeks were equally effective in two studies involving 160 participants

(RR 0.93; 95% CI, 0.72–1.19). For *Microsporum* species, overall, no difference was found between the efficacy of griseofulvin and that of terbinafine in clearance of *Microsporum* infections, but there was little evidence on the use of systemic agents in this species that met the study inclusion criteria.

The authors conclude that terbinafine and itraconazole are probably preferable to griseofulvin in the treatment of Trichophyton tinea capitis because of the shorter treatment duration, even though these agents are more expensive and may not always be available in a pediatric formulation.

Tinea capitis in early infancy treated with itraconazole

Binder B, Richtig E, Weger W, Ginter-Hanselmayer G. J Eur Acad Dermatol Venereol 2009; 23: 1161–3.

In a pilot study of seven infants <1 year of age with *M. canis* tinea capitis, itraconazole was found to be effective and well tolerated.

Itraconazole has been shown to be safe in the treatment of young infants, including neonates, although study numbers were inevitably small.

Second-Line Therapies

• Fluconazole	B
• Short-duration terbinafine	B
• Short-duration itraconazole	B

Comparative evaluation of griseofulvin, terbinafine and fluconazole in the treatment of tinea capitis

Grover C, Arora P, Manchanda V. Int J Dermatol 2012; 51: 455–8.

A prospective, nonblinded, cross-sectional study of 75 children comparing griseofulvin, terbinafine, and fluconazole in the treatment of tinea capitis (predominantly *T. violaceum*) revealed cure rates of 96%, 88%, and 84%, respectively. Seven patients required more prolonged therapy, but all three drugs were well tolerated.

Although well tolerated, fluconazole had comparatively lower cure rates in this population, and therefore appears to confer no advantage over standard protocols using griseofulvin. However, some patients required prolonged treatment, and these may have been due to infections with other species, but full subanalysis by drug and organism was not undertaken due to the small numbers involved.

Once weekly fluconazole is effective in children in the treatment of tinea capitis: a prospective multicenter study

Gupta AK, Dlova N, Taborda P, Morar N, Taborda V, Lynde CW, et al. Br J Dermatol 2000; 142: 965–8.

An open, multicenter assessment of 61 children treated with oral fluconazole 8 mg/kg once weekly for 8 weeks (extended for a further 4 weeks if clinically indicated). Causal organisms were *T. violaceum* ($n = 33$), *T. tonsurans* ($n = 11$), and *M. canis* ($n = 17$). All 44 children with *Trichophyton* infections had mycologic and clinical cure at 16 weeks after the start of treatment; the majority (35/44) only required 8 weeks of therapy, but 9 out of 33 of the *T. violaceum* group required treatment for 12 weeks. Twelve out of 17 of the *M. canis* group were clinically clear after 8 weeks. Treatment was extended for a total of 12 weeks in one and 16 weeks in 3 patients, but overall 16 of 17 children in this group had complete cure 2 months after the end of therapy. One child had asymptomatic and reversible elevation of liver function tests.

Short duration treatment with terbinafine for tinea capitis caused by *Trichophyton* or *Microsporum* species

Hamm H, Schwinn A, Brautigan M, Weidinger G. Br J Dermatol 1999; 140: 480–2.

A double-blind study of 35 children comparing the efficacy of 1 or 2 weeks of oral terbinafine, 62.5 to 250 mg/day according to weight. Patients were followed up for 12 weeks, and nonresponders were given an additional 4 weeks of therapy. Twenty-three children had *Trichophyton* infections ($n = 12$ with *T. tonsurans* infection), and 12 had *M. canis* infection; cure rates after 1 and 2 weeks of therapy were 86% and 56%, respectively. However, only 1 of the 12 children with *Microsporum* infection responded initially, although a further 4 cleared with 4 more weeks of treatment.

Short-duration (2 weeks) and intermittent treatment regimens show remarkable clearance rates, particularly in infections with *Trichophyton*

species, and may offer a significant cost savings.

Third-Line Therapies

• 2% ketoconazole	B
• Selenium sulfide shampoo	B
• Prednisolone	B

A retrospective study of the management of pediatric kerion in *T. tonsurans* infection

Proudfoot LE, Higgins EM, Morris-Jones R. *Pediatr Dermatol* 2011; 78: 655–7.

A retrospective study of all children less than 10 years of age presenting with kerion infection to a single unit over a 6-year period revealed no advantage in concomitant use of oral or intralesional steroids compared with oral antifungal therapy alone.

A randomised comparative trial of treatment of kerion celsi with griseofulvin plus oral prednisolone vs. griseofulvin alone

Hussain I, Muzzafar F, Rashid T, Jahangir M, Haroon TS. *Med Mycol* 1999; 37: 97–9.

A randomized study of 30 patients with scalp kerion comparing treatment with griseofulvin and prednisolone to griseofulvin alone. Evaluation at 12 weeks revealed similar cure rates in both groups.

Although traditionally many clinicians have used prednisolone to reduce the inflammation of kerions in an effort to minimize scarring and hence the possibility of permanent alopecia, the limited evidence that exists does not support its use. Kerion formation is not uncommon in the current spate of T. tonsurans infections in the UK. However, scarring is exceptionally rare, and full regrowth of hair can be expected after appropriate oral antifungal therapy alone.

Successful treatment of tinea capitis with 2% ketoconazole

shampoo

Greer DL. Int J Dermatol 2000; 39: 302–4.

Sixteen children aged 3 to 6 years with *T. tonsurans* tinea capitis were treated with 2% ketoconazole shampoo daily for 8 weeks. All showed clinical improvement, some as early as 2 weeks. Six of 15 (40%) had negative cultures at 8 weeks, and 5 (33%) remained clear 1 year later.

Comparison of 1% and 2.5% selenium sulphide in the treatment of tinea capitis

Gibbens TG, Murray MM, Baker RC. Arch Pediatr Adolesc Med 1995; 149: 808–11.

A randomized controlled trial of 54 patients showing that selenium sulfide, as either a lotion or a shampoo, reduces surface counts of dermatophytes in children being treated with griseofulvin 15 mg/kg/day.

Prophylactic ketoconazole shampoo for tinea capitis in a high risk pediatric population

Bookstaver PB, Watson HJ, Winters SD, Carlson AL, Schulz RM. J Pediatr Pharmacol Ther 2011; 16: 199–203.

A retrospective analysis of 97 vulnerable children considered at high risk of tinea capitis showed no benefit from twice-weekly use of 2% ketoconazole shampoo in the prevention of infection.

These small studies support the use of an antifungal shampoo to reduce surface counts of the organism, and therefore aid clearance and possibly reduce the risk of transmission. If systemic therapy is contraindicated or unavailable, there may be a limited benefit in using 2% ketoconazole shampoo alone. However, shampoos have not been shown to prevent infection, even in vulnerable children, and have no place in prophylaxis.

Tinea pedis and skin dermatophytosis

Aditya K. Gupta, Kelly A. Foley, and Sarah G. Versteeg

(With permission from Tinea pedis. Busam Klaus J, ed. Dermatopathology: A Volume in the Series: Foundations in Diagnostic Pathology, 2nd edn. Philadelphia, PA: Elsevier, 2010.)

Dermatophytosis is a cutaneous fungal infection commonly caused by *Epidermophyton*, *Trichophyton*, and *Microsporum*, affecting the soles of the feet and interdigital spaces (tinea pedis), groin (tinea cruris),

face (tinea faciei), and skin (tinea corporis). Cutaneous fungal infections have a worldwide prevalence of 20% to 25%; with an increase in urbanization, communal sports, and an aging population, prevalence of dermatophyte infections may be on the rise. Additionally, due to extreme humidity and high temperatures, skin dermatophytoses frequently occur in tropical and subtropical regions.

Epidemiologic trends in skin mycoses worldwide

Havlickova B, Czailka VA, Friedrich M. *Mycoses* 2008; 51: 2–15.

This review is a summary of the geographic prevalence of skin dermatophytoses and the causative fungal organisms. In addition to already established risk factors (e.g., gender, foot trauma), an increase in public sporting events, diabetes, and travel has increased the prevalence of tinea pedis in developed countries, whereas in developing parts of the world, tinea capitis may be more abundant.

Epidemiology of dermatophytoses: retrospective analysis from 2005 to 2010 and comparison with previous data from 1975

Garofalo A, Bosco A, Cassano N. *New Microbiol* 2012; 35: 207–13.

This is a retrospective analysis of all cases of dermatophytoses (6133 patients) presenting to an Italian dermatology clinic from 2005 to 2010. Tinea corporis (22.7%) and tinea pedis (20.4%) were the most common skin dermatophytoses observed. Cases of tinea pedis showed a male predominance with trends of an increase in occurrence.

Tinea pedis: the etiology and global epidemiology of a common fungal infection

Ilkit M, Durdu M. *Crit Rev Microbiol* 2015; 41: 374–88.

Tinea pedis is commonly found in adult males (31–60 years old) with a higher prevalence in high-risk occupations (e.g., miners, soldiers, runners). Complications associated with tinea pedis include cellulitis, id reaction, and Majocchi granuloma.

Management Strategy

Topical therapies (e.g., azoles, allylamines) are the first line of defense when treating tinea pedis, localized tinea corporis, and tinea cruris. Many topical treatments do not require a prescription, and treatment

durations ranging from 2 to 4 weeks are usually sufficient for successful management of most dermatophytoses. Where infection is serious or more extensive (i.e., covers a large surface area of the body) or is recurrent, oral antifungal treatments may be needed. High mycological cure rates have been found with oral treatments such as terbinafine (75%–85%), itraconazole (79%), and fluconazole (93%). Treatments with additional antibacterial capabilities (e.g., ciclopirox olamine, miconazole nitrate, ketoconazole, etc.) can also be beneficial as bacterial superinfections can co-occur with tinea infections. Some preventative measures, including educational programs, maintaining proper hygiene, avoiding communal areas, and using antimicrobial fabrics, may help limit relapse and prevent transmission.

Management of tinea corporis, tinea cruris, and tinea pedis: a comprehensive review

Sahoo AK, Mahajan R. Indian Dermatol Online J 2016; 7: 77–86.

Topical therapies (e.g., antifungals) are effective at treating tinea infections (e.g., tinea corporis, tinea cruris, tinea faciei, tinea pedis), and nonpharmacologic management (e.g., loose-fitting socks) can help to reduce moisture. Oral therapy is suggested for extensive or nonresponsive infections.

Specific investigations

- Direct microscopy on KOH specimens
- Fungal culture

In order to successfully treat dermatophytosis, accurately diagnosing the infection is paramount, as tinea infections can mimic other lesional conditions. The two main test methods used to diagnose dermatophyte infections include direct microscopy and fungal culture. Lesional scrapings can be obtained with a blade (no. 15) or banana-shaped knife, and blisters/pustule tops can be ruptured to allow for adequate sampling.

Identifying signs of tinea pedis: a key to understanding clinical variables

Canavan TN, Elewski BE. J Drugs Dermatol 2015; 14: 42–7.

T. rubrum, *T. mentagrophytes*, and *E. floccosum* are the most common

causes of tinea pedis. Tinea pedis can be found worldwide and is endemic to Southeast Asia and Western Africa. Interdigital (e.g., macerated skin), moccasin (e.g., dry, hyperkeratotic scales), vesicular (e.g., small vesicles, erythema), and acute ulcerative (e.g., ulcers, erosions) are four clinical patterns of tinea pedis.

The sensitivity and specificity of potassium hydroxide smear and fungal culture relative to clinical assessment in the evaluation of tinea pedis: a pooled analysis

Levitt JO, Levitt BH, Akhavan A, Yanofsky H. *Dermatol Res Pract* 2010; 2010: 1–8.

Sensitivity and specificity of KOH smears and fungal culture were determined through a pooled analysis of vehicle-treated participants from five randomized, double-blind clinical studies (n = 460). KOH smears (73.3%) are more sensitive than fungal cultures (41.7%) when confirming clinical assessment (negative or positive); fungal cultures (77.7%) are more specific than KOH smears (42.5%, $p < 0.0001$ and $p < 0.0001$, respectively).

Inflammatory tinea pedis/manuum masquerading as bacterial cellulitis

Sweeney SM, Wiss K, Mallory SB. *Arch Pediatr Adolesc Med* 2002; 156: 1149–52.

Four cases of children with tinea pedis or tinea manuum initially diagnosed with bacterial cellulitis are described. Infections in children may mimic bacterial infections. KOH examination produced positive results and may help in diagnosis.

First-Line Therapies

Topical

• Clotrimazole	A
• Miconazole	A
• Luliconazole	A
• Econazole nitrate	A
• Naftifine hydrochloride	A
• Sertaconazole nitrate	A

Efficacy of topical antifungal drugs in different dermatomycoses: a systematic review with meta-analysis

Rotta I, Otuki MF, Sanches AC, Correr CJ. Rev Assoc Med Bras 2012; 58: 308–18.

A meta-analysis of 49 studies revealed allylamines to be more effective than azoles when evaluating sustained cure rates for treatment of dermatomycoses. Azoles and allylamines showed higher efficacy rates (e.g., mycological cure, sustained cure) for treatment of tinea pedis, tinea cruris, and tinea corporis compared with placebo.

Efficacy and safety of once-daily luliconazole 1% cream in patients ≥ 12 years of age with interdigital tinea pedis: a phase 3, randomized, double-blind, vehicle-controlled study

Jarratt M, Jones T, Adelglass J, Bucko A, Pollak R, Roman-Miranda A, et al. J Drugs Dermatol 2014; 13: 838–46.

A phase III, vehicle-controlled study was conducted on interdigital tinea pedis patients with daily application of luliconazole for 14 days (n = 321). Clinical cure, mycological cure, and complete clearance rates 28 days posttreatment were significantly higher with luliconazole treatment (29.2%, 62.3%, and 26.4%, respectively) compared with vehicle treatment (7.8%, 17.5%, and 1.9%,

respectively) ($p < 0.001$, $p < 0.001$, and $p < 0.001$, respectively).

Econazole nitrate foam 1% for the treatment of tinea pedis: results from two double-blind, vehicle-controlled, phase 3 clinical trials

Elewski BE, Vlahovic TC. J Drugs Dermatol 2014; 13: 803–8.

Two vehicle-controlled, 4-week, double-blind, multicenter studies were conducted with econazole nitrate (1%) for treatment of interdigital tinea pedis ($n = 505$). Complete cure and mycological cure rates were higher with econazole nitrate foam (24.3% and 67.6%, respectively) compared with vehicle (3.6% and 16.9%, respectively) ($p < 0.001$ and $p < 0.0001$, respectively).

Naftifine hydrochloride gel 2%: an effective topical treatment for moccasin-type tinea pedis

Stein Gold LF, Vlahovic T, Verma A, Olayinka B, Fleischer AB Jr. J Drugs Dermatol 2015; 14: 1138–44.

A posthoc analysis of two pooled, 6-week, double-blind, vehicle-controlled, multicenter clinical trials was conducted to evaluate naftifine hydrochloride for treatment of moccasin-type tinea pedis ($n = 380$). Complete cure, mycological cure, and treatment effectiveness were higher with naftifine gel (19.2%, 65.8%, and 51.4%, respectively) compared with vehicle (0.9%, 7.8%, and 4.4%) 4 weeks posttreatment ($p < 0.0001$, $p < 0.0001$, and $p < 0.0001$, respectively).

Sertaconazole: a review of its use in the management of superficial mycoses in dermatology and gynecology

Croxtall JD, Plosker G. Drugs 2009; 69: 339–59.

Sertaconazole 2% cream was found to be more effective compared with miconazole 2% cream for treatment of tinea pedis in a placebo-controlled trial. Mycological cure was found with once-a-day and twice-a-day sertaconazole application. This antifungal is effective in both solution and cream formation.

Second-Line Therapies

Topical

• Terbinafine 1% as cream, solution, gel, or film-forming solution	A
• Ciclopirox (hydroxypyridone)	A
• Ketoconazole	D

Comparable efficacy and safety of various topical formulations of terbinafine in tinea pedis irrespective of the treatment regimen: results of a meta-analysis

Korting HC, Kiencke P, Nelles S, Rychlik R. Am J Clin Dermatol 2007; 8: 357–64.

A meta-analysis of 19 randomized controlled trials revealed that terbinafine is three times more likely to produce clinical cure in tinea pedis patients compared with placebo. Cure rates found with terbinafine are comparable to other antifungal therapies used to treat tinea pedis. The efficacy and safety of terbinafine are not influenced by treatment formulation, duration of therapy, or frequency of application.

Ciclopirox gel in the treatment of patients with interdigital tinea pedis

Aly R, Fisher G, Katz I, Levine N, Lookingbill DP, Lowe N, et al. Int J Dermatol 2003; 42: 29–35.

Two multicenter, double-blind, vehicle-controlled, clinical trials evaluated the efficacy of ciclopirox (0.77%) to treat mild-to-moderate interdigital tinea pedis with twice-daily application for 28 days (n = 374). Treatment success (mycological cure and $\geq 75\%$ clinical improvement) was found in 60% of ciclopirox-treated participants and 19% of vehicle-treated participants. Mycological cure was found in 85% of participants treated with ciclopirox and 16% of participants treated with vehicle.

Ketoconazole 2% cream in the treatment of tinea pedis, tinea cruris, and tinea corporis

Lester M. Cutis 1995; 55: 181–3.

A large study of 232 patients were evaluated after 4 and 8 weeks of treatment with once-daily ketoconazole 2% cream. Forty-nine percent of patients had total symptom scores of absent or mild at the end of treatment, and 82% responded to the treatment.

Third-Line Therapies

Topical

• 40% urea cream	D
• Photodynamic therapy	D

Systemic

• Terbinafine	A
• Itraconazole	A
• Fluconazole	A
• Griseofulvin	A

Urea: a comprehensive review of the clinical literature

Pan M, Heinecke G, Bernardo S, Tsui C, Levitt J. Dermatol Online J 2013; 19: 20392.

Eighty-one studies met inclusion criteria, with four studies specifically evaluating urea for treatment of tinea pedis. Urea showed antibacterial properties and enhanced the efficacy of topical treatments (e.g., lanoconazole, bifonazole, ciclopirox, butenafine hydrochloride).

Photodynamic therapy in the treatment of superficial mycoses: an evidence-based evaluation

Qiao J, Li R, Ding Y, Fang H. *Mycopathologia* 2010; 170: 339–43.

An evidence-based review found seven studies that used phototherapy for treatment of superficial mycoses that met inclusion criteria. After phototherapy sessions, 80% of tinea cruris patients (n = 10) and 60% of tinea pedis patients (n = 10) were mycologically cured.

Oral treatments for fungal infections of the skin of the foot

Bell-Syer SEM, Khan SM, Torgerson DJ. *Cochrane Database Syst Rev* 2012; 10: CD003584.

Terbinafine was a more effective tinea pedis treatment than griseofulvin as evaluated across 15 selected randomized, controlled trials. No significant differences in efficacy rates were found between fluconazole and itraconazole or between terbinafine and itraconazole.

A comparison of the efficacy of oral fluconazole, 150 mg/week versus 50 mg/day, in the treatment of tinea corporis, tinea cruris, tinea pedis and cutaneous candidosis

Nozickova M, Koudelkova V, Kulikova Z, Malina L, Urbanowski S, Silny W. *Int J Dermatol* 1998; 37: 703–5.

To determine the efficacy of fluconazole, patients with dermatophytoses and cutaneous candidosis were treated for 4 to 6 weeks (n = 245). Positive clinical responses (cure and marked improvement) were found in 79% to 88% of non-pedis-infected patients and in 79% to 93% of pedis-infected patients.

Efficacy and safety of short-term itraconazole in tinea pedis: a double-blind, randomized, placebo-controlled trial

Svejgaard E, Avnstorp C, Wanscher B, Nilsson J, Heremans A. *Dermatology* 1998; 197: 368–72.

Seventy-two patients with plantar or moccasin type tinea pedis received itraconazole 200 mg twice daily or placebo for 1 week. Efficacy was evaluated after an 8-week follow-up period. Itraconazole was significantly more effective than placebo in treating tinea pedis. The success rate (clinical response and mycological cure) was 53% for itraconazole compared with 3% for placebo ($p < 0.001$), and the mycological cure rate was 56% for itraconazole compared with 8% for placebo ($p < 0.001$).

Safety and efficacy of tinea pedis and onychomycosis treatment in people with diabetes: a systematic review

Matricciani L, Talbot K, Jones S. J Foot Ankle Res 2011; 4: 26.

Continuous oral therapy (e.g., terbinafine) is the suggested treatment for patients with tinea pedis and/or toenail onychomycosis and who have been diagnosed with diabetes (type 1 or 2).

Tinea unguium

Antonella Tosti

Onychomycosis accounts for about half of all nail abnormalities and a third of all fungal infections of the skin. It affects about 10% of the general population, with figures that vary in different areas of the world. About 85% of cases of onychomycosis are due to dermatophytes, the most common being *Trichophyton rubrum*, followed by *Trichophyton interdigitale*. The prevalence of onychomycosis increases with age, and the toenails are most

frequently affected. *Tinea pedis* is associated with onychomycosis in most patients. Predisposing factors for onychomycosis include old age, diabetes, HIV infection, peripheral vascular impairment, peripheral neuropathies, podiatric abnormalities, sports activities, and traumatic nail disorders.

Management Strategy

Different clinical patterns of nail infection result from the way in which fungi colonize the nail. In distal subungual onychomycosis (DSO), the most common type, fungi reach the nail from the hyponychium and colonize the nail bed, producing onycholysis and subungual hyperkeratosis. In proximal subungual onychomycosis (PSO), fungi penetrate the nail matrix via the proximal nail fold and colonize the deep portion of the proximal nail plate, resulting in a subungual white patch located in the lunula area. In white superficial onychomycosis (WSO), fungi are localized on the nail plate surface and produce whitish, opaque, friable areas on the nail plate. The type of nail invasion depends on both the causative fungus and host susceptibility.

The goals for antifungal therapy are mycologic cure and a normal-looking nail. Clinical cure, which requires several months due to slow nail growth, can be impossible to achieve when onychomycosis is associated with traumatic nail dystrophies. Immediately after treatment with systemic agents, which usually lasts 3 months, it is common to observe a still-abnormal nail; signs of a good response are no proximal progression and a proximal area of normal-appearing nail.

Treatment of onychomycosis depends on the clinical type of the onychomycosis, the number of affected nails, and the severity of involvement. A systemic treatment with *terbinafine*, *itraconazole*, or *fluconazole* is always required in PSO and in DSO involving the lunula region. WSO and DSO limited to the distal nail can be treated with a topical agent such as *efinaconazole*, *tavaborole*, *amorolfine*, or *ciclopirox*. Combined systemic and topical treatment increases the cure rate.

In recent years, the number of patients with AIDS-related or iatrogenic immunosuppression has substantially increased, leading to the appearance of new patterns of nail invasion by fungi. There is now evidence that some clinical varieties of superficial onychomycosis (i.e., in transverse lines) may be due to fungal

invasion of the nail plate under the ventral nail fold: this substantially changes treatment options, because topical therapy does not cure these cases. New types of PSO have also been described. These include nondermatophyte PSO, usually due to *Fusarium* or *Aspergillus* species, which is typically associated with acute periungual inflammation.

Terbinafine is an allylamine with fungicidal properties. Interactions of terbinafine with other drugs are extremely rare. Adverse effects may involve gastrointestinal function and the skin. Patients with known lupus erythematosus or photosensitivity are predisposed to drug-induced or drug-exacerbated disease. Liver toxicity can occasionally occur. Terbinafine is administered at a dose of 250 mg daily; treatment duration is 6 weeks for fingernails and 12 weeks for toenails. Clinical trials have repeatedly demonstrated a higher efficacy of terbinafine compared with other antifungal treatments. A meta-analysis of 18 studies on terbinafine for onychomycosis showed a mycologic cure rate of 76%.

Terbinafine persists in the nail for at least 30 weeks after the completion of treatment and is effective also when administered as a pulse regimen at a dose of 250 mg for 1 week per month every 2 or 3 months.

Itraconazole is a synthetic triazole with fungistatic activity and a broad spectrum of action. It is approved at a daily 200-mg dose. It can also be administered as pulse therapy at a dose of 400 mg daily for 1 week a month. Treatment duration is 6 weeks for fingernails and 12 weeks for toenails. The drug should be administered with a high-fat meal and/or an acidic beverage to improve its absorption. It is now not widely prescribed due to safety profile and drug interactions. A meta-analysis of six studies on pulse itraconazole for onychomycosis showed a mycologic cure rate of 63%.

Fluconazole is a bis-triazole, broad-spectrum, fungistatic drug with high oral bioavailability that is widely utilized but not approved for this indication. It is administered as a pulse treatment, with regimens ranging from 150 to 450 mg once a week for 6 (fingernails) to 9 (toenails) months. A meta-analysis of three studies on fluconazole for onychomycosis showed a mycologic cure rate of 48%.

Posaconazole is a new azole that has been evaluated in onychomycosis, and its use is likely to be limited to second-line treatment in terbinafine-refractory infections, those with nondermatophyte mold infections, or those sensitive to or intolerant

of terbinafine. It showed a mycologic cure rate of 48%.

Topical treatment can be an option in cases of mild-to-moderate onychomycosis not involving the lunula region and white superficial onychomycosis. Two new topical antifungals, efinaconazole 10% nail solution and tavaborole 5% nail solution, have recently been approved by the Food and Drug Administration (FDA) for treatment of mild-to-moderate onychomycosis of the toenails. Efinaconazole 10% solution is a topical triazole antifungal solution with a broad spectrum of activity. It should be applied daily, and results from clinical studies indicate that 25% of patients achieve complete or almost complete cure, defined as $\leq 5\%$ affected target nail area and mycologic cure after for 48 weeks of treatment. Tavaborole is a novel, broad-spectrum, oxaborole antifungal agent with strong antifungal activity against *T. rubrum* and *T. mentagrophytes*. It should be applied daily, and results from clinical studies show that 16.6% of patients achieve almost complete cure, defined as $\leq 5\%$ affected target nail area and mycologic cure after 48 weeks of therapy

Other topical antifungals include *amorolfine* 5% nail lacquer (not approved in the United States) and *ciclopirox olamine* 8% nail lacquer. Amorolfine is applied once a week, whereas ciclopirox olamine is applied daily. The clinical efficacy of monotherapy with nail lacquers is low.

Topical antifungals combined with oral treatment may increase cure rates. Numerous new topical formulations are currently being evaluated.

A new systemic antifungal, VT-1161, a potent and selective inhibitor of fungal CYP51, showed promising results in a phase IIb clinical trial.

Surgical or chemical debridement of the thickened nail plate increases cure rate.

Photodynamic therapy after application of a solution of ALA methyl ester in aqueous cream on the nails has recently been reported to be effective in *T. rubrum* onychomycosis. Several laser devices have been marketed to treat onychomycosis, including Nd:YAG lasers and diode lasers. Evidence-based data on efficacy of these different lasers are still poor.

Poor prognostic factors of onychomycosis include areas of nail involvement $>50\%$, involvement of the lateral portion of the nail, subungual hyperkeratosis thicker than 2 mm, white/yellow or orange/brown streaks in the nail (including dermatophytoma), diffuse

nail involvement that includes the matrix, and immunosuppression.

Recurrence (relapse or reinfection) of onychomycosis is not uncommon, with reported rates ranging from 10% to 53%.

Specific Investigations

- Nail clipping microscopy
- Nail clipping culture
- Direct microscopy of 40% KOH preparations of subungual scales
- Cultures of nail scrapings in Sabouraud-agar-chloramphenicol and Sabouraud-agar-chloramphenicol + actidione media
- Histopathology of PAS-stained nail clippings
- Dermatophyte test strip
- Polymerase chain reaction (PCR)

The diagnosis of onychomycosis always requires laboratory confirmation, as differential diagnosis from psoriasis or traumatic onychodystrophy is often impossible on a clinical basis.

Fungal elements in the affected nails can be detected using KOH preparations of the nail samples or histopathology of PAS-stained nail clippings. An immunochromatography test, the Dermatophyte Test Strip, can also be used. It detects dermatophytes by visualizing mycotic antigens. PCR assays have high sensitivity, provide fast results, and are now not very expensive. They might, however, be too sensitive and produce false-positive results.

Cost-effectiveness of diagnostic tests for toenail onychomycosis: a repeated-measure, single-blinded, cross-sectional evaluation of 7 diagnostic tests

Lilly KK, Koshnick RL, Grill JP, Khalil ZM, Nelson DB, Warshaw EM. J Am Acad Dermatol 2006; 55: 620–6.

This study compared the cost effectiveness of diagnostic tests for onychomycosis. KOH and PAS were equally sensitive. Identification of the responsible fungus can, however, only be done using cultures. A negative mycologic result does not rule out onychomycosis, as direct microscopy is negative in up to 10% of cases and culture in up to 30%.

Correct sampling of nail debris is mandatory for obtaining reliable mycologic results. In the most common variety of onychomycosis, DSO, culture sensitivity improves the more proximal the location of

the sample.

Optimising the diagnostic strategy for onychomycosis from sample collection to fungal identification: evaluation of a diagnostic kit for real-time PCR

Petinataud D, Berger S, Ferdynus C, Debourgogne A, Contet-Audonneau N, Machouart M. *Mycoses* 2016; 59: 304–11.

This study evaluates a commercial real-time PCR kit on 180 nail samples, showing that the kit has high specificity and sensitivity in detecting dermatophytes, regardless of sample quality.

Clinical study of Dermatophyte Test Strip, an immunochromatographic method, to detect tinea unguium dermatophytes

Tsunemi Y, Hiruma M. *J Dermatol* 2016; 43: 1417–23.

The Dermatophyte Test Strip allows easy and fast detection of dermatophytes by visualizing mycotic antigens by immunochromatography. This test only identifies dermatophyte infections and in this study was positive in 90.5% of specimens.

A new classification system for grading the severity of onychomycosis: Onychomycosis Severity Index

Carney C, Tosti A, Daniel R, Scher R, Rich P, DeCoster J, et al. *Arch Dermatol* 2011; 147: 1277–82.

The Onychomycosis Severity Index (OSI) has recently been proposed to grade the severity of DSO. The OSI score is obtained by multiplying the score for the area of involvement (range, 0–5) by the score for the proximity of disease to the matrix (range, 1–5). Ten points are added for the presence of a longitudinal streaking or a patch (dermatophytoma) or for a subungual hyperkeratosis greater than 2 mm. Mild onychomycosis corresponds to a score of 1 to 5; moderate, 6 to 15; and severe, 16 to 35.

First-Line Therapy

• Systemic terbinafine 250 mg/day (for 6 weeks for fingernails and 12 weeks for toenails)	
---	--

Onychomycosis: diagnosis and definition of cure

Scher RK, Tavakkol A, Sigurgeirsson B, Hay RJ, Joseph WS, Tosti A, et al. J Am Acad Dermatol 2007; 56: 939–44.

This article promotes guidelines for the correct management of onychomycosis, including criteria for diagnosis of dermatophyte onychomycosis, list of poor prognostic factors, criteria for assessing cure, and risk of relapses.

Oral therapy for onychomycosis: an evidence-based review

de Sá DC, Lamas AP, Tosti A. Am J Clin Dermatol 2014; 15: 17–36.

Terbinafine 250 mg daily is the most effective oral treatment of onychomycosis.

Cost-effectiveness of confirmatory testing before treatment of onychomycosis

Mikailov A, Cohen J, Joyce C, Mostaghimi A. JAMA Dermatol 2016; 152: 276–81.

Reevaluating the need for laboratory testing in the treatment of onychomycosis. Safety and cost-effectiveness considerations

Kanzler MH. JAMA Dermatol 2016; 152: 263–4.

Liver injury from terbinafine treatment is extremely rare (1 case per 50,000–120,000 treatments), and evaluating liver enzymes before starting treatment is not cost effective.

This article also discusses that confirming diagnosis is not cost effective in the case of terbinafine, as this medication is now very inexpensive.

Second-Line Therapies

• Systemic itraconazole	A
• Systemic fluconazole	A
• Systemic posaconazole	A
• Systemic itraconazole 200 mg/day or 400 mg/day for 1 week a month (for 2 months for fingernails and 3 months for toenails). A novel 200-mg formulation of itraconazole was recently introduced in the market.	
• Systemic fluconazole 300 to 450 mg/week (for 6 months for fingernails and 9 months for toenails)	
• Systemic posaconazole	

Evidence-based optimal fluconazole dosing regimen for onychomycosis treatment

Gupta AK, Drummond-Main C, Paquet M. J Dermatolog Treat 2013; 24: 75–80.

Duration of treatment is more important than weekly fluconazole

doses for cure of toenail, and possibly fingernail, onychomycosis.

The safety of oral antifungal treatments for superficial dermatophytosis and onychomycosis: a meta-analysis

Chang CH, Young-Xu Y, Kurth T, Orav JE, Chan AK. Am J Med 2007; 120: 791–8.

Treatment discontinuation due to adverse events was 3.44% for continuous terbinafine, 2.58% for pulse itraconazole, and 5.76% for intermittent fluconazole 300 to 450 mg/week. The risk of asymptomatic elevation of serum transaminase not requiring treatment discontinuation was less than 2.0% for all treatment regimens evaluated.

Third-Line Therapy

- Photodynamic therapy (PDT)

Usefulness of photodynamic therapy in the management of onychomycosis

Robres P, Aspiroz C, Rezusta A, Gilaberte Y. Actas Dermosifiliogr 2015; 106: 795–805.

According to their own experience and review of previous studies, the authors propose a protocol of three PDT sessions, separated by an interval of 1 or 2 weeks, using methyl aminolevulinate 16% and red light. Treatment should be preceded by nail plate avulsion using 40% urea. Clinical trials are needed to optimize PDT protocols and to identify those patients who will benefit most from this treatment.

Laser therapies for onychomycosis—critical evaluation of methods and effectiveness

Francuzik W, Fritz K, Salavastru C. J Eur Acad Dermatol Venereol 2016; 30: 936–42.

The authors review the available studies on lasers in onychomycosis. The majority of studies used an Nd:YAG laser device. Methodology was not homogeneous, and data are not evidence based. Efficacy is still not determined.

Topical Therapies

• Topical amorolfine	A
• Topical ciclopirox olamine	A
• Topical efinaconazole	A
• Topical tavaborole	A

Two new topical antifungals, efinaconazole 10% nail solution and tavaborole 5% nail solution, have been recently approved by the FDA for treatment of mild-to-moderate onychomycosis of the toenails. They should be applied daily on the affected nail, periungual tissues, and hyponychium. The area of infection is in fact also reached through the subungual space. Old topical antifungals include the transungual delivery systems *amorolfine* 5% nail lacquer (not approved in the United States) and *ciclopirox olamine* 8% nail lacquer. Amorolfine is applied once a week, whereas ciclopirox olamine is applied daily.

Treatment duration is long and clinical efficacy moderate to low.

There are no data on association of new topical antifungals with oral treatment. Some data show that the association of *amorolfine* with oral terbinafine may increase cure rates. Several other new topical formulations are currently undergoing clinical trials.

Efinaconazole 10% solution in the treatment of toenail onychomycosis: two phase III multicenter, randomized, double-blind studies

Elewski BE, Rich P, Pollak R, Pariser DM, Watanabe S, Senda H, et al. J Am Acad Dermatol 2013; 68: 600–8; Erratum in: J Am Acad Dermatol 2014; 70: 399.

Efficacy of efinaconazole 10% solution was evaluated in two 52-week, prospective, multicenter, randomized, double-blind studies in patients 18 years and older (18–70 years of age) with mild-to-moderate DLSO, without dermatophytoma or lunula (matrix)

involvement. These studies enrolled 1655 subjects, who were treated for 48 weeks, with a 4-week follow-up.

Pooled data from the two studies show that at the end of study, 54.4% of subjects treated with efinaconazole 10% solution obtained mycologic cure compared with 16.9% with vehicle, and 16.5% achieved clinical cure compared with 4.4% with vehicle.

A complete or almost complete cure, defined as $\leq 5\%$ affected target nail area and mycologic cure, was achieved in 25% of patients on efinaconazole and 7.2% of patients on vehicle.

Treatment success, defined as affected target toenail area of $\leq 10\%$, was obtained in 42.6% of patients treated with efinaconazole 10% solution compared with 16.1% with vehicle.

Efficacy and safety of tavaborole topical solution, 5%, a novel boron-based antifungal agent, for the treatment of toenail onychomycosis: results from 2 randomized phase-III studies

Elewski BE, Aly R, Baldwin SL, González Soto RF, Rich P, Weisfeld M, et al. J Am Acad Dermatol 2015; 73: 62–9.

Efficacy of tavaborole 5% solution was evaluated in two 52-week prospective, multicenter, randomized, double-blind studies in patients 18 years and older (18–70 years of age) with mild-to-moderate DLSO (20%–60% nail involvement), without dermatophytoma or lunula (matrix) involvement. These studies enrolled 1198 subjects, who were treated for 48 weeks, with a 4-week follow-up.

Pooled data from the two studies show that at the end of study, 33.5% of subjects treated with tavaborole 5% solution obtained mycologic cure compared with 9.7% with vehicle, and 7.8% achieved clinical cure compared with 1% with vehicle.

A complete or almost complete cure, defined as $\leq 5\%$ affected target nail area and mycologic cure, was achieved in 16.6% of patients on tavaborole and 2.7% of patients on vehicle.

A multicenter, randomized, controlled study of the efficacy, safety and cost-effectiveness of a combination therapy with amorolfine nail lacquer and oral terbinafine compared with oral terbinafine alone for the treatment of onychomycosis with matrix involvement

Baran R, Sigurgeirsson B, de Berker D, Kaufmann R, Lecha M, Faergemann J, et al. Br J Dermatol 2007; 157: 149–57.

Two hundred and forty-nine patients were randomized to receive either a combination of amorolfine hydrochloride 5% nail lacquer once weekly for 12 months plus terbinafine 250 mg once daily for 3 months, or terbinafine alone once daily for 3 months. A significantly higher success rate was observed for patients in the combination group relative to those in the terbinafine monotherapy group at 18 months (59.2% vs. 45.0%).

Tinea versicolor (pityriasis versicolor)

Aditya K. Gupta, Elizabeth A. Cooper, and Kelly A. Foley

Pityriasis (tinea) versicolor (PV) has a worldwide distribution, though the prevalence is higher in tropical climates than in temperate ones (30%–40% vs. 1%–4%, respectively). PV is caused by the lipophilic yeast species *Malassezia*. *Malassezia* organisms are a normal part of human commensal skin flora, and PV results when they are converted from the yeast phase to a mycelial phase, which is able to infect the stratum corneum, producing the characteristic hypopigmented or hyperpigmented lesions.

Infection is associated with sebaceous gland activity; hence

infection is most often seen in adults and postpubescent adolescents and rarely in prepubescent children. An equal prevalence between the sexes has been noted. Predisposing factors include high temperature and humidity, malnutrition, the use of oral contraceptives, hyperhidrosis, genetic susceptibility, increased plasma cortisol levels, and immunodeficiency.

Initially only two species under the genus name *Pityrosporum* were described. Genetic research in the 1990s confirmed at least seven species of *Malassezia*, and more have since been discovered. The most common species contributing to PV lesions are *M. globosa* (50%–60%), *M. sympodialis* (3%–59%), *M. furfur*, and *M. slooffiae* (each 1%–10%). It is not currently known whether the clinical pattern of infection or antifungal susceptibility vary between the different infecting species.

Management Strategy

Topical treatment is the first-line therapy in most cases. *Topical azoles* formulated as gels, creams, solutions, or shampoos (ketoconazole, fluconazole, bifonazole, clotrimazole, miconazole, etc.) have demonstrated efficacy for PV. The allylamine *terbinafine* has several topical formulations (solution, cream, gel, or spray) that have been used effectively, as have formulations of the benzylamine *butenafine*. *Topical ciclopirox* provides both antifungal and antiinflammatory activity against *Malassezia*.

Systemic antifungal therapies may be warranted in severe cases or cases with widespread body involvement, patients with recurrent disease, or those who are immunocompromised. Patients may also prefer a short-duration oral therapy to frequent application of a topical agent.

Second-line therapy for cases refractive to topical therapy may be treated with oral antifungals. *Itraconazole*, *fluconazole*, and *ketoconazole* show high efficacy in the literature; however, it is now recommended by the U.S. Food and Drug Administration (FDA) and Health Canada that oral ketoconazole not be used for superficial fungal infections when less hepatotoxic alternatives are available.^{1,2} In contrast to topical terbinafine, oral terbinafine is not effective; nor is griseofulvin.

Treatment does not vary with hyperpigmented versus hypopigmented disease. Although fungal organisms may be eradicated after 2 to 4 weeks of therapy, it may take significantly longer before the skin's normal pigmentation is restored, particularly

with hypopigmented lesions.

Relapse of PV is common due to endogenous host factors: recurrence rates have been reported as high as 60% to 90% 2 years after treatment. Both ketoconazole (a single 400-mg dose or 200 mg daily for 3 days once monthly) and itraconazole (a single 400-mg dose once monthly for 6 months) have been used in prophylactic regimens for PV, though ketoconazole is not recommended because of its potential for hepatotoxicity.

Specific Investigations

- Direct microscopy on KOH specimens
- Wood light

Malassezia organisms should be identified by skin scrapings for definitive diagnosis and are easily identified, where microscopic examination of skin scrapings reveals fungal hyphae in a typical “spaghetti and meatball” pattern. PV lesions fluoresce yellow/green or gold under Wood light; however, the examination is positive in only one third of all PV cases, most likely when the causative organism is *M. furfur*.

First-Line Therapies

Topical antifungal agents

• Ketoconazole	A
• Bifonazole	A
• Terbinafine	A
• Clotrimazole	A
• Econazole	A
• Oxiconazole	A
• Butenafine	A
• Ciclopirox	A
• Fluconazole shampoo	A
• Selenium sulfide 2.5%	B
• Tioconazole	B
• Zinc pyrithione shampoo	B

Pityriasis versicolor: a review of pharmacological treatment options

Gupta AK, Kogan N, Batra R. Exp Opin Pharmacother 2005; 6: 165–78.

This is a thorough summary of peer-reviewed studies of topical and oral therapies in the treatment of tinea versicolor until 2005. Azole topical agents have shown good mycologic cure, clinical cure, and

complete cure in many double-blind, randomized clinical trials, as have the nonspecific topical agents (zinc pyrithione shampoo, selenium sulfide, etc.) and terbinafine.

Terbinafine 1% cream and ketoconazole 2% cream in the treatment of pityriasis versicolor: a randomized comparative clinical trial

Rad F, Nik-Khoo B, Yaghmaee R, Gharibi F. Pak J Med Sci 2014; 30: 1273–6.

A randomized, single-blind trial with terbinafine 1% cream or ketoconazole 2% cream applied twice daily for 2 weeks. Cure rates (negative KOH microscopy with clinical cure) at 2 weeks (terbinafine: 72.1%; ketoconazole: 64.3%) and 8 weeks (terbinafine: 70.8%; ketoconazole: 61.9%) were not significantly different between treatments.

Can pityriasis versicolor be treated with 2% ketoconazole foam?

Cantrell WC, Elewski BE. J Drugs Dermatol 2014; 13: 855–9.

Eleven patients in this pilot study applied ketoconazole 2% foam twice daily for 2 weeks. Clinical improvement was observed over 4 weeks, and seven patients showed negative KOH microscopy.

A randomized controlled trial of combination treatment with ketoconazole 2% cream and adapalene 0.1% gel in pityriasis versicolor

Shi T-W, Zhang J-A, Tang Y-B, Yu H-X, Li Z-G, Yu J-B. J Dermatol Treat 2015; 26: 143–6.

A double-blind trial comparing combination once-daily ketoconazole cream and adapalene gel with twice-daily ketoconazole cream for 2 weeks. Total improvement rate (clinical improvement with negative microscopy) at 4 weeks was 92% in the combination group and 72% in the ketoconazole group ($p = 0.009$).

Second-Line Therapies

Oral antifungal agents

• Itraconazole	A
• Fluconazole	A

Oral prophylaxis

• Itraconazole	A
----------------	---

Systematic review of systemic treatments for tinea versicolor and evidence-based dosing regimen recommendations

Gupta AK, Lane D, Paquet M. J Cutan Med Surg 2014; 18: 79–90.

This is an extensive evidence-based review of clinical trials published up to mid-2013 that reported mycologic cure for PV. The literature supports regimens for itraconazole (200 mg/day for 5 or 7 days) and fluconazole (150 or 300 mg weekly for 2 or 4 weeks).

Efficacy of itraconazole in the prophylactic treatment of pityriasis (tinea) versicolor

Faergemann J, Gupta AK, Al Mofadi A, Abanami A, Shareaah AA, Marynissen G. Arch Dermatol 2002; 138: 69–73.

Patients achieving mycologic cure after open treatment with itraconazole 200 mg once daily for 7 days entered a double-blind, placebo-controlled trial of itraconazole prophylaxis (itraconazole or placebo: 200 mg twice daily 1 day per month for 6 consecutive months). At the end of prophylaxis, 88% of itraconazole patients remained mycologically negative, compared with only 57% of placebo-treated patients ($p < 0.001$).

Single-dose oral fluconazole versus topical clotrimazole in patients with pityriasis versicolor: a double-blind randomized

controlled trial

Dehghan M, Akbari N, Alborzi N, Sadani S, Keshtkar AA. J Dermatol 2010; 37: 699–702.

Patients were randomized to receive a single 400-mg dose of oral fluconazole with placebo cream or a placebo capsule with 1% clotrimazole cream, each applied twice daily for 2 weeks. At 12 weeks, 92% of the fluconazole group achieved complete cure, whereas 81.8% of the clotrimazole group achieved complete cure ($p=0.77$).

Third-Line Therapies

• Pramiconazole (oral triazole)	A
• Adapalene	A
• Naftifine (topical allylamine)	B
• Dapaconazole tosylate (topical imidazole)	B
• <i>Cymbopogon citratus</i> (DC) <i>Stapf</i> essential oil	B
• Isotretinoin	E

A double-blind, randomized, placebo-controlled, dose-finding study of oral pramiconazole in the treatment of pityriasis versicolor

Faergemann J, Todd G, Pather S, Vawda ZFA, Gillies JD, Walford T, et al. J Am Acad Dermatol 2009; 61: 971–6.

Participants were randomized into six pramiconazole treatment groups: (1) 100 mg taken once; (2) 200 mg taken once; (3) 200 mg taken once daily for 2 days; (4) 200 mg taken once daily for 3 days; (5) 400 mg taken once; (6) placebo taken once daily for 3 days. The primary efficacy outcome was effective treatment (negative KOH microscopy and resolution or minimal residual of clinical signs for participants with severe baseline scores). At day 28, the highest proportion of participants with an effective cure received 200 mg daily for 2 days, 84.0% (95% confidence interval [CI], 69.6–98.4) and 200 mg daily for 3 days, 84.6% (95% CI, 70.7–98.5).

Pramiconazole is not currently approved or marketed. As more data accumulate, the level of evidence may alter.

Role of adapalene in the treatment of pityriasis versicolor

Shi T, Ren X, Yu H, Tang Y. *Dermatol* 2012; 224: 184–8.

A prospective, randomized, double-blind clinical trial compared adapalene cream and 2% ketoconazole cream applied to the torso twice daily for 2 weeks. No significant difference between treatments was found at 4 weeks. Participants experienced 75% and 70% mycologic cure in the adapalene and ketoconazole groups, respectively.

Adapalene is not an antifungal drug; results are based on alterations in the skin's properties.

An open-label study of naftifine hydrochloride 1% gel in the treatment of tinea versicolor

Gold MH, Bridges T, Avakian E, Plaum S, Pappert EJ, Fleischer AB, et al. *Skinmed* 2011; 9: 283–6.

Participants received 1% naftifine gel twice daily for 2 weeks. At 6 weeks posttreatment, 50% of the participants had achieved a mycologic cure.

A randomized double-blind, non-inferiority phase II trial, comparing dapaconazole tosylate 2% cream with ketoconazole 2% cream in the treatment of pityriasis versicolor

Gobbato AA, Babadopoulos T, Gobbato CA, Ilha Jde O, Gagliano-Juca T, De Nucci G. *Expert Opin Investig Drugs* 2015; 24: 1399–407.

Treatment once daily for 28 days with dapaconazole tosylate 2% cream was noninferior to ketoconazole 2% cream for clinical and mycologic cure.

Treatment of pityriasis versicolor with topical application of essential oil of *Cymbopogon citratus* (DC) Stapf—therapeutic pilot study

Carmo ES, de Oliveira Pereira F, Cavalcante NM, Gayoso CW, de Oliveira Lima E. *An Bras Dermatol* 2013; 88: 381–5.

A phase I and phase II study of essential oil formulations compared with ketoconazole cream. Improvement was seen in both groups, with significantly more patients achieving mycologic cure in the ketoconazole cream group ($p < 0.05$).

Tinea versicolor clearance with oral isotretinoin therapy

Bartell H, Ransdell BL, Ali A. J Drugs Dermatol 2006; 5: 74–5.

This is a single case report of a 14-year-old boy presenting with acne vulgaris recalcitrant to oral antibiotic therapy, who also presented with PV infection on the upper back and shoulders. One month after starting oral isotretinoin 40 mg twice daily, the PV lesions had completely resolved. Resolution was attributed to the sebum-altering properties of isotretinoin.

The use of isotretinoin cannot be advocated because of the potential for serious side effects, particularly in females. In cases of concomitant PV and acne, no additional medication may be required for the PV infection.

Toxic epidermal necrolysis and Stevens–Johnson syndrome

Nicholas M. Craven, and Daniel Creamer

Toxic epidermal necrolysis (TEN) and Stevens–Johnson syndrome (SJS) form a spectrum of rare, potentially life-threatening conditions manifesting widespread erythematous macules or atypical target lesions and severe erosions of mucous membranes. The epithelial changes are caused by extensive apoptosis, a process initiated by drug-induced cytotoxic T lymphocytes. A number of proapoptotic molecules, including $\text{TNF-}\alpha$ and $\text{IFN-}\gamma$, link drug-induced immune responses to keratinocyte damage. Ultimately, keratinocyte death is caused by directly acting apoptosis mediators, with the major trigger being granulysin. Confluence of cutaneous lesions leads to epidermal loss, which by definition involves less than 10% of total body surface area in SJS, 10% to 30% in overlap cases, and more than 30% in TEN. Complications develop similarly to those seen after burns. In the majority of cases, SJS and TEN (SJS/TEN) can be attributed to a drug reaction.

Management Strategy

The causative drug should be identified and discontinued. In general, drugs introduced in the 4 weeks before the onset of symptoms are usually

responsible. The most common drugs causing SJS/TEN are allopurinol, carbamazepine, lamotrigine, nevirapine, oxycam nonsteroidal antiinflammatory drugs (NSAIDs), phenobarbital, phenytoin, sulfasalazine, sulfamethoxazole, and other sulfur antibiotics.

Extensive epidermal loss in SJS/TEN is accompanied by numerous systemic sequelae, many of which are life threatening. Therefore the patient should be managed in a specialist intensive care unit or burn unit for the delivery of critical care management and specialist nursing. Supportive therapy is directed at fluid replacement, maintaining a warm environment, nutritional support, analgesia, organ support (when necessary), surveillance for infection, and appropriate dressings. *Fluid replacement* requirements depend on the extent of involvement of the skin and may be 5 to 7 L in the first 24 hours. *The ambient temperature* should be raised to 25°C. *Nutritional support* may require nasogastric tube feeding until the oral mucosa has healed. *Analgesia* with opiates is often necessary. *Infection surveillance* includes taking skin swabs from lesional skin throughout the acute phase and sending these for bacteriology. Administration of prophylactic antibiotics is not recommended, as this increases skin colonization (particularly with *Candida albicans*) and promotes resistance. All lines should be checked daily for signs of infection, changed at least every 3 days, and the tips of all discarded lines and catheters sent for culture. If signs of sepsis develop (rising or falling temperature, rigors, hypotension, fall in urine output, or deterioration of respiratory status, diabetic control, or level of consciousness), initial antibiotic therapy can be guided by the results of swabs taken from the skin and mucous membranes. Blisters should be decompressed by piercing and expression of tissue fluid. Blister roofs and detached epidermis can be left in situ to act as a biologic dressing. Folded, necrosed epidermis should be removed gently.

Ophthalmologic review should be obtained as soon as possible after diagnosis to minimize the risk of conjunctival scarring and blindness. Regular instillation of an ocular lubricant, topical antibiotic, and corticosteroid drops is recommended. Separation of conjunctival adhesions must be carried out by an ophthalmologist or ophthalmically trained nurse. Oral and nasal debris should be removed regularly. Antiinflammatory and antiseptic mouthwashes must be used frequently. Tracheal and bronchial involvement is an underappreciated manifestation of SJS/TEN and may be a marker of

disease severity and mortality. Respiratory failure can occur, requiring ventilation.

The use of *systemic corticosteroids* in the management of TEN and SJS remains controversial (see later). Several reports suggest that the use of corticosteroids increases morbidity and mortality, usually by increasing the risk of sepsis. Conversely, a number of case reports and short studies advocate the use of high-dose corticosteroids in the early stages of the evolution of these conditions. It is therefore possible that high-dose corticosteroids may prove beneficial in aborting further epithelial loss in patients with evolving SJS/TEN, but this has not yet been tested in a randomized controlled trial. Nevertheless, it is generally accepted that continuing administration of corticosteroids is counterproductive once extensive skin loss has occurred.

Several other potential disease-modifying treatments (*intravenous immunoglobulin [IVIG], cyclosporin, pentoxifylline, plasmapheresis, anti-TNF agents*) have been reported in small numbers of patients, but there is currently no strong evidence base for recommending any specific intervention other than supportive care.

Survivors of SJS/TEN should avoid exposure to the culprit drug and related compounds.

Specific Investigations

- Histology of a skin biopsy
- Hematologic and biochemical monitoring, including glucose and bicarbonate
- Chest x-ray

Established TEN can usually be diagnosed clinically. Biopsy and immunofluorescence of an affected area of skin can exclude conditions such as staphylococcal scalded skin syndrome and paraneoplastic pemphigus.

Stevens–Johnson syndrome and toxic epidermal necrolysis: assessment of medication risks with emphasis on recently marketed drugs. The EuroSCAR study

Mockenhaupt M, Viboud C, Dunant A, Naldi L, Halevy S, Bouwes Bavinck JN, et al. *J Invest Dermatol* 2008; 128: 35–44.

The results of a multinational case-control study of risk for developing SJS and TEN from various drugs, showing a strong

association for nevirapine and lamotrigine; a weaker association for sertraline, pantoprazole, and tramadol; and confirming a strong association for previously recognized culprit drugs: sulfonamide antibiotics, allopurinol, carbamazepine, phenobarbital, phenytoin, and oxycam NSAIDs.

SCORTEN: a severity-of-illness score for toxic epidermal necrolysis

Bastuji-Garin S, Fouchard N, Bertocchi M, Roujeau JC, Revuz J, Wolkenstein P. J Invest Dermatol 2000; 115: 149–53.

Assessment of seven clinical parameters within the first 24 hours of admission (age over 40 years; history of malignancy; tachycardia >120 bpm; skin loss >10%; urea >10 mmol/L; glucose >14 mmol/L; bicarbonate <20 mmol/L) can be used to predict risk of mortality (score 0 or 1: 3% risk of death; 2: 12%; 3: 35%; 4: 58%; 5+: 90%).

Comprehensive survival analysis of a cohort of patients with Stevens-Johnson syndrome and toxic epidermal necrolysis

Sekula P, Dunant A, Mockenhaupt M, Naldi L, Bouwes Bavinck JN, Halevy S, et al. for the RegiSCAR study group. J Invest Dermatol 2013; 133: 1197–204.

All-cause mortality rates at 6 weeks in this cohort of 460 patients (recruited between 2003 and 2007) were 12%, 29%, and 46% for SJS, SJS/TEN overlap, and TEN, respectively.

First-Line Therapies

• Supportive measures	E
• Withdrawal of culprit drug	E
• Transfer to a specialist unit	E

UK guidelines for the management of Stevens-Johnson syndrome/toxic epidermal necrolysis in adults 2016

Creamer D, Walsh SA, Dziewulski P, Exton LS, Lee HY, Dart JK, et al. Br J Dermatol 2016; 174: 1194–227.

This guideline is a review of all aspects of SJS/TEN management in adults, concentrating on the details of supportive care. Recommendations for practical use are highlighted.

Toxic epidermal necrolysis and Stevens–Johnson syndrome: does early withdrawal of causative drugs decrease the risk of death?

Garcia-Doval I, LeCleach L, Bocquet H, Otero XL, Roujeau JC. Arch Dermatol 2000; 136: 323–7.

Early discontinuation of the causative drug improved prognosis in this study of 113 patients.

ALDEN, an algorithm for assessment of drug causality in Stevens–Johnson syndrome and toxic epidermal necrolysis: comparison with case-control analysis

Sassolas B, Haddad C, Mockenhaupt M, Dunant A, Liss Y, Bork K, et al. Clin Pharmacol Ther 2010; 88: 60–8.

Seventy percent to 80% of cases of SJS, TEN, and SJS/TEN overlap are attributable to drugs. This paper describes a validated algorithm for assessing the likelihood of causality of drugs in such cases.

A multicenter review of toxic epidermal necrolysis treated in U.S. burn centers at the end of the twentieth century

Palmieri TL, Greenhalgh DG, Saffle JR, Spence RJ, Peck MD, Jeng JC, et al. J Burn Care Rehab 2002; 23: 87–96.

A retrospective multicenter study of 199 patients admitted with TEN to 15 burn centers from 1995 to 2000. Overall mortality was 32%, increasing to 51% for patients transferred to a burn center more than 1 week after the onset of TEN.

There are several studies (but no controlled trials) showing benefit from early transfer of TEN patients to specialist units.

Second-Line Therapies

• Ciclosporin	B
• Systemic corticosteroids	B
• Intravenous immunoglobulin	B

Open trial of cyclosporin treatment for Stevens–Johnson syndrome and toxic epidermal necrolysis

Valeyrie-Allanore L, Wolkenstein P, Brochard L, Ortonne N, Maître B, Revuz J, et al. *Br J Dermatol* 2010; 163: 847–53.

Twenty-nine patients with SJS ($n=10$), SJS/TEN overlap ($n=12$), and TEN ($n=7$) were treated with cyclosporin via a nasogastric catheter at a dose of 3 mg/kg for 10 days, then 2 mg/kg for 10 days, and finally 1 mg/kg for 10 days. Treatment was tolerated well in most patients, and although the prognostic score predicted 2.75 deaths, none occurred. In addition, the progression of detachment of epidermis seemed lower than expected.

Retrospective review of Stevens-Johnson syndrome/toxic epidermal necrolysis treatment comparing intravenous immunoglobulin with cyclosporine

Kirchhof MG, Miliszewski MA, Sikora S, Papp A, Dutz JP. *J Am Acad Dermatol* 2014; 71: 941–7.

Single-center retrospective study of 64 patients with SJS/TEN. Predicted mortality based on SCORTEN was compared with actual mortality for patients treated with either cyclosporin (3–5 mg/kg/day for up to 7 days) or IVIG (2–5 g/kg total dose). The results showed an apparently improved mortality with ciclosporin over that predicted by SCORTEN (standardized mortality ratio [SMR] 0.43) compared with an apparently increased mortality with IVIG (SMR 1.43). Although aware of the limitations of the study, the authors concluded that the results suggested a possible benefit from using ciclosporin in the treatment of TEN and SJS.

Treatment of toxic epidermal necrolysis with cyclosporin A

Arévalo JM, Lorente JA, González-Herrada C, Jiménez-Reyes J. *J*

Trauma 2000; 48: 473–8.

An improved outcome was reported in 11 consecutive patients with TEN treated with cyclosporin 3 mg/kg daily, compared with six historical controls treated with cyclophosphamide and corticosteroids. Both groups were of comparable age, with similar extent of skin loss and delay between onset of TEN and admission. Patients treated with cyclosporin had more rapid reepithelialization, were less likely to suffer multiorgan failure, and had a lower mortality (0 of 11 vs. 3 of 6).

There are now several reports of the successful use of cyclosporin in SJS/TEN. Because most of the hazards of this drug are associated with long-term use, it seems logical to use this drug in SJS/TEN, as treatment will only be needed for a few days.

Effects of treatments on the mortality of Stevens–Johnson syndrome and toxic epidermal necrolysis: a retrospective study on patients included in the prospective EuroSCAR study

Schneck J, Fagot JP, Sekula P, Sassolas B, Roujeau JC, Mockenhaupt M. J Am Acad Dermatol 2008; 58: 33–40.

A large, multicenter, retrospective study of treatment of 281 patients with TEN enrolled in EuroSCAR (a case-control study of risk factors for severe cutaneous adverse reactions) showed no significant effect on mortality with the administration of IVIG, but a trend for beneficial effect of corticosteroids was considered worthy of further exploration.

Corticosteroids in Stevens-Johnson Syndrome/toxic epidermal necrolysis: current evidence and implications for future research

Law EH, Leung M. Ann Pharmacother 2015; 49: 335–42.

Six studies that used steroids for SJS, TEN, and/or overlap were included in this review. All were retrospective cohort studies with no case-control or cross-sectional studies. Only one reported a statistically significant mortality benefit with steroid use (odds ratio = 0.4; 95% confidence interval [CI] = 0.2–0.9). None of the studies reported adverse event rates. The authors concluded that there is a need for prospective, randomized controlled trials to provide more definitive evidence supporting steroid use in patients with SJS, TEN, and/or overlap.

Systematic review of treatments for Stevens-Johnson syndrome

and toxic epidermal necrolysis using the SCORTEN score as a tool for evaluating mortality

Roujeau JC, Bastuji-Garin S. *Ther Adv Drug Saf* 2011; 2: 87–94.

A pooled analysis of published series addressing treatment efficacy by comparing the mortality observed to the mortality predicted by the SCORTEN score. The analyzed series comprised a total of 439 patients. Supportive care was used only in 199 patients with a pooled mortality ratio (MR) of 0.89 (CI, 0.67–1.16; $p=0.43$), corticosteroids were administered to 78 patients with a pooled MR of 0.92 (CI, 0.53–1.48; $p=0.84$), and IVIG in 162 with a pooled MR of 0.82 (CI 0.58–1.12, $p=0.23$). In conclusion, even though this analysis had some limitations, it strongly suggested that neither corticosteroids nor IVIG provide any important improvement in mortality over that predicted by SCORTEN in SJS and TEN.

The efficacy of intravenous immunoglobulin for the treatment of toxic epidermal necrolysis: a systematic review and meta-analysis

Huang YC, Li YC, Chen TJ BJ. *Dermatol* 2012; 167: 424–32.

A meta-analysis evidence-based examination of IVIG efficacy in TEN compared the clinical differences between (1) high-dose ($\geq 2\text{g/kg}$) and low-dose ($< 2\text{g/kg}$) IVIG treatment in adult patients and (2) pediatric and adult patients treated with IVIG.

Although high-dose IVIG exhibited a trend toward improved mortality and children treated with IVIG had a good prognosis, the authors concluded that the evidence overall did not support a clinical benefit of IVIG and stated that randomized controlled trials are necessary.

The role of intravenous immunoglobulin in toxic epidermal necrolysis: a retrospective analysis of 64 patients managed in a specialized center

Lee HY, Lim YL, Thirumoorthy T, Pang SM. *Br J Dermatol* 2013; 169: 1304–9.

This single-center study of use of IVIG in the management of 64 patients with SJS/TEN overlap and TEN demonstrated no survival benefit even when corrected for IVIG dosages.

Intravenous immunoglobulin in the treatment of Stevens-Johnson syndrome and toxic epidermal necrolysis: a meta-

analysis with metaregression of observational studies

Barron SJ, Del Vecchio MT, Aronoff SC. *Int J Dermatol* 2015; 54: 108–15.

Thirteen studies met the inclusion criteria for this meta-analysis, eight of which included a control group. Although there was no significant overall benefit of using IVIG in SJS or TEN (overall standardized MR 0.814, 95% CI 0.617–1.076), the metaregression found a strong inverse correlation between IVIG dosage and mortality, and the authors concluded that IVIG at dosages of ≥ 2 g/kg appears to significantly decrease mortality in patients with SJS or TEN.

A systematic review of treatment of drug-induced Stevens-Johnson syndrome and toxic epidermal necrolysis in children

Del Pozzo-Magana BR, Lazo-Langner A, Carleton B, Castro-Pastrana LI, Rieder MJ. *J Popul Ther Clin Pharmacol* 2011; 18: e121–33.

The four main treatment modalities in the included studies were IVIG, steroids (prednisolone, methylprednisolone, dexamethasone), dressings with or without surgical debridement, and supportive treatment alone. A number of miscellaneous treatments were reported: of 12 patients, 3 received ulinastatin, 4 received plasmapheresis, 2 received IV pentoxifylline, and the last 3 patients received a different treatment each (cyclosporine, methylprednisone/G-CSF, and methylprednisolone/IVIG). Steroids and IVIG seem to improve the outcome of SJS and TEN in pediatric patients, but results from different reports are variable. Patients treated only with care support seem to have higher morbidity and mortality. The authors conclude that further studies are necessary to define optimal management of TEN and SJS in children.

As with all data on treatment of SJS/TEN, interpretation of the available literature is limited by lack of uniformity in the treatment regimens used, by the lack of adequate control data, and/or by the relatively small size of the studies. Systematic reviews and meta-analyses are helpful in this respect, but mainly serve to confirm the lack of strong evidence of benefit for any intervention other than best supportive care delivered in a suitable setting.

Third-Line Therapies

• Plasmapheresis	C
• Pentoxifylline	E
• Anti-TNF therapy	E

Plasmapheresis as an adjunct treatment in toxic epidermal necrolysis

Egan CA, Grant WJ, Morris SE, Saffle JR, Zone JJ. J Am Acad Dermatol 1999; 40: 458–61.

A retrospective study of 16 patients, 6 of whom were selected for plasmapheresis (one to four treatments) based on rapid progression of disease in the 24 hours after admission. None of the patients treated with plasmapheresis died, whereas 4 of the other 10 patients did die.

Lack of significant treatment effect of plasma exchange in the treatment of drug-induced toxic epidermal necrolysis?

Furubacke A, Berlin G, Anderson C, Sjoberg F. Intens Care Med 1999; 25: 1307–10.

The outcomes in eight patients with SJS/TEN who received one to eight plasma exchange treatments was compared with outcomes in patients from two other centers that used almost identical treatment protocols but without plasma exchange. The results showed no benefit in terms of mortality (12.5%), time to reepithelialization, or duration of stay in the burn intensive care unit. The authors concluded that the results did not support the use of plasma exchange in the treatment of SJS/TEN.

Pentoxifylline in toxic epidermal necrolysis and Stevens–Johnson syndrome

Sanclemente G, De La Roche CA, Escobar CE, Falabella R. Int J Dermatol 1999; 38: 878–9.

Two children with SJS and SJS/TEN overlap were treated with

intravenous pentoxifylline 12 mg/kg daily. In both cases skin loss stopped on commencement of treatment; in one child the skin deteriorated when pentoxifylline was temporarily discontinued.

Toxic epidermal necrolysis successfully treated with infliximab

Zárate-Correa LC, Carrillo-Gómez DC, Ramírez-Escobar AF, Serrano-Reyes C. *J Investig Allergol Clin Immunol* 2013; 23: 61–3.

This report describes the use of infliximab (single infusion of 300 mg) in four patients with TEN. The infusions were given between 2 and 8 days after onset of symptoms due to progression of skin loss. All four patients recovered, although three developed bacteremia, which responded to antibiotic therapy.

Etanercept therapy for toxic epidermal necrolysis

Paradisi A, Abeni D, Bergamo F, Ricci F, Didona D, Didona B. *J Am Acad Dermatol* 2014; 71: 278–83.

Ten patients with SJS/TEN were treated with a single dose of etanercept. There was no control group. None of the patients died, despite a mean predicted mortality rate of 50%.

Randomised comparison of thalidomide versus placebo in toxic epidermal necrolysis

Wolkenstein P, Latarjet J, Roujeau J-C, Duguet C, Boudeau S, Vaillant L, et al. *Lancet* 1998; 352: 1586–9.

Patients with TEN were randomized to either a 5-day course of thalidomide 400 mg daily (12 patients) or placebo (10 patients). The study was stopped early because of excess mortality in the treatment arm.

Transient acantholytic dermatosis (Grover disease)

Murtaza Khan, and John Berth-Jones

Grover disease is an uncommon disorder characterized clinically by discrete erythematous, edematous papulovesicles or keratotic papules, which are usually pruritic, and histologically focal acantholytic dyskeratosis. It can be self-limiting or chronic. It is more common in middle-aged and elderly people, especially men, and involves mainly the trunk. The evolution is acute or chronic, lasting weeks to months, and it may be persistent or recurrent. The etiology is unknown, but excessive UV exposure, heat, sweating, and ionizing radiation are linked to the disease. Drugs, chemotherapeutic agents, dialysis, and cancers are also reported triggers. Other skin disorders such as psoriasis or eczema of various types may coexist.

Management Strategy

Histology is helpful, but immunofluorescence does not aid in diagnosis.

Treatment is difficult, and the evidence base is anecdotal. Patients should be advised to avoid excessive sun exposure, strenuous exercise, heat, and occlusive fabrics. In mild cases, simple antipruritic measures such as avoidance of soap, simple emollients, and soothing baths with bath oils or colloidal oatmeal may be of benefit. Wet compresses with zinc oxide, calamine, or topical corticosteroids may help relieve the itching.

Topical calcipotriol (ointment) twice daily 50 µg/g may be helpful after 3 to 4 weeks of treatment.

Systemic therapy may be indicated in more extensive and persistent disease. *Oral vitamin A* has been recommended in the past. The aromatic retinoid *acitretin* has been used successfully in doses of 0.5 mg/kg daily. *Isotretinoin* 40 mg daily has been used for periods ranging from 2 to 12 weeks. It may be administered on a reducing regimen if the initial response is rapid, with a maintenance dose of 10 mg daily.

Systemic corticosteroids have been used to suppress inflammation and pruritus, but relapses frequently occur on drug withdrawal.

Psoralen with UVA (PUVA) may be useful, but an initial exacerbation may occur. There are reports of the success of narrowband UVB and of medium-dose UVA1 phototherapy.

Topical 5-fluorouracil, dapsone, antibiotics, and cryotherapy are ineffective. Recently rituximab and etanercept have been reported to be useful.

Specific Investigation

- Skin biopsy

First-Line Therapies

• Emollients	D
• Avoid heat/sweating	D
• Topical corticosteroids	D

Transient acantholytic dermatosis

Heenan PJ, Quirk CJ. Br J Dermatol 1980; 102: 515–20.

This study looked at a series of 24 cases of transient acantholytic dermatosis. Most of them required topical fluorinated corticosteroids to control the pruritus, and two required intermittent courses of oral corticosteroids.

Incidence of transient acantholytic dermatosis (Grover's disease) in a hospital setting

French LE, Piletta PA, Etienne A, Salomon D, Saurat JH. Dermatology 1999; 198: 410–1.

A prospective study of 28 hospital inpatients diagnosed with Grover disease. In over 80% of cases the duration of hospitalization exceeded 2 weeks and was associated with strict bed rest. The authors suggested a sweat-related pathogenesis.

Second-Line Therapies

• Calcipotriol	E
• Tacalcitol	E
• Systemic corticosteroids	D
• Vitamin A	D

Treatment of Grover's disease with calcipotriol (Dovonex)

Keohane SG, Cork MJ. Br J Dermatol 1995; 132: 832–3.

A 50-year-old man had a 13-month history of Grover disease that responded poorly to oxytetracycline, topical corticosteroids, dapsone, and etretinate. Lesions cleared after hospitalization and prednisone 100 mg daily, but he relapsed with any reduction in dose. Oral corticosteroids were stopped, and he was commenced on an alternating regimen of calcipotriol ointment at night and 0.025% betamethasone valerate ointment (we presume in the morning). There was complete clearance of lesions after 1 month of treatment, but the disease relapsed when treatment was stopped.

Successful treatment of Grover's disease with calcipotriol

Mota AV, Correia TM, Lopes JM, Guimaraes JM. Eur J Dermatol 1998; 8: 33–5.

An 84-year-old man with a 2-year history of Grover disease improved significantly, despite initial moderate irritation, after a 3-week course of calcipotriol 50 µg/g twice daily. Lesions did not recur during a 6-month follow-up.

Treatment of Grover's disease with tacalcitol

Hayashi H. Clin Exp Dermatol 2002; 27: 160–1.

A 31-year-old man with a 2-month history of Grover disease who failed to respond to topical corticosteroid was commenced on tacalcitol ointment twice daily. He improved dramatically within 1 week and was in remission after 1 month.

Treatment of transient acantholytic dermatosis

Rohr JR, Quirk CJ. Arch Dermatol 1979; 115: 1033–4.

Eight patients were treated with vitamin A 50,000 units three times a day for up to 2 weeks; all patients responded. Once initial improvement was noted the dose was reduced to 50,000 units daily as maintenance or for several weeks. No signs of toxicity were noted. One patient required reinstitution of the drug due to recurrence on cessation of treatment.

Third-Line Therapies

• Systemic retinoids (acitretin/etretinate/isotretinoin)	E
• PUVA	E
• UVA1	E
• Photodynamic therapy	E
• Trichloroacetic acid	E
• Etanercept	E
• Rituximab	E

Persistent acantholytic dermatosis

Dodd HJ, Sarkany I. Clin Exp Dermatol 1984; 9: 431–4.

A case report of a 41-year-old man with a 5-year history of an itchy truncal and lower limb rash consistent with persistent acantholytic dermatosis. Bath emollients and aqueous cream British pharmacopoeia afforded minor relief. Etretinate (50 mg daily) cleared the skin lesions and reduced the itching.

Etretinate has been replaced by its active metabolite acitretin. Lower doses

of the latter may be effective.

Grover's disease treated with isotretinoin

Helfman RJ, Gables C. J Am Acad Dermatol 1985; 12: 981–4.

Four patients with biopsy-proven Grover disease responded to 40 mg daily of isotretinoin for 2 to 4 months. In two patients most lesions had cleared after 3 to 4 weeks of treatment. Their dose was reduced by 10 mg daily for a further 8 weeks. One patient required 40 mg daily for 8 weeks. These patients remained in remission for up to 10 months after treatment. The final patient obtained partial relief and then discontinued treatment because of elevated triglycerides.

Response of transient acantholytic dermatosis to photochemotherapy

Paul BS, Arndt KA. Arch Dermatol 1984; 120: 121–2.

A 59-year-old man with persistent Grover disease was unresponsive to oral prednisone and vitamin A (300,000 units daily). PUVA was initiated with 50 mg (0.6 mg/kg) methoxsalen and 2 J/cm² of UVA. Treatment was twice weekly, and the UVA dosage was increased by 0.5 J/cm² with each treatment. The patient experienced a flare after four treatments, but improved by week 6, with maximal improvement by week 8. Therapy was then tapered off over the next 4 weeks, with complete clearing. No recurrence had occurred 25 months after therapy.

Reports show that approximately 10 treatments are required for resolution of pruritus, and 20 to 30 treatments may be needed to clear the eruption.

Medium-dose ultraviolet A1 phototherapy in transient acantholytic dermatosis (Grover's disease)

Breuckmann F, Appelhans C, Altmeyer P, Kreuter A. J Am Acad Dermatol 2005; 52: 169–70.

A 78-year-old man with persistent Grover disease had failed to respond to topical and oral corticosteroids. He was treated with a medium-dose UVA1 cold light monophototherapy containing a special filtering and cooling system (21°C). Irradiation (50 J/cm², 1.9 J/cm²/minute; 26 minutes), six times weekly for 3 weeks, then three times weekly for 3 weeks. A total of 24 treatments was given with a cumulative dose of 1200 J/cm². Complete remission was achieved after 4 weeks, with no subsequent relapse.

Successful novel treatment of recalcitrant transient acantholytic dermatosis (Grover disease) using red light 5-aminolevulinic acid photodynamic therapy

Liu S, Letada PR. *Dermatol Surg* 2013; 39: 960–1.

This appeared helpful in one case.

Effective treatment of persistent Grover's disease with trichloroacetic acid peeling

Kouba DJ, Dasgeb B, Deng AC, Gaspari AA. *Dermatol Surg* 2006; 32: 1083–8.

A 46-year-old woman had a 6-month history of progressive Grover disease with intractable pruritus. She failed to respond to topical calcipotriene (Dovonex). She was treated with an even, light application of 40% (w/v) trichloroacetic acid (TCA)—single-pass strokes with TCA-dampened gauze. Individual lesions of Grover disease were identified and were re-treated with 40% TCA using a cotton-tipped applicator. Three weeks postprocedure she had reepithelialized, was disease free, and was still in remission 8 months later.

The authors stress that practitioners not accustomed to using TCA in office applications should use low-strength formulations such as 20% to 30% to avoid scarring.

Use of etanercept in treating pruritus and preventing new lesions in Grover disease

Norman R, Chau V. *J Am Acad Dermatol* 2011; 64: 796–8.

A 55-year-old man had a 2-year history of Grover disease that did not respond to topical or oral steroids and antihistamines. Isotretinoin given for 2 months resulted in improvement of his pruritus but was discontinued after he had a myocardial infarction. He was prescribed etanercept 50 mg subcutaneously twice weekly for 6 weeks, which reduced the pruritus by 98%. Over the next 4 months he had very mild symptoms and did not develop any new lesions.

Remission of transient acantholytic dermatosis after the treatment with rituximab for follicular lymphoma

Ishibashi M, Nagasaka T, Chen KR. *Clin Exp Dermatol* 2008; 33: 206–7.

An 80-year-old woman developed Grover disease simultaneously with a relapse of follicular lymphoma. Six years before this episode

her lymphoma had been treated with rituximab. She was given rituximab again, and her skin lesions cleared within a week. The lymphoma improved initially, but after nine cycles of treatment she suffered another relapse. Her skin lesions did not recur.

Trichotillomania

Mio Nakamura, and John Koo

Trichotillomania, or hair-pulling disorder, is the impulsive, repetitive action of pulling out hair, resulting in significant hair loss. Any region of the body with hair can be involved, with the eyebrows, eyelashes, and scalp comprising the most common sites. The reported prevalence of trichotillomania is approximately 0.6% in the general population. It is predominantly observed in females, with an early age of onset averaging between 11 and 13 years.

The *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (DSM-V), categorizes trichotillomania under “obsessive-compulsive disorder,” which is a change from the previous editions of DSM, which categorized trichotillomania under “impulse disorders.” Obsessive-compulsive disorders include intrusive thoughts or urges that are experienced as unwanted (obsession), often necessitating repetitive behaviors or rituals to help alleviate the otherwise intolerable anxiety (compulsion). The following are the DSM-V diagnostic criteria for trichotillomania:

- A. Recurrent pulling out of one’s hair resulting in noticeable hair loss.
- B. An increasing sense of tension immediately before pulling out the hair or when attempting to resist the behavior.
- C. Pleasure, gratification, or relief when pulling out the hair.
- D. The disturbance is not better accounted for by another mental disorder and is not due to general medical conditions.
- E. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Patients with trichotillomania often admit to hair pulling; however, some patients are unwilling or ashamed to acknowledge the self-inflicted nature of their skin findings, whereas others are not conscious of their hair pulling. Some patients practice specific rituals after hair pulling including rolling the hair between the fingers, running the hair over the lips or through the teeth, and biting the hair. In rare cases, the patient may also eat the hair root (trichorhizophagia) as a secretive activity, and in even rarer cases the whole hair is eaten (trichophagia). It is possible to develop gastrointestinal hairballs (trichobezoars), which have a high morbidity and can be fatal. Children with trichotillomania who present with episodes of obscure abdominal pain, weight loss, nausea, vomiting, anorexia, and foul breath should be investigated for gastric trichobezoars.

Many patients with trichotillomania have underlying psychiatric disease. It is estimated that up to 80% of patients with trichotillomania have comorbid psychiatric disease, most commonly anxiety and depression. Patients with trichotillomania may have other types of obsessive-compulsive disorders, specifically body-focused repetitive behavioral disorders (BFRBD), such as skin picking and nail biting. The patient may be delusional in cases such as trichophobia, in which an individual has an irrational fear of hair.

Diagnosis

Patients with trichotillomania present with alopecia that is generally irregular and nonscarring. Broken, sparse hair on a background of excoriations is often observed. Hairs are broken at different lengths on the scalp. The diagnosis of trichotillomania can be made on a clinical basis with careful examination of the scalp. Dermatologic differential diagnoses that should be ruled out include alopecia areata, androgenic alopecia, alopecia mucinosa, tinea capitis, lichen planopilaris, folliculitis decalvans, and discoid lupus erythematosus. Tinea capitis may be ruled out by the absence of scaling and negative fungal culture. Laboratory investigations such as complete blood count, thyroid function tests, and iron levels may also be indicated. Dermoscopy can be useful to detect black dots (exclamation points) or broken hairs, as well as curled hairs, suggestive of trichotillomania. However, because the dermoscopy findings of trichotillomania can overlap with other causes of hair loss such as alopecia areata, a skin biopsy may be indicated in some cases. Trichotillomania presents histologically as an increased number of catagen hairs, traumatized hair bulbs in the absence of perifollicular inflammation (trichomalacia), empty follicles, follicular keratin debris, and melanin pigment casts.

Management Strategy

Trichotillomania can cause significant social isolation and psychological disability; therefore treatment of this disorder is important to restore the patient's quality of life. Treatments that have been shown to be effective for trichotillomania are largely psychological in nature and include behavioral therapy, including habit-reversal therapy, in both pediatric and adult populations. Habit-reversal training is a form of behavioral therapy that focuses on four key aspects: awareness (increase awareness of hair-pulling behavior), competing response training (perform a specific action when there is an urge to pull hair), social support or contingency management (a person who reinforces the former), and stimulus control (minimize the influence of environmental factors on pulling behavior). Habit-reversal training has been shown to decrease repetitive, self-inflicted behaviors. Children can benefit from behavioral therapy to prevent worsening of their disease into adulthood.

Effective pharmacologic treatments involve treating the underlying psychiatric disease. The first-line pharmaceutical approach depends on the nature of the involved underlying psychopathology; the underlying causes of trichotillomania such as anxiety, depression, substance abuse, and eating disorders should be treated accordingly.

Studies of pharmacologic therapy for the treatment of trichotillomania have been limited. The tricyclic antidepressant clomipramine (Anafranil), indicated for obsessive-compulsive disorder, is the most studied medication for trichotillomania, and it has been shown to reduce the frequency of hair-pulling urges. Clomipramine is started at a dose of 25 mg per day and is titrated up to 125 to 250 mg per day. Side effects include headache, orthostatic hypotension, anticholinergic effects, QT prolongation, and seizures.

High-dose selective-serotonin reuptake inhibitors (SSRIs), such as paroxetine (Paxil), fluoxetine (Prozac), or sertraline (Zoloft), can also be used to treat trichotillomania. Paxil is typically started at 20 mg daily initially and then increased by 10 mg weekly to up to 50 to 60 mg per day. Fluoxetine is started at a dose of 10 mg per day and titrated up to an effective dose, which usually ranges from 20 to 80 mg per day. The usual starting dose of sertraline is 50 mg per day, with an effective dose ranging typically from 50 to 200 mg per day. Side effects of SSRIs include gastrointestinal upset, headache, sexual dysfunction, and suicidality. Although SSRIs alone have not shown significant evidence to effectively treat trichotillomania, the combination of pharmacotherapy and habit-reversal training has been shown to be effective in decreasing the frequency of hair pulling. Atypical antipsychotics such as olanzapine (Zyprexa) and aripiprazole (Abilify) have been reported to successfully treat trichotillomania in case reports.

Specific Investigations

- Hair microscopy
- Dermoscopy
- Scalp biopsy
- Laboratory testing (complete blood count, thyroid stimulating hormone, ferritin)

Trichotillomania. Presentation, etiology, diagnosis and therapy

Walsh KH, McDougle CJ. Am J Clin Dermatol 2001; 2: 327–33.
This is a comprehensive and detailed review of trichotillomania.

First-Line Therapies

• Behavioral therapy/habit-reversal therapy	A
---	---

Behavior therapy for pediatric trichotillomania: a randomized controlled trial

Franklin ME, Edson AL, Ledley DA, Cahill SP. J Am Acad Child Adolesc Psychiatry 2011; 50: 763–71.

Behavioral therapy produced superior outcomes compared to a control group in a randomized controlled trial of pediatric patients with trichotillomania.

Psychological treatments for trichotillomania

Rehm I, Moulding R, Nedeljkovic M. Australas Psychiatry 2015; 23: 365–8.

Advances in the understanding of the phenomenology of trichotillomania have led to the augmentation of behavioral treatments with dialectical behavior therapy and acceptance and commitment therapy. Further studies of treatment component efficacy and cognitive behavioral models are needed.

Behavioral treatment of trichotillomania: 2-year follow-up results

Keijsers GP, van Minnen A, Hoogduin CA, Klaassen BN, Hendriks MJ, Tanis-Jacobs J. Behav Res Ther 2006; 44: 359–70.

The manual-based behavioral therapy consisted of self-control procedures offered in six sessions. The area of the patch of trichotillomania was assessed and was reduced by 49% and 70% at 3 months and 2 years. Better 2-year follow-up results were associated with lower pretreatment levels of depressive symptoms and with complete abstinence from hair pulling immediately after treatment.

Second-Line Therapies

• Clomipramine	B
• SSRI	B
• Combination of habit-reversal therapy and pharmacotherapy	C

Pharmacotherapy of trichotillomania (hair pulling disorder): an updated systematic review

Rothbart R, Stein DJ. Expert Opin Pharmacother 2014; 15: 2709–19.

A systematic review of clinical trials of pharmacotherapeutic agents for the treatment of trichotillomania. Although limited, various clinical trials overall have shown modest benefit of pharmacotherapy such as clomipramine and SSRIs.

Single modality versus dual modality treatment for trichotillomania

Dougherty D. J Clin Psychiatry 2006; 67: 1086–92.

Habit reversal and SSRI drug therapy together was better than either alone.

Third-Line Therapy

• Antipsychotics	A
-------------------------	----------

Systematic review. Pharmacologic and behavioral treatment for trichotillomania

Block M, Landeros-Weisenberger A, Dombrowski P, Kelmendi B, Wegner R, Nudel J, et al. Biol Psychiatry 2007; 62: 839–46.

There are multiple case reports and case series reporting favorable responses to antipsychotics as monotherapy and augmentation agents in the literature. Controlled trials are necessary.

Tuberculosis and tuberculids

Yasaman Mansouri, and John Berth-Jones

Cutaneous tuberculosis (TB) is an infection caused by *Mycobacterium tuberculosis*, and occasionally by *M. bovis* and bacillus Calmette-Guérin (BCG), an attenuated strain of *M. bovis*. The spectrum of clinical manifestations varies depending on the host's

immunity, the route of infection, the infectious load, and virulence factors. Cutaneous disease can occur by direct inoculation from an exogenous source (tuberculous chancre and tuberculosis verrucosa cutis/warty TB; rarely lupus vulgaris) or from an endogenous source, via lymphatic, hematogenous, or contiguous spread and causes periorificial TB, lupus vulgaris (LV), scrofuloderma, acute miliary TB, and tuberculous gumma. Scrofuloderma is the most common variant worldwide. The tuberculids are a group of “hypersensitivity” reactions to extracutaneous sources of *M. tuberculosis* (tuberculous antigen) in individuals with high immunity. These include erythema induratum of Bazin, erythema nodosum, lichen scrofulosorum, papulonecrotic tuberculid, and nodular tuberculid.

Management Strategy

The diversity of clinical findings, the relatively rare occurrence of cutaneous disease, and the difficulty in demonstrating acid-fast bacilli (AFB) on histology specimens often lead to misdiagnosis or significant delays in correctly identifying cutaneous TB, so a high index of suspicion is required for prompt diagnosis. Initially this is based on the correlation of clinical findings with histopathologic identification of granulomatous inflammation with or without caseous necrosis on tissue samples. The gold standard for TB diagnosis remains the identification of *M. tuberculosis* in tissue culture, but this is time consuming and often fails. Polymerase chain reaction (PCR) is being used more frequently because of its high sensitivity and specificity.

The tuberculin skin test (TST) can be false positive as a result of previous BCG vaccination or sensitization to nontuberculous mycobacteria (such as *M. avium* and *M. scrofulaceum*) and false negative in patients with reduced cellular immunity and the elderly.

Interferon- γ release assays (IGRAs) such as T-SPOT Assay TB test (T-SPOT) and QuantiFERON-TB Gold test (QTF-G) have low false-positive rates, regardless of BCG vaccination, and high specificity for identification of *M. tuberculosis* infection. These blood tests require only one patient visit and are therefore preferred over TST.

It is imperative to search for an extracutaneous focus of infection. Contact tracing is an important component of efficient TB management. HIV testing is recommended in all patients with diagnosed or suspected TB.

The aims of treatment are to rapidly cure the patient, to reduce transmission of TB to others, and to prevent the development and transmission of drug resistance. A past history of tuberculosis should be determined, as these patients are more likely to be infected with a strain of mycobacterium that is resistant to antituberculosis drugs.

Treatment of cutaneous tuberculosis does not differ from conventional antituberculous therapy, and tuberculids generally resolve after treatment of the underlying infection. Regimens are based on controlled trials on pulmonary TB. The standard 6-month regimen for adults comprises rifampicin (10 mg/kg), isoniazid (INH) (5 mg/kg), pyrazinamide (35 mg/kg), and ethambutol (15 mg/kg) for the initial 2 months of intensive phase treatment, followed by rifampicin and INH for a further 4 months in the continuation phase, ideally in fixed-dose combinations. Daily dosing throughout treatment is preferred. Occasionally longer treatment regimens may be necessary (e.g., in HIV-positive cases). Multidrug-resistant tuberculosis should be managed at specialist centers.

Specific Investigations

- Skin biopsy for histopathology
- Culture of tissue or pus for *M. tuberculosis*
- Interferon- γ -based assays
- PCR for *M. tuberculosis* DNA in skin
- Screening for tuberculosis at other sites: chest x-ray, cultures of sputum, early morning urine, etc.
- TST
- HIV screen

Usefulness of interferon- γ release assays in the diagnosis of erythema induratum

Vera-Kellet C, Peters L, Elwood K, Dutz JP. Arch Dermatol 2011; 147: 949–52.

IGRAs confirmed the diagnosis in five patients and supported initiation of anti-TB treatment in four of five patients who had positive TST with a history of prior BCG vaccination.

Interferon- γ release assay and reverse blot hybridization assay: diagnostic role in cutaneous tuberculosis

Chung HC, Kim BK, Hong H, Wang HY, Kim Y, Lee H, et al. Acta Derm Venereol 2016; 96: 126–7.

IGRAs and the reverse blot hybridization assay (REBA) confirmed the diagnosis in seven patients, six of whom had been diagnostically challenging, with negative staining or culture from skin samples. These patients were successfully treated.

PCR based detection of mycobacteria in paraffin wax embedded material routinely processed for morphologic examination

Frevel T, Schäfer KL, Tötsch M, Böcker W, Dockhorn-Dworniczak B. Mol Pathol 1999; 52: 283–8.

PCR-based techniques are sensitive, specific, and rapid methods for the detection of mycobacteria in routinely processed, formalin-fixed, paraffin wax–embedded, histologic samples.

Papulcrotic tuberculid. Identification of *Mycobacterium tuberculosis* DNA by polymerase chain reaction

Victor T, Jordaans HF, van Niekerk DJ, Louw M, Jordaan A, Van Helden PD. Am J Dermatopathol 1992; 14: 491–5.

Mycobacterial antigens may also be detected in tuberculids using PCR.

Cutaneous tuberculosis with nonreactive PPD skin test: a diagnostic challenge

Nassif PW, Rosa AP, Gurgel AC, Campanerut PA, Fillus Neto J, Cardoso RF. An Bras Dermatol 2015; 90: 128–30.

A 63-year-old female patient with cutaneous chancre had a negative PPD despite being immunocompetent. Diagnosis was confirmed by PCR.

First-Line Therapy

• Antituberculous drugs

A

Treatment of Tuberculosis: Guidelines for National Programmes, 4th ed. Geneva: World Health Organization, 2009

New patients with pulmonary TB should receive a regimen containing 6 months of rifampicin. The essential anti-TB drugs recommended are isoniazid (H) (5 mg/kg), rifampicin (R) (10 mg/kg), pyrazinamide (Z) (25 mg/kg), streptomycin (S) (15 mg/kg), and ethambutol (E) (15 mg/kg). The recommended regimen is 2 months of HRZE followed by 4 months of HR. The WHO recommends that daily dosing throughout the duration of therapy (2HRZE/4HR) is optimal for all newly diagnosed patients with TB.

The WHO no longer recommends omission of ethambutol during the intensive phase of treatment for patients with a low risk of resistance to INH. In tuberculous meningitis, ethambutol should be replaced by streptomycin.

Comparative efficacy of drug regimens in skin tuberculosis

Ramesh V, Misra RS, Saxena U, Mukherjee A. Clin Exp Dermatol 1991; 16: 106–9.

Three antituberculous drug regimens were employed to study the response in 90 cases. The first two regimens contained rifampicin (adults 450 mg, children 15 mg/kg), INH (adults 300 mg, children 5 mg/kg), and either pyrazinamide (adults 1500 mg, children 30 mg/kg) or thiacetazone (adults 150 mg, children 4 mg/kg); the third regimen had rifampicin and INH only. The patients with lupus vulgaris and warty tuberculosis cleared with all three regimens in 4 and 5 months for localized and generalized disease, respectively. Patients with scrofuloderma responded well to both triple-drug regimens, with the skin lesions subsiding completely within 5 months in the localized and 6 months in the widespread forms of the disease. However, 9 to 10 months of treatment were necessary in the group receiving isoniazid and rifampicin.

Atypical cutaneous tuberculosis in a patient with rheumatoid arthritis treated with infliximab

Asano Y, Kano Y, Shiohara T. Acta Derm Venereol 2008; 88: 183–4.

A 73-year-old woman developed cellulitis-like cutaneous TB after infliximab initiation for rheumatoid arthritis. Quadruple therapy was started, and the lesion resolved after 5 months of treatment.

Plaques on a butcher's fingers

Arunachalam M, Scarfi F, Galeone M, Maio V, Bellandi S, Difonzo E. Arch Dermatol 2012; 148: 531–6.

A 63-year-old butcher presented with tuberculosis verrucosa cutis of two fingers of the left hand. This was successfully treated with rifampicin (450 mg/d) and isoniazid (300 mg/d) for 4 months.

Tuberculous granuloma: a rare cause of a non-healing ulcer

Graham GE, Jones R, Derry D. BMJ Case Rep 2014; pii: bcr2014205899.

A 78-year-old immunosuppressed woman presented cutaneous TB manifesting as a cystic swelling of the forehead. Because she was unable to swallow tablets, she received liquid rifampicin and liquid isoniazid for 9 months, which resulted in successful clearance.

Second-Line Therapies

• Excision	D
• Calcipotriol	E

Scrofuloderma of the lower extremity treated with wide resection: a case report and review of the literature

Connolly B, Pitcher JD Jr, Roth B, Youngberg RA, Devine J. Am J Orthop 1999; 28: 417–20.

A report of an immunocompromised patient presenting with scrofuloderma of the lower extremity. This failed to resolve with the standard antituberculous regimen consisting of four drugs: INH, rifampicin, pyrazinamide, and ethambutol for 2 months, followed by INH and rifampicin for 3 months, but was then successfully treated with wide resection under spinal anesthesia.

Lupus vulgaris of the ear lobe

Okazaki M, Sakurai A. Ann Plast Surg 1997; 39: 643–6.

A 59-year-old woman with an initial diagnosis of hemangioma had surgical treatment followed by antituberculous therapy (INH,

rifampicin, and pyridoxine for 9 months) for lupus vulgaris of the earlobe.

Lupus vulgaris responding to calcipotriol

Moriarty B, Kennedy C, Bourke JF, Fitzgibbon J. J Am Acad Dermatol 2009; 60: AB106.

A 73-year-old male with plaque form lupus vulgaris of the buttock developed drug-induced hepatitis and fulminant hepatic failure due to antituberculous medication. A 6-month trial of topical calcipotriol 50 µg/g ointment then led to resolution of the lesion without recurrence.

Urticaria and angioedema

Marcus Maurer, and Torsten Zuberbier

Treatment algorithms for chronic urticaria
The 2013 update and revision of the
EAACI/GA²LEN/EDF/WAO guideline for urticaria (1)
recommends following a three-step algorithm for the
treatment of patients with chronic urticaria (*panel a*).
During the guideline consensus conference

URTICARIA2016 on December 1, 2016, in Berlin, an update and revision of this guideline was proposed, discussed and consented (*panel b*). This takes new data on safety and efficacy into consideration and that licensed products should be preferred. The algorithm shown in panel b is pending final approval by the urticaria guideline expert panel members and the endorsing societies.

Urticaria is a frequent disease affecting up to 20% of us at least once during our lifetimes. The hallmark feature of urticaria is the wheal, which is caused by mast cell–derived mediators such as histamine that produce transient increases in the vasopermeability of cutaneous blood vessels resulting in a short-lived, superficial skin swelling. In addition to these wheals (sometimes called *hives*), many urticaria patients develop deep swellings of the dermis and subcutis, known as *angioedema*. Some urticaria patients exclusively experience angioedema, and they never have wheals. Wheals and angioedema are not pathognomonic for urticaria, that is, patients with other diseases may experience whealing or angioedema. For example, angioedema without wheals can be mediated by bradykinin independently of mast cell degranulation and histamine, and wheals also occur in patients with urticarial vasculitis or autoinflammatory syndromes, which are mediated by interleukin-1 rather than mast cell–derived histamine or bradykinin.

Urticaria

Introduction

The signs and symptoms of urticaria are brought about by the degranulation of cutaneous mast cells. Skin mast cells are preferentially localized in the vicinity of sensory nerves and small blood vessels. Their activation by certain signals, such as IgE crosslinking, can lead to their degranulation and the release of de novo synthesized and preformed mediators (e.g., histamine). These mediators induce sensory nerve stimulation (itch, burning pain); vasodilatation (flare); edema (wheal, angioedema); and the recruitment of immune cells such as neutrophils, eosinophils, and basophils.

Clinically, urticaria is characterized by the rapid development of

wheals, angioedema, or both. Wheals are associated with itching or burning as well as a flare reaction. They resolve spontaneously, usually within a few hours. In contrast, angioedemas are deeper, pronounced, and sometimes painful swellings of the lower dermis and subcutis and can also affect the mucous membranes. They are of longer duration and slower resolution than are wheals and can last for several hours to a few days.

Urticaria is either acute (less than 6 weeks' duration) or chronic. Urticaria patients develop wheals and/or angioedema spontaneously (spontaneous urticaria) or in response to a specific trigger (inducible urticaria). The specific triggers of whealing and angioedema formation in chronic inducible urticaria can be physical, for example, contact with cold or heat (cold urticaria, heat urticaria), irradiation with UV light or visible light (solar urticaria), friction (symptomatic dermographism), pressure (pressure urticaria), or vibration (vibratory angioedema). In contrast to these so-called *physical forms* of inducible urticaria, the development of signs and symptoms in the other types of inducible urticaria is triggered by skin contact with urticariogenic substances, including water (contact urticaria, aquagenic urticaria), or by active or passive overheating (cholinergic urticaria).

In chronic spontaneous urticaria, wheals occur most often at the legs and arms, whereas angioedema is most commonly localized in the face (e.g., the lips and eyes). In contrast, chronic inducible urticaria is characterized by whealing and/or angioedema formation at the skin sites that are exposed to the eliciting trigger. Disease activity and control in chronic spontaneous urticaria are assessed by the use of the urticaria activity score (UAS7), which relies on patient documentation of daily wheal numbers and itch intensity, and the urticaria control test (UCT), respectively. The UCT is a validated and reliable four-item retrospective tool to assess disease control in patients with chronic urticaria (spontaneous and inducible). Disease activity in inducible urticarias is measured by assessing trigger thresholds via provocation testing.

Important differential diagnoses of urticaria are severe allergic reactions (e.g., anaphylactic shock), where wheals and/or angioedema co-occur with systemic manifestations, urticarial vasculitis, autoinflammatory syndromes, and bradykinin-mediated angioedema (e.g., hereditary or acquired C1 inhibitor deficiency).

Management Strategy

The aim of the treatment of patients with urticaria is the elimination of signs and symptoms. This may be achieved by treating an underlying cause or condition, by avoiding eliciting triggers, by preventing mast cell degranulation, or by blocking the effects of histamine or other mast cell mediators. For the inducible urticarias, causes are largely unknown, and their triggers of wheal and/or angioedema development may be difficult or impossible for patients to avoid. All urticarias are self-limited, and very effective and safe symptomatic treatment options are available. The prevention of recurring urticaria signs and symptoms by medication that protects patients from the effects of relevant mast cell degranulating signals or of the mediators released by mast cells is, therefore, the most common approach for the management of urticaria.

Acute urticaria

Acute urticaria in most patients can be managed with oral second-generation H₁ antihistamines (sgAHs). Add-on oral glucocorticosteroids may be used for a few days for severe cases, and they can reduce disease activity and duration when given at the onset of the disease. sgAHs used in the treatment of chronic urticaria include the following:

Second-generation antihistamine	Daily standard dose
Bilastine	20 mg
Cetirizine	10 mg
Desloratadine	5 mg
Fexofenadine	180 mg
Levocetirizine	5 mg
Loratadine	10 mg
Mizolastine	10 mg
Rupatadine	10 mg

Chronic spontaneous urticaria

By taking a good history and asking the patient to keep a diary, it is often possible to identify exacerbating factors that increase disease activity, for example, stress or the intake of nonsteroidal antiinflammatory drugs. Avoiding these triggers can help to reduce disease activity. Other nonpharmacologic interventions include the avoidance of foods that contain pseudoallergens by keeping a specific

diet for 3 weeks.

Current guidelines recommend a step-up approach for the pharmacologic treatment of patients with chronic spontaneous urticaria, with standard-dosed and up-to-fourfold-dosed sgAHs followed by add-on omalizumab or ciclosporin in treatment-resistant patients. Based on the available evidence and experience, these treatment options work in most patients and should be explored before moving to other therapies.

The signs and symptoms of chronic spontaneous urticaria are largely driven by mediators released from activated skin mast cells. The most prominent one is histamine, which exerts its action via H_1 receptors on cutaneous blood vessels and nerves. The first-line pharmacologic approach for the treatment of all patients with chronic spontaneous urticaria is, therefore, the use of sgAHs at licensed doses. All sgAHs are inverse agonists that promote the inactivate state of the H_1 receptor and prevent its binding of histamine. sgAHs should, therefore, be taken regularly (i.e., every day) to prevent histamine-mediated extravasation and to protect from the development of skin lesions rather than as on-demand medication after skin lesions have already developed. sgAHs are highly selective for the H_1 receptor and are minimally or nonsedating because of their low penetration of the blood–brain barrier, an important difference to first-generation antihistamines. The use of standard-dosed sgAHs as first-line therapy of chronic spontaneous urticaria is supported by a large body of high-quality evidence for their efficacy and safety from numerous randomized controlled trials. Current guidelines recommend not using first-generation AHs routinely in the management of chronic spontaneous urticaria, as they can have anticholinergic effects, cause sedation, impair the quality of sleep, affect cognitive and psychomotor functions, and exhibit interactions with other drugs.

In patients with chronic spontaneous urticaria who continue to show signs and symptoms after 2 weeks of standard-dosed sgAH treatment, up dosing of the sgAH to up to fourfold the licensed dose should be considered. This second-line therapy, with one sgAH at a higher-than-standard dose, is preferable to combining different H_1 antihistamines at the same time in the same patient. The recommendation to updose sgAHs in treatment-resistant patients is based on several randomized controlled trials (RCTs), numerous real-life surveys, and long-standing and broad experience, all of which

support the notion that up-dosed sgAHs show higher efficacy in chronic spontaneous urticaria compared with standard-dose sgAH treatment. In general, higher-than-standard doses of sgAHs are held to be safe and well tolerated, even with long-term use. Most modern sgAHs have been described to also have antiinflammatory effects, often only at high doses. However, individual sgAHs exhibit differences in the strength of the evidence in support of their safety and efficacy when used at higher-than-standard doses. Thus responses to treatment both in terms of disease control and sedation or other possible side effects need to be monitored continuously.

Most patients with chronic spontaneous urticaria benefit from sgAH treatment, but many do not show complete control. In patients who exhibit continued recurrence of urticaria signs and symptoms after a few weeks of high-dose sgAH therapy, add-on treatment with omalizumab should be considered. The long-term use of systemic glucocorticosteroids is to be avoided, but a short course may be tried to control acute exacerbation. Omalizumab is a humanized antibody against IgE licensed for the treatment of asthma and chronic spontaneous urticaria. Recently a meta-analysis of its use in seven RCTs found omalizumab to be very safe and effective in patients with chronic spontaneous urticaria who were treatment resistant to H1 antihistamine treatment in licensed doses or up to four times the licensed dose (Zhao et al., 2016). The first RCT performed in chronic spontaneous urticaria used the omalizumab dosing regimen established for severe asthma, but subsequent trials revealed that urticaria symptoms and quality of life improved significantly with a standard dose of 150 mg or 300 mg/4 weeks omalizumab, independent of body weight or IgE serum levels. The largest decrease of disease activity and the highest number of patients with complete response were found in the 300-mg group. Similar to antihistamines, omalizumab is a symptomatic rather than a curative treatment, and the adaptation of dosing and treatment intervals to fluctuations in disease activity should be considered, based on continued monitoring of disease control and impact on patients.

The treatment of patients with chronic spontaneous urticaria with omalizumab during the past years confirms the good risk/benefit profile of this therapy seen in clinical trials. It also indicates that the onset of action of omalizumab in most patients is fast, often within a few days after the first administration, but that up to five treatments may be needed for some patients to respond. Most omalizumab-

treated patients with chronic spontaneous urticaria are able to stop all concomitant therapies and remain free of symptoms with omalizumab alone. Omalizumab appears to also be effective in chronic spontaneous urticaria patients with both wheals and angioedema, as well as in those suffering from isolated angioedema.

The use of ciclosporin as in a back-up treatment option in treatment-resistant patients is supported by the long-standing experience and evidence that this drug is effective in up to two thirds of patients. Ciclosporin is usually given over 3 to 4 months at a starting dose of 4 mg/kg/day with a fast onset of action, usually within a week, in most patients. When working with ciclosporin, its known side effects, including hypertension, hypertrichosis, increase of creatinine levels up to renal failure, and dyslipidemia, need to be considered and checked for in treated patients. Patients treated with ciclosporin should be examined and monitored before and during treatment.

Many other treatments have been used in chronic spontaneous urticaria, but either their effects have not been studied in controlled settings or the strength of the evidence in support of their use is low. Treatments that may be used in chronic spontaneous urticaria patients who are treatment resistant to sgAHs, omalizumab, and/or ciclosporin include, but are not limited to, autologous whole blood or serum therapy, azathioprine, cyclophosphamide, colchicine, dapsone, H₂ antagonists, intravenous immunoglobulins, leukotriene antagonists, methotrexate, and mycophenolate mofetil.

Chronic inducible urticaria

The treatment approaches and medications used for chronic inducible urticarias are, by and large, similar to those for chronic spontaneous urticaria. Patients can benefit from knowing what triggers their urticaria and knowing their individual trigger threshold, as this can help them to avoid situations associated with disease exacerbation. For many forms of chronic inducible urticaria, however, it is very difficult or impossible for patients to completely avoid any exposure to the eliciting trigger, for example, mechanical irritation of the skin in symptomatic dermatographism. Because of this, pharmacologic treatment is very important and needed for most patients with chronic inducible urticaria. sgAHs are the first-line treatment of choice, and doses should be increased up to fourfold in patients who

do not respond. All sgAHs are licensed for use in chronic inducible urticarias. Moreover, based on clinical experience and some studies, they are effective and safe in all forms of chronic inducible urticaria. However, for most forms of chronic inducible urticaria, no controlled studies have been performed with standard-dosed and/or higher-than-standard doses of sgAHs. Several case series and reports indicate that omalizumab is effective and safe for the treatment of patients with inducible forms of chronic urticaria, but it is not licensed for this. Treatment suggestions that are specific for individual forms or groups of chronic inducible urticaria are, in general, backed only by weak evidence or no evidence (Magerl et al., 2016). For example, in some forms of chronic inducible urticaria such as cold urticaria, solar urticaria, and cholinergic urticaria, tolerance can be induced by desensitization protocols using repeated exposure to the relevant trigger with gradually increasing strength. However, this tolerance is transient, patients usually require daily maintenance exposure, and severe side effects have been described.

Specific Investigations

Acute urticaria

- None

Chronic spontaneous urticaria

- Exclude differential diagnoses
- Check for systemic inflammation (C-reactive protein [CRP], erythrocyte sedimentation rate [ESR], differential blood count)
- Assess disease activity and control, for example, by use of the urticaria activity score (UAS7) and the urticaria control test (UCT), respectively
- In patients with uncontrolled or long-standing disease, consider underlying causes based on history and physical examination
- Consideration of histamine release assays (when available) in cases of suspected autoimmunity

Chronic inducible urticaria

- Exclude differential diagnoses
- Confirm relevance of trigger(s) by provocation testing
- Determine disease activity by assessing trigger threshold and use

of the UCT

The EAACI/GA²LEN/EDF/WAO Guideline for the definition, classification, diagnosis and management of urticaria. The 2013 revision and update

Zuberbier T, Aberer W, Asero R, Bindslev-Jensen C, Brzoza Z, Canonica GW, et al. Allergy 2014; 69: 868–87.

The definition, diagnostic testing and management of chronic inducible urticarias – update and revision of the EAACI/GA²LEN/EDF/UNEV 2016 consensus panel recommendations

Magerl M, Altrichter S, Borzova E, Giménez-Arnau A, Grattan CEH, Lawlor F, et al. Allergy 2016; 71: 780–802.

First-Line Therapy

• Second-generation H ₁ antihistamines	A
---	----------

Second-Line Therapy

• Up to fourfold standard dose second- generation H ₁ antihistamines	A
---	----------

Third-Line Therapy

• Omalizumab	A
--------------	----------

Omalizumab for the treatment of chronic spontaneous urticaria:

a meta-analysis of randomized clinical trials

Zhao Z, Ji C, Yu W, Meng L, Hawro T, Wei JF, et al. J Allergy Clin Immunol 2016; 137: 1742–50.

This meta-analysis of seven RCTs with omalizumab in CSU demonstrates that this treatment is safe and effective and that 300 mg of omalizumab every 4 weeks is the preferred dose.

Fourth-Line Therapy

• Ciclosporin	A
----------------------	----------

Cyclosporine in chronic idiopathic urticaria: a double blind, randomized, placebo-controlled trial

Vena GA, Cassano N, Colombo D, Peruzzi E, Pigatto P; NEO-I-30 Study Group. J Am Acad Dermatol 2006; 55: 705–9.

Ninety-nine patients with severe chronic urticaria were treated with ciclosporin for 16 weeks or for 8 weeks followed by 8 weeks placebo, or placebo for 16 weeks. Ciclosporin was started at a dose of 5 mg/kg and reduced in two steps to 3 mg/kg by day 28. Symptom scores improved significantly in both ciclosporin groups.

Angioedema

Introduction

In contrast to mast cell-mediated angioedema, which is a frequent feature and sign of chronic urticaria, non-mast cell-mediated angioedema is a group of diseases. These include hereditary angioedema (HAE) with or without C1 inhibitor (C1INH) deficiency, acquired C1INH deficiency, and drug-induced angioedema such as angiotensin-converting enzyme inhibitor (ACEI)-associated angioedema. Patients with these angioedema diseases, all of which are held to be bradykinin mediated, usually do not exhibit wheals.

Two major forms of HAE, both of them rare, have been described:

HAE with C1INH deficiency, subclassified as type I and type II based on low antigenic and functional C1INH levels, respectively, and HAE with normal C1INH levels, with or without mutations in Hageman factor (coagulation factor XII). Angioedema attacks in all HAE patients are held to be due to the enhanced generation of bradykinin. The group of acquired forms of non-mast cell mediator-mediated angioedema includes those that are due to acquired C1INH deficiency (e.g., increased catabolism of C1INH) and angioedema due to certain drugs, mainly ACEIs. As in HAE, attacks of patients with these forms of angioedema are linked to elevated bradykinin levels.

In patients with HAE due to C1INH deficiency, recurrent angioedema attacks primarily involve the hands and feet, the abdomen, the face, the oropharynx, or a combination of these. HAE patients often experience prodromal symptoms (e.g., erythema marginatum). Typical HAE attacks progress for several hours and then slowly resolve over many hours to several days. Attacks involving the extremities and abdomen are the most common, and attacks of the oropharynx are the most dangerous, with a significant risk of mortality due to suffocation. In comparison, HAE with normal C1INH is more likely to affect females, to first occur after puberty, and to come with fewer attacks. Triggers of attacks are common and similar in all forms of HAE and include trauma, increased estrogen levels, and stress.

Attacks in patients with angioedema due to acquired C1INH deficiency are similar to those of HAE patients, but the former show a later age of onset and no family history. Attacks in patients with ACEI-induced angioedema typically affect the face, especially the lips and tongue. The time to onset of angioedema attacks after the start of ACEI treatment is usually less than 1 month, but in one of four affected patients it is greater than 6 months, and up to 10 years in some patients.

The diagnosis of bradykinin-mediated angioedema requires a thorough history, exclusion of differential diagnoses (especially chronic urticaria), and laboratory testing for C1INH deficiency. Angioedema in patients taking an ACEI is due to the ACEI until or unless proven otherwise.

Management Strategy for Bradykinin-

Mediated Angioedema

The management of HAE with C1INH deficiency consists of the avoidance of known triggers of attacks and pharmacotherapy, that is, the use of on-demand treatment for attacks, their prevention by prophylactic treatment, or both. Today, five highly effective and safe drugs are available for the on-demand treatment of attacks: three different C1INHs (two plasma-derived and one recombinant), as well as icatibant, a selective bradykinin B2 receptor antagonist, and ecallantide, which inhibits plasma kallikrein, the protease that cleaves kininogen and generates bradykinin. Patients with HAE due to C1INH deficiency may also require prophylaxis. Preprocedural prophylaxis is usually done with C1INH with the aim to protect patients from attacks that occur in response to unavoidable triggers such as dental work or surgery. Long-term prophylaxis, that is, the regular use of medication to prevent angioedema attacks, should be considered in all HAE patients with C1INH deficiency, especially in those with high attack frequency and severity or limited access or response to on-demand treatment. C1INH is the preferred medication for long-term prophylaxis. Patients with HAE and normal C1INH, as well as patients with acquired bradykinin-mediated angioedema, can also benefit from on-demand treatment with C1INH or icatibant. Importantly, the standard treatment for attacks in patients with mast cell mediator-mediated angioedema such as glucocorticosteroids or H₁ antihistamines does not have any beneficial effect on HAE attacks and should not be used as on-demand medication for the treatment of bradykinin-mediated angioedema attacks.

Varicella

John Berth-Jones

Varicella, or chickenpox, is the exanthematic illness caused by infection with the herpesvirus varicella zoster (VZV). Varicella has a typical incubation period of 10 to 14 days, spreading by direct person-to-person contact or by airborne droplets. The disease is infectious from 48 hours before the rash appears until the vesicles crust.

Varicella occurs most commonly in young children. Systemic symptoms are usually mild, although complications may occur. In

adolescents, adults, and immunocompromised individuals of any age it is a more severe disease with a higher complication rate. Treatment is most commonly recommended in this group of individuals. Potential complications include secondary bacterial infection of the skin, bacterial pneumonia, and varicella pneumonitis. Rare complications of varicella include aseptic meningitis, encephalitis, cerebellar ataxia, myocarditis, corneal lesions, nephritis, arthritis, acute glomerulonephritis, Reye syndrome, bleeding diathesis, and hepatitis. Delayed complications include vasculopathy, which may resemble giant cell arteritis, and herpes zoster (shingles). The latter is the subject of a separate chapter.

Management Strategy

In the United States, a two-dose live attenuated *vaccine* is recommended for all healthy persons who have not had varicella. The first dose is administered at age 12 to 15 months and the second at 4 to 6 years. A second dose catch-up vaccination is recommended for individuals of all ages who have previously received one dose. Postexposure immunization may also be effective for household contacts if given within 3 days of the appearance of the rash in the index case. In the UK, routine vaccination is not recommended, except for nonimmune health care workers and other carers who are in frequent contact with individuals (mainly immunocompromised patients) who would be especially vulnerable to the infection, the purpose being to protect these vulnerable individuals.

In **healthy children** below the age of 12 years, *symptomatic treatment* is all that is generally required. *Acetaminophen* (*paracetamol*) is suitable. Aspirin should be avoided because of the risk of Reye syndrome. If a child is the second affected case in a family the illness can run a more severe course, and antiviral therapy should be considered. Oral *aciclovir* is the antiviral of choice and should be started within 24 hours of the rash developing.

In **healthy adolescents and adults**, *oral aciclovir* commenced within 24 hours of development of the rash has been shown to be beneficial. Heavy smokers and people with chronic lung disease are at greater risk of developing complications, particularly varicella pneumonitis. Treatment with aciclovir should be given if they are seen within 24 hours of the rash developing. There is no evidence confirming significant benefit if treatment is started after 24 hours in cases where

infection is following the normal course and there are no complications. These patients should be treated symptomatically and advised to return promptly if they deteriorate. Patients with complications require hospital assessment.

Pregnant women are more likely to develop severe or complicated disease. Those who are not immune to varicella should avoid contact with varicella and zoster, and if this occurs they should report the contact immediately. Nonimmune pregnant women who have had contact with a person with varicella should receive specific *varicella zoster immune globulin (VZIG)*. VZIG is effective up to 10 days after contact. This has been shown to prevent varicella or modify disease severity. It also reduces the risk of fetal transmission if disease develops. Fetal infection between 3 and 28 weeks' gestation may cause the fetal varicella syndrome (including developmental abnormalities of the eyes and central nervous system). This occurs in an estimated 0.91% of pregnancies complicated by chickenpox during the first 20 weeks of gestation. The risk is probably greatest when infection occurs between 13 and 20 weeks. During the first trimester the use of *aciclovir* carries a theoretical risk of possible teratogenesis, although it is not a recognized teratogen. Beyond 20 weeks' gestation, oral aciclovir can be unequivocally recommended if the patient is seen within 24 hours of the onset of the rash. Pregnant women who are smokers, have chronic lung disease, are taking steroids, or are in the latter half of pregnancy are at greater risk of developing systemic symptoms. *Hospitalization* should be considered in late pregnancy and in women with chest or neurologic symptoms, a hemorrhagic rash, bleeding, or very severe disease with a dense rash and mucosal lesions.

Neonates whose mothers had varicella 7 days before to 7 days after delivery should be given prophylaxis with VZIG. Neonates with varicella whose mothers developed varicella within 7 days before delivery may develop severe disease and should be treated with intravenous *aciclovir*. Treatment should also be considered within 48 hours of development of the rash in other infants with congenital varicella (rash within 16 days of delivery) and severe clinical disease.

Immunocompromised individuals exposed to varicella should be given *prophylactic VZIG*. It is most effective when given within 72 hours but may still modify the disease if given up to 10 days after exposure. Those who develop varicella, including those on oral corticosteroids or with a history of oral corticosteroid intake for more

than 3 weeks in the preceding 3 months, should be admitted to the hospital and treated with *intravenous aciclovir*, as they are at risk of severe disease and complications. Resistance to aciclovir can occur in immunocompromised individuals after long-term aciclovir therapy. In patients with proven aciclovir-resistant VZV strains, intravenous *foscarnet* provides an alternative.

Newer anti-VZV drugs have been developed. These include *valaciclovir*, *famciclovir*, and *brivudin*, although they are currently only licensed for use in herpes zoster.

Specific Investigations

- Virology on vesicle fluid
- Serology on acute and convalescent sera

The virus can be identified by electron microscopy, immune electron microscopy, tissue culture or shell viral culture, immunofluorescence, immunostaining, or detection of viral DNA by PCR.

First-Line Therapies

• Symptomatic therapy	C
• Aciclovir	A

Aciclovir for treating varicella in otherwise healthy children and adolescents

Klassen TP, Belseck EM, Wiebe N, Hartling L. Cochrane Database Syst Rev 2004; CD002980.

Aciclovir initiated within 24 hours after rash onset shows a therapeutic benefit in reducing the length of time with fever and the maximum number of lesions in immunocompetent children. Symptomatic treatment with analgesics and topical agents such as

calamine lotion or crotamiton cream and daily baths are all that is required in most children.

When required, aciclovir is the antiviral of choice. It is usually given orally. In children up to 12 years of age it is given at a dose of 20 mg/kg 6-hourly (to a maximum of 800 mg/dose) for 5 days. In adolescents and adults the dose is 800 mg five times daily for 7 days. Aciclovir is given intravenously in severe disease and in immunocompromised individuals.

Treatment of adult varicella with oral acyclovir: a randomized, placebo-controlled trial

Wallace MR, Bowler WA, Murray NB, Brodine SK, Oldfield EC III. Ann Intern Med 1992; 117: 358–63.

A study of 148 evaluable military personnel hospitalized for varicella and treated with either aciclovir 800 mg orally five times per day for 7 days or placebo. Patients treated within 24 hours of onset of the rash had fewer lesions and shorter time to crusting. Treatment after 24 hours had no effect.

Combining corticosteroids and acyclovir in the management of varicella pneumonia: a prospective study

Anwar SK, Masoodi I, Alfaifi A, Hussain S, Sirwal IA. Antivir Ther 2014; 19: 221–4.

A prospective study of 32 adult cases treated with an intravenous injection of aciclovir (10 mg/kg) every 8 hours for 4 to 10 days and of corticosteroids (100 mg hydrocortisone) every 8 hours for 5 days, supporting the use of this treatment combination. Resolution was achieved in 31 cases, and a single fatality occurred.

Second-Line Therapies

• Foscarnet	D
• Famciclovir	C
• Valaciclovir	D
• Valganciclovir	E

Foscarnet therapy in five patients with AIDS and acyclovir resistant varicella zoster virus infection

Safrin S, Berger TG, Wolfe PR, Wosby CB, Mills J, Biron KK. Ann Intern Med 1991; 115: 19–21.

Five patients with AIDS and aciclovir-resistant VZV were treated with foscarnet. Four had healing of the lesions and negative cultures during therapy. Fluorescent antigen testing remained positive in two patients: one healed completely, but the other had concomitant clinical failure of therapy.

Foscarnet is used in patients who have developed resistance to aciclovir. The dose is 40 mg/kg 8-hourly in 1-hour transfusions for 10 days.

Pharmacokinetics and safety of famciclovir in children with herpes simplex or varicella-zoster virus infection

Sáez-Llorens X, Yogev R, Arguedas A, Rodriguez A, Spigarelli MG, De León Castrejón T, et al. Antimicrob Agents Chemother 2009; 53: 1912–20.

After 7 days on an oral regimen VZV disease had resolved in 49 of 53 children. Doses were adjusted according to body weight (BW) using a nonlinear 8-point scale. The mean BW-adjusted daily dose was 40.8 mg/kg for 1- to <2-year-olds, 40.6 mg/kg for 2- to <6-year-olds, and 35.5 mg/kg for 6- to ≤12-year-olds, divided into three doses.

Varicella in a pediatric heart transplant population on nonsteroid maintenance immunosuppression

Dodd DA, Burger J, Edwards KM, Dummer JS. Pediatrics 2001; 108: E80.

Six of 14 pediatric heart transplant patients with varicella were treated with oral valaciclovir, dose range 61 to 88 mg/kg/day, for 7 days.

Complete remission of VZV reactivation treated with valganciclovir in a patient with total lymphocyte depletion and acute kidney injury after allogeneic bone marrow transplantation

Maximova N, Antonio P, Marilena G, Rovere F, Tamaro P. APMIS 2015; 123: 77–80.

Pregnancy

Chickenpox in pregnancy

Green-top Guideline No. 13. Royal College of Obstetricians and Gynecologists. January 2015.

<https://www.rcog.org.uk/globalassets/documents/guidelines/gtg13.pdf>

VZIG is recommended for postexposure prophylaxis. Oral aciclovir is recommended if patients present within 24 hours of the rash and are at more than 20 weeks' gestation. Use of aciclovir before 20 weeks should also be considered.

Management of varicella infection (chickenpox) in pregnancy

Shrim A, Koren G, Yudin MH, Farine D; Maternal Fetal Medicine Committee. J Obstet Gynaecol Can 2012; 34: 287–92.

Varicella immunization is recommended for all nonimmune women as part of prepregnancy and postpartum care. Varicella vaccination should not be administered in pregnancy. However, termination of pregnancy should not be advised because of inadvertent vaccination during pregnancy. The antenatal varicella immunity status of all pregnant women should be documented by history of previous infection, varicella vaccination, or serology. All nonimmune pregnant women should be informed of the risk of varicella infection to themselves and their fetuses. They should be instructed to seek medical help after any contact with a person who may have been contagious. In the case of a possible exposure to

varicella in a pregnant woman with unknown immune status, serum testing should be performed. If results are negative or unavailable within 96 hours from exposure, VZIG should be administered. Women who develop varicella infection in pregnancy need to be made aware of the potential adverse maternal and fetal sequelae, the risk of transmission to the fetus, and the options available for prenatal diagnosis. Detailed ultrasound and appropriate follow-up are recommended for all women who develop varicella in pregnancy to screen for fetal harm. Women with significant (e.g., pneumonitis) varicella infection in pregnancy should be treated with oral antiviral agents (e.g., aciclovir 800 mg five times daily). In cases of progression to varicella pneumonitis, maternal admission to hospital should be seriously considered. Intravenous aciclovir can be considered for severe complications in pregnancy (oral forms have poor bioavailability). The dose is usually 10 to 15 mg/kg or 500 mg/m² IV every 8 hours for 5 to 10 days for varicella pneumonitis, and it should be started within 24 to 72 hours of the onset of rash. Neonatal health care providers should be informed of peripartum varicella exposure in order to optimize early neonatal care with VZIG and immunization. VZIG should be administered to neonates whenever the onset of maternal disease is between 5 days before and 2 days after delivery.

Prophylaxis

• Vaccines	A
• Varicella zoster immune globulin	B
• Intravenous immunoglobulin	C
• Aciclovir	B

SAGE working group on varicella and herpes zoster vaccines:

background paper on varicella vaccine SAGE review 2015

http://www.who.int/immunization/sage/meetings/2014/april/1_SAGE_

The review concludes “There is strong scientific evidence that varicella vaccine is safe and effective in preventing varicella related morbidity and mortality in immunocompetent individuals.”

Introduction of varicella vaccination in the United States and elsewhere has been followed by reduced incidence and morbidity in all age groups, apparently indicating significant benefits from “herd immunity.”

Use of combination measles, mumps, rubella, and varicella vaccine: recommendations of the Advisory Committee on Immunization Practices (ACIP)

Marin M, Broder KR, Temte JL, Snider DE, Seward JF; Centers for Disease Control and Prevention (CDC). MMWR Recomm Rep 2010; 59: 1-12.

Combined vaccination with measles, mumps, and rubella vaccine (MMRV) is generally preferred, except for initial dosing before 48 months of age (as there appears to be a slightly increased risk of febrile seizure in this age group associated with the use of quadruple vaccine for the first dose).

A varicella outbreak in a school with high one-dose vaccination coverage, Beijing, China

Lu L, Suo L, Li J, Zhai L, Zheng Q, Pang X, et al. Vaccine 2012; 30: 5094–8.

Of the 951 students, 916 had received one dose of varicella vaccine, and only 2 had received two doses before the outbreak. A total of 87 cases occurred, but 95% had mild disease. Single-dose varicella vaccination was 89% effective in preventing any varicella and 99% in preventing moderate/severe varicella.

Single-dose vaccination does not prevent outbreaks but probably protects against severe disease.

Vaccines for postexposure prophylaxis against varicella (chickenpox) in children and adults

Macartney K, Heywood A, McIntyre P. Cochrane Database Syst Rev 2014; 6: CD001833.

Three small studies suggest vaccines administered within 3 days of household exposure reduce infection rates and severity.

Varicella vaccination in the immunocompromised

Malaiya R, Patel S, Snowden N, Leventis P. Rheumatology 2015; 54: 567–9.

A review of the risks from varicella in patients receiving immunosuppressive medication and the diverse recommendations regarding vaccination of this group. The authors recommend that the immune status of patients be established, and nonimmune (varicella naïve) patients should be vaccinated at least 2 weeks before commencing immunosuppressive treatment if the delay is considered tolerable. Use of varicella or zoster vaccines is not recommended in naïve patients who are already immunosuppressed.

Updated recommendations for use of VariZIG—United States, 2013

Centers for Disease Control and Prevention (CDC). Morb Mortal Wkly Rep 2013; 62: 574–6.

The CDC recommends administration of VZIG as soon as possible after exposure to VZV and within 10 days for people without evidence of immunity to varicella who are at high risk from varicella, who have been exposed to varicella or zoster, and for whom varicella vaccine is contraindicated. High-risk groups include immunocompromised patients, newborn infants whose mothers have signs and symptoms of varicella around the time of delivery (i.e., 5 days before to 2 days after), hospitalized premature infants born at ≥ 28 weeks of gestation whose mothers do not have evidence of immunity to varicella, hospitalized premature infants born at < 28 weeks of gestation or who weigh ≤ 1000 g at birth, regardless of their mothers' evidence of immunity to varicella, and pregnant women without evidence of immunity.

Intravenous immunoglobulin prophylaxis in children with acute leukemia following exposure to varicella

Chen SH, Liang DC. Pediatr Hematol Oncol 1992; 9: 347–51.

Five children with leukemia received a single dose (200 mg/kg) of IVIG within 3 days of exposure to varicella. None developed the infection.

IVIG appears to be an effective and safe alternative when VZIG is unavailable.

Postexposure prophylaxis of varicella in family contact by oral

acyclovir

Asano Y, Yoshikawa T, Suga S, Kobayashi I, Nakashima T, Yazaki T, et al. J Pediatr 1993; 92: 219–22.

Twenty-five children were treated with oral aciclovir 40 or 80 mg/kg daily in four divided doses, 7 to 9 days after household exposure to varicella. Twenty-five age-matched control subjects who had been exposed but did not receive treatment were also followed. Twenty of the 25 treated subjects were protected from disease, but 4 of them failed to seroconvert. All 25 controls developed varicella.

Although its efficacy is not as well established as that of VZIG, oral aciclovir also seems likely to be effective in postexposure prophylaxis. It is given approximately 9 days after exposure for 1 week and may abort the disease or reduce its severity.

Antiviral prophylaxis and treatment in chickenpox. A review prepared for the UK Advisory Group on Chickenpox on behalf of the British Society for the Study of Infection

Ogilvie MM. J Infect 1998; 36: 31–8.

A review of the use of VZIG, live attenuated varicella vaccine, and aciclovir. Oral aciclovir is only considered effective if begun within 24 hours of rash onset. It is recommended for treatment of varicella in otherwise healthy adults and adolescents but not for routine use in children under 13 years of age unless they are sibling contacts or have other medical conditions. Aciclovir has a high therapeutic index and good safety profile, but caution is advised with use in pregnancy.

Prophylactic role of long-term ultralow-dose acyclovir for varicella zoster virus disease after allogeneic hematopoietic stem cell transplantation

Kawamura K, Wada H, Yamasaki R, Ishihara Y, Sakamoto K, Ashizawa M, et al. Int J Infect Dis 2014; 19: 26–32.

A study of 141 patients treated prophylactically with aciclovir 200 mg daily for up to a year. Discontinuation of the drug was followed by a pronounced increase in frequency of VZV disease.

Viral exanthems

rubella, roseola, rubeola, and
enteroviruses

Julia A. Siegel, Julia O. Baltz, and Karen Wiss

Rubella

Rubella (German measles, 3-day measles) is usually a mild disease of

low-grade fever, generalized erythematous macules and papules, and generalized lymphadenopathy. It is caused by an enveloped RNA virus of the *Togaviridae* family.

Management Strategy

In children, there is typically no prodrome. In adolescents and adults, a prodrome of fever, malaise, sore throat, nausea, anorexia, and generalized lymphadenopathy is common. The erythematous pink macules and papules start on the face and neck and spread down and out in a centrifugal fashion over 1 to 2 days, disappearing in 2 to 3 days. Forchheimer spots, an enanthem consisting of petechiae on the hard palate, may accompany the rash.

Rubella is a self-limited illness. The treatment is generally *supportive*. Teenagers and adults may experience transient polyarthralgia and polyarthritis. Thrombocytopenia and encephalitis are extremely rare complications. During the first trimester of pregnancy, maternal rubella can result in fetal death or congenital rubella syndrome. The main fetal anomalies include ophthalmic disease (cataracts, glaucoma, microphthalmia, and chorioretinitis), sensorineural deafness, cardiac abnormalities (patent ductus arteriosus, atrial septal defects, ventricular septal defects), pulmonic stenosis, and blueberry muffin lesions (extramedullary hematopoiesis). Survivors of congenital rubella have a higher risk of developmental delay, including autism.

It can be difficult to distinguish rubella from other viral exanthems, in particular enteroviruses. Rubella also mimics measles, parvovirus B19, human herpes virus (HHV)-6, and arboviruses. It is essential to differentiate infection among these viruses during pregnancy. Virus identification by culture is available. In congenital infections, rubella can be isolated from the blood, urine, cerebrospinal fluid, and the posterior pharynx. In postnatal infections, the virus is harbored in the nasopharynx, and the timing of specimen collection is crucial, as samples are only virus positive on the first day of rash through 7 to 10 days afterward. Amplification is accomplished by reverse transcription polymerase chain reaction (RT-PCR). Viral serology is also available for diagnosis, but IgM is only present in 50% of samples on the first day of rash, with levels peaking 5 days later. Both serum IgM and seroconversion of convalescent IgG with a fourfold increase in titer suggest recent infection. A more reliable diagnosis is obtained

by both RT-PCR and serology, which can detect virus on day 0 of rash eruption. Avidity tests may help determine timing of infection, as low-avidity antirubella IgG is associated with recent infection. Microarray technology is a cheap and promising future methodology for diagnosis of acute infection. Children with rubella should be *excluded from school for 7 days after onset of the rash*. Rubella vaccine is recommended in combination with the measles and mumps vaccine, with or without the varicella vaccine (MMR or MMRV), at 12 to 15 months of age with a second dose at 4 to 6 years. However, an increased risk of febrile seizures has been reported with the combination MMRV vaccine. Postpubertal females can be tested for rubella IgG and vaccinated if necessary. The vaccine contains live virus and should not be given to pregnant women.

Specific Investigations

- Viral culture
- Serology (acute IgM or acute and convalescent IgG)
- PCR

Diagnosis of recent primary rubella virus infections: significance of glycoprotein-based IgM serology, IgG avidity and immunoblot analysis

Wandinger KP, Saschenbrecker S, Steinhagen K, Scheper T, Meyer W, Bartelt U, et al. J Virol Methods 2011; 174: 85–93.

The rubella IgM positive predictive value has decreased with high vaccination and seroprevalence rates in the United States. It is important to distinguish IgM reactivity due to primary rubella infection from IgM reactivity due to persistence, reinfection, polyclonal B-cell stimulation, and cross-reactivity. This may be done using specific IgG avidity and immunoblot analyses.

First-Line Therapies

• Antipyretics: acetaminophen (paracetamol), ibuprofen	E
• Analgesics: nonsteroidal antiinflammatory drugs	E
• School avoidance for 7 days	A
• Immunization	A

Rubella

Lambert N, Strebel P, Orenstein W, Icenogle J, Poland GA. Lancet 2015; 385: 2297–307.

Since the advent of the national rubella vaccination program, rubella virus is no longer endemic in the United States. From 2000 to 2012, rubella cases decreased by 99.9% in the Americas, from 39,228 to only 21.

Post-exposure passive immunisation for preventing rubella and congenital rubella syndrome

Young MK, Cripps AW, Nimmo GR, van Driel ML. Cochrane Database Syst Rev 2015.

Polyclonal immunoglobulins may prevent rubella up to 5 days after exposure, with dose-dependent effectiveness. Evidence of congenital rubella prevention with polyclonal immunoglobulins is inconclusive.

Roseola

Roseola infantum (exanthem subitum, sixth disease) is a disease of high fever in a well-appearing child with eruption of pink macules and papules upon defervescence. It is caused by infection with HHV-6 (which includes HHV-6A and HHV-6B species) or HHV-7.

Management Strategy

Roseola is an illness of children between 6 and 36 months of age. The first sign of illness is a high fever ($>39.5^{\circ}\text{C}$) that persists for 3 to 7 days, followed by an exanthem that spreads centrifugally from the neck, lasting hours to days. Typically, no treatment is necessary and the illness resolves in a few days. Febrile seizures are common in infants during the febrile phase, often requiring emergency room

care.

Identification of HHV-6 or -7 is difficult because most infections are asymptomatic. Culture from peripheral blood is available in specialized facilities, but is of limited use due to slow turnover. High population seroprevalence (~95%) also renders serology less useful. Seroconversion of convalescent IgG with a fourfold increase in titer is more indicative of acute infection; however, there is considerable antibody cross-reactivity between HHV-6, -7, and cytomegalovirus (CMV). Viral DNA detection by nucleic acid amplification of whole blood, serum, or plasma is the current method of diagnosis, though standardized methods of measurement are yet to be determined. PCR alone cannot reliably distinguish between active and latent infection; a multiple assay approach is more sensitive and specific. Antibody avidity can help clarify timing, as high avidity indicates at least 6 weeks since infection. Additionally, two new RT-qPCR assays have been developed to detect specific viral transcripts expressed during multiplication, allowing for better differentiation between active and latent infection. Digital droplet PCR is useful for viral quantification and identification of chromosomally integrated HHV-6.

Most individuals harbor HHV-6 and -7 in their saliva, whereas only 1% of the population carries chromosomally integrated viral DNA. In the immunocompromised, viral reactivation frequently causes severe disease such as fever, bone marrow suppression, hepatitis, pneumonia, lymphoproliferative disorders, and encephalitis. In these patients, *ganciclovir* and *foscarnet* are first-line treatments, although conflicting evidence exists regarding survival benefit. Foscarnet has shown prophylactic efficacy in stem cell transplant patients. In vitro studies show that ganciclovir, cidofovir, and foscarnet inhibit HHV-6 and -7 replication. Individual case reports have suggested benefit from these agents in immunocompetent patients with end organ disease. Infection with HHV-6 can be associated with a severe course of drug-induced hypersensitivity syndrome (DIHS), also known as drug reaction with eosinophilia and systemic symptoms (DRESS).

Specific Investigations

- No investigation is required routinely
- HHV-6 serology (acute IgM or acute and convalescent IgG)
- PCR

First-Line Therapy

- | | |
|---|---|
| • Antipyretics (acetaminophen, ibuprofen) | E |
|---|---|

Second-Line Therapies

• Ganciclovir	D
• Foscarnet	D

High-dose ganciclovir in HHV-6 encephalitis of an immunocompetent child

Olli-Lähdesmäki T, Haataja L, Parkkola R, Waris M, Bleyzac N, Ruuskanen O. *Pediatr Neurol* 2010; 43: 53–6.

Though antiviral treatment is usually reserved for immunocompromised patients, high-dose ganciclovir (18 mg/kg/day) was safe and efficacious in this 15-month-old with HHV-6 encephalitis.

Human herpesvirus type 6 and human herpesvirus type 7 infections of the central nervous system

Dewhurst S. *Herpes* 2004; 11: 105A–11A.

Ganciclovir and foscarnet may be used for managing HHV-6–related disease. Ganciclovir, but not foscarnet, may be useful for HHV-7–related illness.

Safety of pre-engraftment prophylactic foscarnet administration after allogeneic stem cell transplantation

Ishiyama K, Katagiri T, Ohata K, Hosokawa K, Kondo Y, Yamazaki H,

et al. *Transpl Infect Dis* 2012; 14: 33–9.

In 10 stem cell transplant patients, prophylactic foscarnet reduced the risk of HHV-6 or -7–associated encephalitis but was unable to prevent HHV-6 reactivation.

Diagnostic clues to human herpesvirus 6 encephalitis and Wernicke encephalopathy after pediatric hematopoietic cell transplantation

Sadighi Z, Sabin ND, Hayden R, Stewart E, Pillai A. *J Child Neurol* 2015; 30: 1307–14.

Rapid treatment with intravenous foscarnet or ganciclovir in HHV-6 encephalitis after hematopoietic cell transplantation may optimize neurologic recovery. Foscarnet has been shown to be effective against both HHV-6A and HHV-6B, whereas ganciclovir has only been shown to work against HHV-6B.

Human herpesvirus types 6 and 7 infection in pediatric hematopoietic stem cell transplant recipients.

Fule Robles JD, Cheuk DK, Ha SY, Chiang AK, Chan GC. *Ann Transplant* 2014; 19: 269–76.

Multiple studies have shown that ganciclovir and foscarnet resolve viremia, but may not improve survival. If these medications fail in severe HHV-6 or -7 infections, cidofovir may be tried. However, cidofovir has poor cerebrospinal fluid (CSF) penetration and may not be effective in treating herpes virus encephalopathy.

Rubeola

Rubeola (measles) is a systemic illness with fever, cough, coryza, conjunctivitis, erythematous macules and papules, and Koplik spots. It is caused by infection with the measles virus, an enveloped RNA virus of the *Paramyxoviridae* family.

Management Strategy

The measles rash begins along the hairline and behind the ears and spreads down the body. It is the prototype of the “morbilliform eruption.” Koplik spots, the pathognomonic enanthem of clustered white dots on the buccal mucosa, precede the rash by approximately 2

days. It is important to distinguish the measles rash from drug eruptions, Kawasaki disease, and other viral infections, in particular exanthems from enteroviruses and adenoviruses. Complications include pneumonia, croup, diarrhea, encephalitis, and death. Subacute sclerosing panencephalitis due to persistent measles infection is a rare degenerative neurologic disease that can occur years after original infection.

Rapid diagnosis by immunofluorescence of desquamated nasal mucosal cells is available. Both serum IgM at the onset of rash and seroconversion of convalescent IgG with a fourfold increase in titer suggest recent infection. RT-PCR of nasopharyngeal secretions, oral fluids, or serum provides the most reliable diagnostic method of acute infection. Oral fluid assays may represent the future of measles detection, as sampling is painless and cost effective.

Children with measles should be *isolated for 4 days after rash eruption*, and physicians should *notify* the appropriate monitoring authorities. Measles *vaccine* contains live virus and is recommended as part of the MMR or MMRV regimen at 12 to 15 months with a second dose at 4 to 6 years of age. It can also be given as a measles-only formulation.

Individuals with poor nutritional status are at greatest risk for complications from measles. *Dietary supplementation with vitamin A* may reduce the morbidity and mortality of the disease. Supplementation should be given to children 6 to 24 months of age who are hospitalized for measles complications. Any child with measles and compromised immune function, malnutrition, vitamin A deficiency, or recent travel to high-measles-mortality areas is also a candidate for treatment. The World Health Organization recommends two doses of 50,000 IU for infants <6 months, 100,000 IU for children 6 to 12 months, and 200,000 IU for individuals >1 year. A recent meta-analysis demonstrated that at least two doses of 200,000 IU for children >1 year and 100,000 IU for infants were found to reduce measles mortality by approximately 60%. *Immunoglobulin prophylaxis* can prevent or modify disease within 7 days of exposure. It is recommended for susceptible household contacts, especially for infants, pregnant women, or immunocompromised individuals.

Measles virus is susceptible to *ribavirin* in vitro, although its clinical efficacy is questionable. It has been given intravenously and intranasally to treat immunocompromised children with severe illness. Novel nonnucleoside inhibitors of measles RNA polymerase, such as ERDRP-0519, which targets morbillivirus RNA-dependent

RNA polymerase, are in development and show promise.

Measles is a notifiable disease in many jurisdictions, including the UK and United States.

Specific Investigations

- Immunofluorescence of nasal mucosal cells
- Serology (acute IgM or acute and convalescent IgG)
- Viral culture
- PCR

Assessment of measles diagnostic from gingival fluid in Côte d'Ivoire

Bénié BVJ, Attoh-Touré H, Aka LN, Fofana N, Tiembré I, Dagnan NS. Bull Soc Pathol Exot 2015; 108: 262–4.

Oral fluid demonstrates equal diagnostic ability compared with the gold standards of serum enzyme-linked immunosorbent assay (ELISA). In addition, oral fluid collection is painless, cost effective, and does not require complicated technical skills.

First-Line Therapies

• Antipyretics: acetaminophen, ibuprofen	E
• Measles vaccine (prevention and after exposure)	A

Progress toward regional measles elimination worldwide, 2000–2013

Centers for Disease Control and Prevention. MMWR 2014; 63: 1034–8.

From 2000 to 2012, an increase in routine vaccination and supplementary immunization activities led to a 77% decrease in reported annual measles incidence worldwide and a 78% decrease in measles mortality (from 562,400 to 122,000), preventing an estimated 13.8 million deaths.

Measles cases exceed 100 in US outbreak

McCarthy M. BMJ 2015; 350: h622.

In 2014, 644 measles cases were reported in the United States, a record high since measles elimination in 2000, and over 100 cases were reported in 2015. The majority of infected individuals have not been vaccinated. High rates of vaccine refusal cluster geographically, where parents are concerned about the safety of vaccines.

Effectiveness of measles vaccination for control of exposed children

Barrabeig I, Rovira A, Rius C, Muñoz P, Soldevila N, Batalla J, et al. *Pediatr Infect Dis J* 2011; 30: 78–80.

There is considerable debate about the efficacy of postexposure prophylaxis with measles vaccine. This study demonstrated that vaccination within 72 hours of exposure prevented 90.5% of disease cases.

Second-Line Therapies

• Oral vitamin A	A
• Immunoglobulin prophylaxis	A
• Ribavirin and IFN- α	D

Effectiveness of measles vaccination and vitamin A treatment

Sudfeld CR, Navar AM, Halsey NA. *Int J Epidemiol* 2010; 39: i48–55.

One dose of measles vaccine is 85% effective in preventing measles disease, whereas a second dose is estimated to be 98.1% to 100% effective. Vitamin A treatment demonstrated a 62% reduction in measles mortality with two doses of 200,000 IU in children >1 year and 100,000 IU for infants.

An assessment of measles vaccine effectiveness, Australia, 2006–2012

Pillsbury A, Quinn H. *WPSAR* 2015; 6: 43–50.

One dose of measles vaccine is 96.7% effective in preventing measles disease, whereas a second dose is estimated to be 99.7% effective.

Post-exposure passive immunisation for preventing measles

Young MK, Nimmo GR, Cripps AW, Jones MA. Cochrane Database Syst Rev 2014: CD010056.

Passive immunization with immunoglobulins in nonimmune individuals decreases the risk of measles by 83% and decreases mortality by 76% when administered within 7 days of exposure.

Measles control—can measles virus inhibitors make a difference?

Plemper RK, Snyder JP. Curr Opin Investig Drugs 2009; 10: 811–20.

Ribavirin and IFN- α are used clinically for severe cases of measles infection, though their efficacy and side effect profiles are unfavorable. A novel antiviral agent is greatly needed, and novel nonnucleoside inhibitors of measles RNA polymerase show potential.

An orally available, small-molecule polymerase inhibitor shows efficacy against a lethal morbillivirus infection in a large animal model

Krumm SA, Yan D, Hovingh ES, Evers TJ, Enkirch T, Reddy GP, et al. Sci Transl Med 2014; 6: 232ra52.

A novel, orally available, antimorbillivirus drug, ERDRP-0519, which targets morbillivirus RNA-dependent RNA polymerase, has recently been reported as capable of curing a lethal morbillivirus infection when administered at the first onset of viremia. This drug was efficacious against measles virus in vitro and against the closely related canine distemper virus (CDV) in vivo in ferrets.

Enteroviruses

Enteroviruses are a group of nonenveloped RNA viruses that include coxsackieviruses A and B, enteroviruses 68 to 71, echoviruses, and polioviruses. As polio has been eliminated in the United States, nonpolioviruses are the main concern. There is a wide spectrum of clinical disease, including mild fever, upper respiratory tract infections, aseptic meningitis, myocarditis, and encephalitis.

Enteroviruses also cause more specific syndromes, such as hand, foot, and mouth disease; herpangina; hemorrhagic conjunctivitis; and pleurodynia.

Management Strategy

The majority of enterovirus infections are mild and self-limited, peaking in summer and fall seasons. The viruses are transmitted by the orofecal route, and distribution is worldwide. Young children are most frequently affected and commonly present with fever, malaise, diarrhea, vomiting, and upper respiratory symptoms. The exanthem is typically a nonpruritic, morbilliform eruption, often with a petechial component.

Hand, foot, and mouth disease is typically caused by coxsackievirus A16. There is a prodrome of fever, malaise, and sore throat followed by painful red macules, which become vesicles, on the tongue, soft palate, uvula, and tonsillar pillars. Ovoid, opaque vesicles with a surrounding rim of erythema may be noted on the hands, feet, and buttocks. The disease is usually self-limited. Epidemics in Taiwan, caused by enterovirus 71, led to deaths due to pulmonary hemorrhage/edema, meningitis, encephalitis, myocarditis, and flaccid paralysis.

Herpangina may present with a similar prodrome. White-gray vesicles with a rim of erythema are later observed on the soft palate, uvula, and tonsillar pillars. Typically fewer than 20 lesions are noted.

Enteroviral infections may be diagnosed by rapid or traditional viral culture of the oropharynx or stool and occasionally of the blood, CSF, urine, or tissue. The specific serotype can usually be identified. Disadvantages to viral culture include low sensitivity and slow turnover. Serology is not routinely used but is commercially available. Because all enteroviruses share common genomic sequences, PCR detects almost all enterovirus serotypes and is particularly reliable in the CSF.

Treatment of most enteroviral infections, including hand, foot, and mouth disease and herpangina, consists of *hydration* and *pain control*. These infections are of particular concern in newborns and immunosuppressed patients who have been treated with *immunoglobulin* for severe life-threatening illness. *Pleconaril* is an antiviral drug that prevents viral attachment and fusion and has the potential to improve morbidity and mortality. Presently, its use is

limited to severe life-threatening infections, specifically meningitis and neonatal sepsis. Small interfering RNA (siRNA) shows promise as a future treatment option.

Specific Investigations

- Viral culture
- Enteroviral PCR

First-Line Therapies

• Antipyretics such as acetaminophen or ibuprofen	E
• Analgesics	E
• Hydration	E

Second-Line Therapies

• Pleconaril	B

Enteroviral encephalitis in children: clinical features, pathophysiology, and treatment advances

Jain S, Patel B, Bhatt GC. Pathog Glob Health 2014; 108: 216–22.

Specific antiviral therapy is currently not available for enteroviral infections, but pleconaril and immunoglobulin are used to treat enteroviral infections of the central nervous system (CNS). Of note, immunoglobulin therapy has not been properly validated in clinical

trials. Bovine lactoferrin, shRNA (small hairpin RNA), siRNA, rupintrivir, ribavirin, and 17-AAG have been tested in vivo and may become future therapeutic options.

A randomized, double-blind, placebo-controlled trial of pleconaril for the treatment of neonates with enterovirus sepsis

Abzug MJ, Michaels MG, Wald E, Jacobs RF, Romero JR, Sánchez PJ, et al. J Pediatric Infect Dis Soc 2016; 5: 53–62.

Those treated with pleconaril had greater survival and earlier negative cultures and PCR tests compared with the placebo group.

Viral warts

Rabia S. Rashid, and Imtiaz Ahmed

Warts are a common disease caused by infection with various strains of the human papillomavirus (HPV). They appear on different sites of the body and in various forms, including common, flat, filiform, periungual, plantar, mosaic, and genital warts. Children

most commonly present with common or periungual warts on hands and feet, whereas adults often present with common warts on the back of hands or filiform warts on the face and neck. Genital warts are discussed in another chapter.

Management Strategy

Most warts resolve spontaneously with time. However, patients and children's parents often ask for treatment because of pain, social stigma, or concern over infectivity. In some cases warts cause ridicule, distorted self-image, impaired dexterity, worry over loss of employment, or a health and safety issue. Immunosuppressed patients may have extensive and resistant warts.

Most patients will treat themselves with over-the-counter preparations containing *keratolytics* before presenting to the dermatologist. Salicylic acid has the best evidence base and is the most commonly used therapy. It can be applied in various concentrations, with or without occlusion, and is suitable for any cutaneous site except the face. However, it requires frequent application, and it may cause irritation of the surrounding skin. *Cryotherapy* with dimethyl ether and propane applicator, silver nitrate pencils, and occlusive "duct tape" are also available over the counter.

When a dermatologist sees patients with warts, the diagnosis and the possibility of *spontaneous resolution* and watchful waiting should be explained. The patient should be educated on how to apply topical preparations accurately. Keeping the warts well pared down with the use of a file or pumice stone after soaking is especially important for plantar warts. Young and healthy individuals with short duration of infection have the highest clearance rate. Cryotherapy with liquid nitrogen is one of the most common treatments used by the dermatologist. Liquid nitrogen is applied with a cryospray or a cotton bud. The wart should be frozen outward from the center to include a 2-mm rim of normal skin and the freeze maintained for 5 seconds. Cryotherapy is best repeated at 2- to 3-week intervals. Hyperkeratotic warts should be pared before cryotherapy and plantar warts treated by two freeze-thaw cycles. This treatment is painful and not always well tolerated by young children. The treated warts are sore and may blister. In pigmented skin, posttreatment hypopigmentation and hyperpigmentation can be a problem. Cryotherapy with liquid nitrogen can be combined with other topical preparations such as

salicylic acid. Cryotherapy with carbon dioxide snow or dimethyl ether applicators does not produce temperatures as low as liquid nitrogen and is less effective.

If cryotherapy is not successful then various other options are available, including *immunotherapy* with diphencyprone (DCP), squaric acid, and intralesional mumps or *Candida* antigen. *Intralesional bleomycin* may be injected into the wart or the solution applied to the wart and then repeatedly pricked through with a lancet. Laser ablation, hyperthermia, curettage and cautery, or even surgical excision of troublesome and resistant warts can be attempted, but the risk of scarring and recurrence of the warts in the scar can be a problem. The *pulsed dye laser* (PDL), thought to target the rich capillary network in warts, can be effective. *Photodynamic therapy* (PDT) is another option; however, pain during and after ALA (aminolevulinic acid)-PDT is well recognized. *Other treatments* used occasionally include 5-fluorouracil, zinc, levamisole, cimetidine, topical and oral retinoids, and imiquimod.

First-Line Therapies

• Salicylic acid preparations	A
• Silver nitrate	B
• Cryotherapy with dimethyl ether and propane	C

An assessment of methods of treating viral warts by comparative treatment trials based on a standard design

Bunney MH, Nolan MW, Williams DA. Br J Dermatol 1976; 94: 667–79.

This paper looked into 11 trials with over 1800 patients. In a randomized blind trial involving 389 patients, salicylic acid with lactic acid paint was as effective as cryotherapy with liquid nitrogen, with cure rates of 67% and 69%, respectively. The salicylic acid with lactic acid paint comprised 17% salicylic acid, 17% lactic acid, and 66% flexible collodion. In another study of 382 warts, 84% of patients were

cured after 12 weeks of salicylic acid with lactic acid paint application. A separate study showed a 44% clearance with salicylic acid and lactic acid paint versus 47% of patients applying 10% glutaraldehyde.

Topical treatments for cutaneous warts

Kwok CS, Gibbs S, Bennett C, Holland R, Abbott R. Cochrane Database Syst Rev 2013; 9: CD001781.

This updated review contained 26 new studies. According to 85 trials meeting the criteria for inclusion, the best evidenced therapy for cutaneous warts is for salicylic acid. Data pooled from six placebo-controlled trials showed a statistically significant result favoring the topical application of salicylic acid for warts at all sites (response rate [RR] 1.56, 95% confidence interval, 1.20–2.03). On the contrary, no benefit was found between cryotherapy and placebo in three studies.

Efficacy of 10% silver nitrate solution in the treatment of common warts: a placebo-controlled, randomized, clinical trial

Ebrahimi S, Dabiri N, Jamshidnejad E, Sarkari B. Int J Dermatol 2007; 46: 215–7.

A topical solution of 10% silver nitrate applied to the warts on alternate days for 3 weeks in 30 patients resulted in complete clearance in 63% of patients after 6 weeks in the treatment group versus no healing in the placebo group.

Cryosurgical treatment of warts: dimethyl ether and propane versus liquid nitrogen: case report and review of the literature

Nguyen NV, Burkhart CG. J Drugs Dermatol 2011; 10: 1174–6.

Other coolants are probably less effective than liquid nitrogen.

Second-Line Therapies

• Cryotherapy with liquid nitrogen	B
• Cryotherapy in combination with salicylic acid	B

Cryotherapy versus salicylic acid for the treatment of plantar

warts: a randomised controlled trial

Cockayne S, Hewitt C, Hicks K, Jayakody S, Kang'ombe AR, Stamuli E, et al. BMJ 2011; 342: d3271.

A study of 240 patients treated by health care professionals with liquid nitrogen, for up to four treatments, 2 to 3 weeks apart, was compared with patient self-treatment with 50% salicylic acid daily, for up to 8 weeks. Overall, 14% had complete clearance at 12 weeks, with no significant difference between the two groups.

A two-week interval is better than a three-week interval for reducing the recurrence rate of hand-foot viral warts after cryotherapy: a retrospective review of 560 hand-foot viral warts patients

Youn SH, Kwon IH, Park EJ, Kim KH, Kim KJ. Ann Dermatol 2011; 23: 53–60.

In a retrospective study with 560 patients, a 2-week interval was compared with a 3-week interval between cryotherapy with liquid nitrogen. For the 2- and 3-week groups, cure rates were 77% and 75%, respectively. Recurrence rates were 13% and 25%, and mean time to recurrence was 9.8 months and 6.9 months, respectively.

Two-week cryotherapy is optimal not only because of the rapid cure but also because of the lower recurrence rate.

Cryotherapy of common viral warts at intervals of 1, 2 and 3 weeks

Bourke JF, Berth-Jones J, Hutchinson PE. Br J Dermatol 1995; 132: 433–6.

This study carried out on 225 patients showed a 45% cure rate for warts treated with liquid nitrogen. The mean times to clearance of warts in each group were 5.5, 9.5, and 15 weeks in the weekly, 2- and 3-weekly groups, respectively. The mean numbers of treatments needed to achieve clearance were similar in each group (5.5, 4.75, and 5 treatments). The study showed that clearance of the warts was related to the number of treatments received, and it was independent of the interval between treatments.

Value of a second freeze–thaw cycle in cryotherapy of common warts

Berth-Jones J, Bourke J, Eglitis H, Harper C, Kirk P, Pavord S, et al. Br J Dermatol 1994; 131: 883–6.

In a randomized trial 300 patients received cryotherapy with either one or two freeze–thaw cycles at a 3-week interval. In addition, all subjects used keratolytic wart paints, and plantar warts were pared before freezing. At 3 months, the cure rate was 57% from the single freeze technique versus 62% from the double freeze technique. In plantar warts, the cure rate was 41% from single freezing and 65% for double freezing, whereas in the hand warts there was no additional benefit from the second freeze.

Liquid nitrogen and salicylic/lactic acid paint in the treatment of cutaneous warts in general practice

Steele K, Irwin WG. J R Coll Gen Pract 1988; 38: 256–8.

In this randomized study 207 patients with common hand warts and simple plantar warts were assigned to one of three treatment groups: cotton wool bud cryotherapy applied weekly, daily application of wart paint (lactic acid one part, salicylic acid one part, collodion four parts), or a combination of the two. Combination therapy cured 87% of common hand warts over a 6-week period and was significantly more effective than either agent used separately ($p < 0.05$). The results for simple plantar warts were disappointing, and no treatment regimen proved to be significantly better than any other.

Third-Line Therapies

Immunologic therapy

• Imiquimod	B
• Contact immunotherapy	
• Diphencyprone	B
• Squaric acid	D

• Echinacea	B

Immunologic Therapy

Topical treatment of warts and mollusca with imiquimod

Hengge UR, Goos M. Ann Intern Med 2000; 132: 95.

In this trial, 65 patients with warts and molluscum were treated with 5% topical imiquimod and achieved 56% clearance of recalcitrant warts after 9.5 weeks of treatments. The frequency of imiquimod treatment was not stated by the authors.

Topical 5% imiquimod long-term treatment of cutaneous warts resistant to standard therapy modalities

Grussendorf-Conen EI, Jacobs S, Rübber A, Dethlefsen U. Dermatology 2002; 205: 139–45.

In this study, 10 of 37 (27%) patients cleared with imiquimod self-applied twice daily with mean duration of 19 weeks.

Investigations of the efficacy of diphenylcyclopropenone immunotherapy for the treatment of warts

Suh DW, Lew BL, Sim WY. Int J Dermatol 2014; 53: e567–71.

Patients were sensitized with 0.1% diphenylcyclopropenone (DPCP), and 2 weeks after sensitization, DPCP was applied to warts weekly. High clearance rates of 141/170 patients (82.9%) were

achieved and 434/511 lesions (84.9%). Immunotherapy proved more effective in patients <20 years of age and for hand warts. The mean $\pm$ standard deviation number of applications was 9.02 ± 2.59 . Side effects occurred in 36 patients, with blistering at the sensitized site being the most common. No serious adverse events occurred.

Diphencyprone immunotherapy for viral warts in immunosuppressed patients

Audrain H, Siddiqui H, Buckley DA. Br J Dermatol 2013; 168: 1138–9.

Ten immunosuppressed patients and 28 immunocompetent patients with refractory warts were sensitized with 1% DCP, with a repeat application at 1 week. DCP was then applied to all warts at 2- to 4-week intervals. In the immunocompetent group, 27 patients (96%) cleared completely with a median of six treatments over 7 months. In the immunosuppressed group, six patients (60%) cleared completely with a median of 9.5 treatments over 9 months, and the remaining four also improved.

Does immunotherapy of viral warts provide beneficial effects when it is combined with conventional therapy?

Choi JW, Cho S, Lee JH. Ann Dermatol 2011; 23: 282–7.

This study assessed the efficacy DCP as an adjunctive to cryotherapy. Retrospective chart review of 124 patients with warts showed that DCP may be a successful adjuvant to cryotherapy in reducing the number of cryotherapy sessions.

Squaric acid immunotherapy for warts in children

Silverberg NB, Lim JK, Paller AS, Mancini AJ. J Am Acad Dermatol 2000; 42: 803–8.

In this retrospective study, 61 children had their warts treated with home application of 0.2% squaric acid, 3 to 7 nights per week, for at least 3 months, after initial sensitization with 2% squaric acid on the forearm. Complete clearance after 7 weeks of this treatment occurred in 58% of patients, partial clearance occurred in 18%, and no response in 24%.

Treatment of common and plane warts in children with topical viable bacillus Calmette-Guerin

Salem A, Nofal A, Hosny D. Pediatr Dermatol 2013; 30: 60–3.

Topical BCG paste (containing 3 mg of salicylic acid, dissolved in 3

mL of glycerin) was applied to all warts in 40 children, weekly for maximum of 12 weeks. A control group of 40 children were treated with saline once weekly for same duration. Complete response occurred in 65% of children with common warts and 45% of plane warts with no response in the control group. A statistically significant difference was found between the active and control groups.

Intralesional *Candida* antigen immunotherapy for the treatment of recalcitrant and multiple warts in children

Muñoz Garza FZ, Roé Crespo E, Torres Pradilla M, Aguilera Peiró P, Baltá Cruz S, Hernández Ruiz ME, et al. *Pediatr Dermatol* 2015; 32: 797–801.

In this retrospective review, 220 children with refractory warts received three intralesional injections of 0.2 mL of *Candida albicans* antigen, one per visit, at 3-week intervals. Results showed that 156 (70.9%) had a complete response, 37 (16.8%) had a partial response, and 27 (12.2%) had no response. An average of 2.7 injections were required.

Two-year experience of using the measles, mumps and rubella vaccine as intralesional immunotherapy for warts

Na CH, Choi H, Song SH, Kim MS, Shin BS. *Clin and Exp Dermatol* 2014; 39: 583–9.

A retrospective study of 136 patients with various types of warts were treated for a total of six times at 2-week intervals. Thirty-six patients (26.5%) experienced complete resolution with an average of five treatments; 51.5% experienced >50% reduction in size and number of warts. Common warts showed statistically higher treatment response than other types of warts.

Cimetidine therapy for recalcitrant warts in adults: is it any better than placebo?

Rogers CJ, Gibney MD, Siegfried EC, Harrison BR, Glaser DA. *J Am Acad Dermatol* 1999; 41: 123–7.

In this double-blind, placebo-controlled study, 70 patients with multiple viral warts were randomized to cimetidine 25 to 40 mg/kg daily or placebo for 3 months. Cimetidine was found to be no more effective than placebo.

Cimetidine therapy for recalcitrant warts in adults

Glass AT, Solomon BA. Arch Dermatol 1996; 132: 680–2.

In this prospective study, 20 patients received cimetidine 30 to 40 mg/kg/day. Complete resolution or a dramatic improvement was achieved in 84% of the 18 patients after 3 months.

Topical zinc oxide vs. salicylic acid-lactic acid combination in the treatment of warts

Khattar JA, Musharrafieh UM, Tamim H, Hamadeh GN. Int J Dermatol 2007; 46: 427–30.

In this double-blind trial, 44 patients were treated with either 20% zinc oxide ointment or 15% salicylic acid ointment + 15% lactic acid ointment combination, twice daily for 3 months. In the zinc oxide group, 50% patients were cured versus 42% with salicylic acid–lactic acid.

Topical zinc sulfate solution for treatment of viral warts

Sharqie KE, Khorhseed AA, Al-Nuaimy AA. Saudi Med J 2007; 28: 1418–21.

Topical zinc sulfate solution used three times daily for 4 weeks led to a higher cure rate than water placebo in a double-blind trial of 40 patients with plane warts and 50 patients with common warts. The cure rate appeared to be dependent on the concentration of zinc solution used and was better for plane than common warts. For plane warts, cure rates were 85.7% for 10% zinc sulfate (6/7 patients), 42.8% for 5% zinc sulfate (3/7 patients), and 10% for placebo 10% (1/10 patients). For common warts, cure rates were 11%, 5%, and 0%, respectively.

Treatment of viral warts by intralesional injection of zinc sulphate

Sharquie KA, Al-Nuaimy AA. Ann Saudi Med 2002; 22: 26–8.

One hundred patients with 623 warts were divided into two groups. In the treatment group, 53 patients had 173 warts treated with 2% zinc sulfate intralesionally, whereas 176 warts were left untreated as control. Within 6 weeks in the treatment group 98% of the warts cleared versus none in the control group.

Evaluation of oral zinc sulfate effect on recalcitrant multiple viral warts: a randomized placebo-controlled clinical trial

Yeghoobi R, Sadighha A, Baktash D. J Am Acad Dermatol 2009; 60:

706–8.

After 2 months of treatment with oral zinc sulfate (10 mg/kg to a maximum of 600 mg daily), 78% of patients cleared their warts (25/32) compared with 13% in the placebo group (3/23). The baseline serum zinc levels did not differ significantly between the two groups, but mean levels in both groups were low pretreatment.

Oral zinc sulfate for unresponsive cutaneous viral warts: too good to be true? A double-blind, randomized, placebo-controlled trial

López-García DR, Gómez-Flores M, Arc-Mendoza AY, de la Fuente-García A, Ocampo-Candiani J. Clin Exp Dermatol 2009; 34: e984–5.

This double-blind randomized controlled trial (RCT) showed no difference between oral zinc sulfate and placebo.

Successful treatment of verruca plantaris with a single sublesional injection of interferon- α 2a

Aksakal AA, Ozden MG, Atahan C, Onder M. Clin Exp Dermatol 2009; 34: 16–9.

In this placebo-controlled, single-blind study, 45 patients with a variety of hand or foot warts were treated with single-dose 4.5 MU IFN- α 2a (three study arms) versus 8 controls treated with normal saline. As local anesthesia, liquid nitrogen was sprayed onto the injection site of the IFN group for 3 to 4 seconds. At 12-month follow-up 19/24 patients (79.2%) with single verruca plantaris cleared completely, whereas only 2/8 patients (25%) had partial response in the control group.

Destructive Therapies

Cantharidin treatment for recalcitrant facial flat warts: a preliminary study

Kartal Durmazlar SP, Atacan D, Eskioglu F. J Dermatolog Treat 2009; 20: 114–9.

A study of 15 patients with plane facial warts who were treated with cantharidin 0.7% solution applied for 4 to 6 hours, washed off, and repeated every 3 weeks. All 15 patients achieved clearance within 16 weeks with one to four treatments.

Glycolic acid 15% plus salicylic acid 2%: a new therapeutic pearl for facial flat warts

Rodríguez-Cerdeira C, Sánchez-Blanco E. Clin Aesthet Dermatol 2011; 4: 62–4.

All 20 patients who applied a fine layer of glycolic acid 15% and salicylic acid 2% gel to their warts once daily clinically were cured within 8 weeks.

A double blind, randomized trial of local formic acid puncture technique in the treatment of common warts

Faghihi G, Vali A, Radan M, Eslamieh G, Tajammoli S. Skinmed 2010; 8: 70–1.

In this trial, 34 patients applied 85% formic acid in distilled water solution on their warts on one side of the body and distilled water as placebo on the other side of the body every other day using a needle puncture technique. Follow-up occurred every 2 weeks for 3 months. Complete clearance was achieved in 91% of patients who received formic acid versus 10% in the placebo group.

Monochloroacetic acid application is an effective alternative to cryotherapy for common and plantar warts in primary care: a randomized controlled trial

Bruggink SC, Gussekloo J, Egberts PF, Bavinck JN, de Waal MW, Assendelft WJ, et al. J Invest Dermatol 2015; 135: 1261–7.

Patients were randomly allocated to monochloroacetic acid (MCA) versus liquid nitrogen cryotherapy every 2 weeks for common warts ($n = 188$) and MCA versus cryotherapy combined with daily salicylic acid (SA) self-application for patients with plantar warts ($n = 227$). MCA was found to be an effective alternative to cryotherapy for both types of warts with cure rates at 13 weeks comparable in all treatment groups. In the common wart group, cure rates were 43% for MCA and 54% for cryotherapy, and in the plantar wart group, cure rates were 46% for MCA and 39% for cryotherapy combined with SA.

Comparative study of topical 80% trichloroacetic acid with 35% trichloroacetic acid in the treatment of the common wart

Pezeshkpoor F, Banihashemi M, Yazdanpanah MJ, Yousefzadeh H, Sharghi M, Hoseinzadeh H. J Drugs Dermatol 2012; 11: e66–9.

In this single-blind study, 62 patients were randomly assigned to weekly treatment with TCA in two different concentrations until

complete clearance for a maximum of 6 weeks. Fifty-five patients were included in the final analysis. With the higher concentration of TCA, 46.7% of patients cleared >75% warts versus 12% for the lower concentration.

Local hyperthermia at 44°C for the treatment of plantar warts: a randomized, patient-blinded, placebo-controlled trial

Huo W, Gao XH, Sun XP, Qi RQ, Hong Y, Mchepange UO, et al. *J Infect Dis* 2010; 201: 1169–72.

In this study, 54 patients had their warts treated with local hyperthermia of 44°C with an infrared-emitting source for 30 minutes a day for three consecutive days plus two additional days 2 weeks later. Within 3 months, 54% of patients in the treatment group were cured versus 12% in the control group.

Controlled localized heat therapy in cutaneous warts

Stern P, Levine N. *Arch Dermatol* 1992; 128: 945–8.

In this placebo-controlled, randomized trial, 13 patients had their 29 warts treated by a handheld radiofrequency heat generator device between one and four times for 30 to 60 seconds so that a temperature of 50°C was achieved in the warts. Complete clearance was achieved in 86% in the heat therapy group versus 41% in the control group.

Electrosurgery vs. 40% salicylic acid in the treatment of warts

Sudhakar Rao KM, Ankad BS, Naidu V, Sampaghavi VV, Unni MM, Aruna MS. *J Clin Diagn Res* 2012; 6: 81–4.

In this prospective randomized comparative study, 60 patients with viral warts received either electrosurgery or 40% salicylic acid (protocol or equipment not specified) and were followed up monthly for 6 months. Clearance rate with electrosurgery was 90% (27 out of 30 patients) versus 16.7% with salicylic acid (5 out of 30 patients).

Pulsed dye laser treatment for facial flat warts

Grilo W, Boixeda P, Ballester A, Miguel-Morrondo A, Truchuelo T, Jaén P. *Dermatol Ther* 2014; 27: 31–5.

In this prospective study, 32 patients were treated with pulsed dye laser (PDL) at 595-nm wavelength, a laser energy density of 9 or 14 J/cm² with a spot size of 7 or 5 mm, respectively, with air cooling and a pulse duration of 0.5 millisecond. Patients were treated in one to two sessions, 3 weeks apart, with one to three passes for each session.

A complete response was noted in 14 patients (44%) and an excellent response in 18 patients (56%). There were only four recurrences at 1-year follow-up.

Pulsed-dye laser for recalcitrant viral warts: a retrospective case series of 227 patients

Sparreboom EE, Luijck HG, Luiting-Welkenhuyzen HA, Willems PW, Groeneveld CP, Bovenschen HJ. *Br J Dermatol* 2014; 171: 1270–3.

A retrospective study of 227 consecutive patients with recalcitrant warts (those that failed all available topical therapy and repetitive cryotherapy). Overall efficacy for PDL treatment was 86%. This was achieved with generally more powerful laser settings than in the previous literature. Up to six treatments with fluences of 12.5 to 15.0 J/cm² and treatment intervals of 3 to 4 weeks were recommended to achieve maximal treatment success.

Photodynamic therapy with 5-aminolaevulinic acid or placebo for recalcitrant foot and hand warts: randomized double-blind trial

Stender IM, Na R, Fogh H, Gluud C, Wulf HC. *Lancet* 2000; 335: 963–6.

Forty-five adults with refractory warts received ALA-PDT or placebo PDT and showed cure rates of 64/114 (56% of warts) and 47/113 (42% of warts), respectively, which was statistically significant ($p < 0.05$). All warts were also treated with paring and topical salicylic acid (Verucid).

Is the step-up therapy of topical 5-aminolevulinic acid photodynamic therapy effective and safe for the patients with recalcitrant facial flat wart?

Quian G, Wang S, Deng D, Yang G. *Dermatolog Ther* 2014; 27: 83–8.

Step-up therapy of ALA-PDT was used on 30 patients in a maximum of three treatment sessions. Concentrations of ALA used were 5%, 10%, and 20%, and the treatment was increased at 2-weekly intervals if clearance was not achieved, to a maximum of three treatment sessions. The treatment response was good with 12 patients clearing completely after one session, 3 by two sessions, and 10 by the third session. Tolerance to ALA-PDT could improve with step-up therapy.

Successful treatment of recalcitrant warts in pediatric patients

with carbon dioxide laser

Serour F, Somekh E. Eur J Pediatr Surg 2003; 13: 219–23.

In this case series, 40 children with 54 warts were treated with CO₂ laser ablation under local anesthesia. Healing time was 4 to 5 weeks, and there was no recurrence at 12 months. Hypopigmentation was noticed in 11 cases.

Combination of carbon dioxide laser therapy and artificial dermis application in plantar warts: human papilloma virus DNA analysis after treatment

Mitsuishi T, Sasagawa T, Kato T, Iida K, Ueno T, Ikeda M, et al. Dermatol Surg 2010; 36: 1401–5.

In 31 patients, CO₂ laser was used for ablation of 35 warts, and the defects were covered with artificial dermis. Follow-up periods ranged from 3 to 12 months. Complete clearance was achieved in 31/35 warts after one treatment. After complete remission, HPV DNA was not detected in the upper epidermis of the postoperative site.

Long-pulsed Nd:YAG laser treatment of warts: report on a series of 369 cases

Han TY, Lee JH, Lee CK, Ahn JY, Seo SJ, Hong CK. J Korean Med Sci 2009; 24: 889–93.

A 96% clearance rate of recalcitrant common, palmoplantar, and periungual warts was achieved in 369 patients treated with Nd:YAG laser over the course of a year.

Pulsed dye laser versus Nd:YAG in the treatment of plantar warts: a comparative study

El-Mohamady Ael-S, Mearag I, El-Khalawany M, Elshahed A, Shokeir H, Mahmoud A. Lasers Med Sci 2014; 29: 1111–6.

Forty-six subjects with multiple plantar warts were included in the study. In each patient, half the lesions were treated with Nd:YAG laser and half with PDL fortnightly for a maximum of six sessions. There was no significant difference between cure rates for PDL (73.9%) and Nd:YAG (78.3%), but Nd:YAG was more painful and associated with more complications.

Er:YAG laser followed by topical podophyllotoxin for hard to treat palmoplantar warts

Wollina U. J Cosmet Laser Ther 2003; 5: 35–7.

Complete resolution of warts was observed in 31/35 patients after treatment with Er:YAG laser, followed with topical podophyllotoxin for 3 days on, 4 days off, for up to six cycles.

Virucidal Treatments

Treatment of plantar warts in children

Vickers CF. BMJ 1961; 2: 743–5.

A study of 646 children with plantar warts showed that 3% formalin foot soaks to pared plantar warts for 15 to 20 minutes each night for 6 to 8 weeks cured 80% of the warts.

The U.S. National Toxicology Program (on June 10, 2011) described formaldehyde as “known to be a human carcinogen.”

An assessment of methods of treating viral warts by comparative treatment trials based on a standard design

Bunney MH, Nolan MW, Williams DA. Br J Dermatol 1976; 94: 667–79.

In a study of 81 patients with mosaic plantar warts, buffered 10% glutaraldehyde solution was compared with salicylic acid (SA) paint. There was no significant difference between the efficacies for SA paint (44% cure) and glutaraldehyde (47% cure) at 12 weeks.

Topical treatment of resistant warts with glutaraldehyde

Hirose R, Hiro M, Shakuwa T, Udano M, Yamada M, Koide T, et al. J Dermatol 1994; 21: 248–53.

A cure rate of 72% was achieved in 25 patients treated topically with 20% glutaraldehyde solution. The treatment did not cause pain or permanent pigmented change.

Glutaraldehyde is suitable for home treatment, as there is no need for special instruments or special technique, and the cure rates are almost equal to those with cryotherapy.

Cutaneous necrosis secondary to topical treatment of wart with 20 p. 100 glutaraldehyde solution

Prigent F, Iborra C, Meslay C. Ann Dermatol Venereol 1996; 123: 644–6.

Case reports like this led to the withdrawal of a glutaraldehyde product

from the market in France in December 1995.

Antiproliferative Agents

Wart treatment with anthralin

Flindt-Hansen H, Tikjob G, Brandrup F. Acta Derm Venereol 1984; 64: 177–9.

An RCT of dithranol 2% cream versus Verucid (11% SA, 4% lactic acid with copper) showed a higher cure rate for dithranol: 56% (15/27) versus 26% (8/31).

Treatment of plantar warts with elastoplast and podophyllin

Duthie DA, McCallum DI. BMJ 1951; 2: 216–8.

Forty patients with plantar warts were treated with podophyllin 25% in liquid paraffin under prolonged adhesive plaster occlusion, repeated at intervals of 1 to 2 weeks, and reported a clearance rate of 72.5% at 3 months.

A controlled trial on the use of topical 5-fluorouracil on viral warts

Hursthouse MW. Br J Dermatol 1975; 92: 93–5.

In this double-blind trial of 60 patients, 5-fluorouracil 5% cream was applied daily to hand or foot warts on one side of the body, whereas a placebo cream was applied on the other side of the body for 4 weeks. In the active group, 60% of patients cleared versus 17% in the placebo group.

Topical 5% 5-fluorouracil cream in the treatment of plantar warts: a prospective randomized and controlled clinical study

Salk RS, Grogan KA, Chang TJ. J Drugs Dermatol 2006; 5: 418–24.

In this study, 40 patients were treated either with 5-fluorouracil 5% with tape occlusion or tape occlusion alone with regular debridement for 12 weeks. In the active group 19/20 patients achieved complete cure versus 2 of 20 in the tape occlusion group.

Treatment of common warts with an intralesional mixture of 5-fluorouracil, lidocaine, and epinephrine: a prospective placebo-controlled, double-blind randomized trial

Yazdanafar A, Farshchian M, Fereydoonnejad M. Dermatol Surg 2008;

34: 656–9.

Forty patients were included in the study. A pair of warts on each subject was randomized to receive weekly intralesional 5-fluorouracil 4% (in combination with 2% lidocaine and 0.0125 mg/mL of epinephrine) or normal saline placebo. Sixty-five percent of warts cleared up with four injections compared with 35% in the placebo group.

Efficacy of intralesional bleomycin in palmo-plantar and periungual warts

Soni P, Khandelwal K, Aara N, Ghiya BC, Mehta RD, Bumb RA. *J Cutan Aesthet Surg* 2011; 4: 188–91.

Twenty-five patients were allocated to 0.1% intralesional bleomycin (1-mg/mL solution) or normal saline placebo fortnightly for maximum of two injections; 96% (82/85) of warts treated with bleomycin cleared, whereas only 11% of warts (8/72) treated with placebo showed clearance at 3 months. Moderate pain was observed in both groups, and no patients experienced systemic toxicity.

Intralesional bleomycin in the treatment of cutaneous warts: a randomized clinical trial comparing it with cryotherapy

Dhar SB, Rashid MM, Islam A, Bhuiyan M. *Indian J Dermatol Venereol Leprol* 2009; 75: 262–7.

Eighty participants were randomized to cryotherapy (one to four sessions) versus 0.1% intralesional bleomycin injection. Treatments were 3-weekly, using one body side for each treatment and a maximum of four treatments. The clearance rates in context of number of patients and number of warts were 94.9% and 97% for bleomycin and 76.5% and 82% for cryotherapy respectively ($p < 0.05$ by χ^2 analysis and $RR = 7.67$).

Recalcitrant warts and topical cidofovir: predictive factors of good response

Padilla España L, Del Boz J, Fernández-Morano T, Escudero-Santos I, Arenas-Villafranca J, de Troya M. *J Eur Acad Dermatol Venereol* 2016; 30: 1218–20.

A retrospective study of 126 immunocompetent patients treated with 3% or 1% cidofovir cream, with or without occlusion and once or twice a day, showed complete response in 67 (53.2%) and partial response in 35 (27.8%). Median duration of treatment was 12 weeks

and median follow-up 7 months. Based on their results, the authors recommended using cidofovir 3% cream initially twice daily with occlusion for a period of 12 weeks.

Intralesional cidofovir for the treatment of multiple and recalcitrant cutaneous viral warts

Broganelli P, Chiaretta A, Fragnelli B, Bernengo MG. *Dermatol Ther* 2012; 25: 468–71.

In an open study, 288 patients were treated with monthly intralesional injections of cidofovir (15 mg/mL). Resolution of warts occurred in 98% of patients, with an average of 3.2 injections required.

The efficacy of duct tape vs. cryotherapy in the treatment of verruca vulgaris (the common wart)

Focht DR, Spicer C, Fairchok MP. *Arch Pediatr Adolesc Med* 2002; 156: 971–4.

In this randomized study, 61 children and young adults received treatment with either cryotherapy with a 10-second freeze for a maximum of six treatments every 2 to 3 weeks or duct tape occlusion applied for 6.5 days every 7 days followed by debridement of the wart upon removal of tape for a maximum of 2 months. Complete resolution was achieved in 22/30 patients (71%) in the duct tape arm versus 15/31 (46%) in the cryotherapy group.

Efficacy of duct tape vs. placebo in the treatment of verruca vulgaris (warts) in primary school children

de Haen M, Spigt MG, van Uden CJT, van Neer P, Feron FJM, Knottnerus A. *Arch Paediatr Adolesc Med* 2006; 160: 1121–5.

No significant effect of duct tape occlusion.

Duct tape for the treatment of common warts in adults: a double blind randomized controlled trial

Wenner R, Askari SK, Cham PMH, Kedrowski DA, Liu A, Warshaw EM. *Arch Dermatol* 2007; 143: 309–13.

No difference between duct tape and moleskin occlusion.

Plantar warts treated with topical adapalene

Gupta R. *Indian J Dermatol* 2011; 56: 513–4.

All 118 warts cleared within 8 weeks in 10 patients treated with topical 0.1% adapalene gel after paring of warts. This was followed by

occlusive dressing with a polythene sheet for 1 week and continued until the clearance of all the warts.

Treatment of extensive and recalcitrant viral warts with acitretin

Choi YL, Lee KJ, Kim WS, Lee DY, Lee JH, Lee ES, et al. *Int J Dermatol* 2006; 45: 480–2.

In one case report, oral acitretin 1 mg/kg/day achieved almost complete clearance of recalcitrant warts on the hands after 2 months, but relapse occurred after cessation of therapy at 1 month, which promptly improved with resumption of acitretin.

A double-blind, randomized, placebo-controlled trial of oral isotretinoin in the treatment of recalcitrant facial flat warts

Olguin-Garcia MG, Jurado-Santa Cruz F, Peralta-Pedrero ML, Morales-Sánchez MA. *J Dermatol Treat* 2015; 26: 78–82.

Isotretinoin 30 mg/day or placebo was administered to 16 and 15 patients, respectively, for 12 weeks. All patients in the active treatment group showed complete resolution of warts versus no improvement in the placebo group ($p = 0.0001$). The most frequent adverse event was cheilitis. The patients did not undergo follow-up to assess for recurrence after the study ended.

Treatment of plane warts with a low-dose oral isotretinoin

Al-Hammy HR, Salman HA, Abdulsattar NA. *ISRN Dermatol* 2012; 2012:163929.

An open study of 26 child and adult patients with facial plane flat warts reported 73% clearance after 2 months of treatment with isotretinoin 0.5 mg/kg/day.

Complementary and Alternative Therapies

Effects of hypnotic, placebo, and salicylic acid treatments on wart regression

Spanos NP, Williams V, Gwynn MI. *Psychosom Med* 1990; 52: 109–14.

A randomized study comparing hypnosis with salicylic acid, control (no treatment), and placebo (base carrier from SA) showed a greater effect with hypnosis at 6-week follow-up, but the numbers were small (only 10 patients per group).

The successful treatment of flat warts with auricular acupuncture

Ning S, Li F, Qian L, Xu D, Huang Y, Xiao M, et al. *Int J Dermatol* 2012; 51: 211–5.

This single-blind, randomized study compared weekly auricular acupuncture with tretinoin 0.1% ointment nightly for 10 weeks. Overall, 53% (16/30) of patients treated with acupuncture cleared, compared with 3% (1 of 30) in the tretinoin group.

Oral supplementation with a nutraceutical containing echinacea, methionine and antioxidant/immunostimulating compounds in patients with cutaneous viral warts

Cassano N, Ferrari A, Fai D, Pettinato M, Pellé S, Del Brocco L, et al. *G Ital Dermatol Venereol* 2011; 146: 191–5.

The aim of this open-label study was to determine the effects of nutraceutical oral supplementation containing methionine, echinacea, zinc, and probiotics on the response of cutaneous warts to conventional standard therapy with salicylic and lactic acids or cryotherapy with liquid nitrogen. All 172 eligible patients were allocated to conventional standard therapy alone or combined conventional standard therapy with nutraceutical oral supplementation for 4 months. Complete remission was achieved in 55% of patients in the conventional standard therapy group versus 86% in the conventional standard therapy and oral supplementation group at 6 months' follow-up.

Vitiligo

John Harris, and Mehdi Rashighi

Vitiligo is a common autoimmune disease of the skin resulting from the destruction of epidermal melanocytes by cytotoxic CD8⁺ T cells. It presents with multiple white macules and patches, which can significantly affect patients' self-esteem and quality of life.

Vitiligo is estimated to affect about 1% to 2% of the population, regardless of gender and ethnicity (more than 3 million individuals in the United States). Existing treatments are nontargeted, time

consuming, and offer moderate efficacy. With the exception of *monobenzonone cream* (monobenzyl ether of hydroquinone), which is used to permanently depigment unaffected skin in patients with widespread vitiligo, there are currently no Food and Drug Administration (FDA)–approved medical treatments, and so management is primarily through the use of off-label therapies.

Management Strategy

The mainstay of treatment in vitiligo is *topical immunosuppressives* and *phototherapy*. Multiple factors, including disease extent, activity, and distribution, should be considered when developing a management strategy in each patient. These treatments may be less effective in patients with the segmental variant of vitiligo, which is characterized by rapid progression of depigmentation in a unilateral distribution, which then stabilizes and remains confined to this focal area.

Vitiligo is not a life-threatening condition; patients may therefore decline treatment. However, early and aggressive treatment is associated with better outcomes, which should be addressed with each patient. Regardless, education about the disease and psychological support should be offered to all patients. For treatment purposes, vitiligo patients are generally classified into two groups: patients with limited body surface area (BSA) involvement and patients with more widespread disease.

Segmental Vitiligo and Limited Vitiligo

First-line treatment in patients with limited body involvement, including segmental vitiligo, is treatment with *potent topical steroids* (clobetasol propionate 0.05%) and/or *calcineurin inhibitors* (tacrolimus 0.3%–0.1% or pimecrolimus 1%). Weaker steroids have not demonstrated efficacy in clinical trials, and thus potent steroids are preferred. Steroids are slightly more effective than calcineurin inhibitors in head-to-head studies; however, the potential side effects limit prolonged use, especially in areas such as the face, genitals, axillae and breasts. One common strategy is to use both steroids and topical calcineurin inhibitors in an alternating schedule. This can be achieved by application of steroids twice daily for 1 week, followed by calcineurin inhibitors twice daily for the next week, and continued in this way through an alternating weekly schedule. For sensitive

areas like the face, genitals, axillae, and breasts, use of calcineurin inhibitors without steroids is preferred.

Targeted *phototherapy devices* (excimer laser or monochromatic lamp), which deliver light in the UVB range (peak at 308 nm), can be considered a second-line option in patients who do not respond to topical treatments. Sessions are typically administered two or three times per week and continued for at least 3 months before deciding whether the patient is responsive to the treatment or not.

Surgical procedures can be considered in a minority of carefully selected patients with highly stable disease (at least 6 months without worsening of the existing lesions or development of new lesions) and have the best outcome in patients with the segmental variant. The main concept of this treatment is to transfer healthy melanocytes from nonlesional skin to the affected area within the same patient (autologous transplant). There are multiple different techniques to achieve this, including punch grafting, epidermal blister grafting, and cellular grafts, each with advantages and disadvantages. Epidermal cellular suspension transplant, however, is usually considered to provide the best outcome. Regardless of the technique being used, surgical procedures are contraindicated in patients with unstable disease or evidence of the Koebner phenomenon.

Widespread Disease (>3% BSA)

Phototherapy with *narrowband UVB* (NB-UVB) is considered the first-line treatment in patients with widespread disease and has largely replaced older phototherapy protocols. NB-UVB has been shown to be at least as effective as PUVA therapy with better color match, less risk of burning, and lower risk of skin cancer. Treatment should be delivered two or three sessions per week for at least 3 months and then continued for several additional months in patients who respond.

The decision to deliver two or three phototherapy sessions per week is usually based on patient compliance and personal preference. A three-session-per-week schedule induces a more rapid response; however, there is probably no significant difference between the two schedules in terms of the extent of repigmentation achieved after a prolonged period. NB-UVB therapy can be combined with topical steroids or calcineurin inhibitors to improve the treatment efficacy, especially in limited areas that might be cosmetically more important

to patients.

Systemic corticosteroids may be indicated to arrest disease activity in patients with highly progressive disease, before other therapies have time to demonstrate efficacy. This is usually delivered as pulse therapy (4 mg dexamethasone on Saturday and Sunday or alternate-day doses of 20 mg prednisone, e.g.) to reduce the risk of side effects.

Surgical procedures may be considered to treat selected areas with high cosmetic impact that do not respond to medical treatment. However, this should be reserved for stable lesions, particularly in those with segmental vitiligo, and only in patients with no evidence of koebnerization.

Maintenance Therapy

Relapse of disease is common after discontinuation of treatment. Tacrolimus 0.1% applied twice weekly may prevent relapse in patients and thus be a reasonable approach to maintenance therapy.

Emerging Treatments

Afamelanotide is a potent synthetic analog of α -melanocyte stimulating hormone (α -MSH), a naturally occurring neuropeptide that stimulates melanogenesis. Recently a small trial reported that a combination of afamelanotide with NB-UVB therapy may promote faster and more extensive repigmentation compared with phototherapy alone.

Janus kinase (JAK) inhibitors comprise a new class of drugs that selectively inhibit enzymes involved in signal transduction of several cytokines, including IFN- γ . Recently two patients with widespread vitiligo were reported to demonstrate significant repigmentation after being treated with two different oral JAK inhibitors, tofacitinib and ruxolitinib. Further studies are needed to determine whether this class of drugs is a safe and effective option in vitiligo treatment.

Pseudocatalase is a cream that is proposed to work as a topical oxygen radical scavenger in the skin. Consistent with a proposed role for elevated levels of melanocyte stress in vitiligo pathogenesis, studies have shown that there is an increased level of hydrogen peroxide (H_2O_2) in lesional skin of vitiligo patients. A small number of studies from a single investigator have reported that pseudocatalase may enhance repigmentation when combined with NB-UVB

phototherapy; however, others have been unable to reproduce these results, and larger independent studies are needed to confirm these observations.

Specific Investigation

- Screening for associated autoimmune diseases

Vitiligo is a clinical diagnosis, and a skin biopsy is rarely necessary. Patients with vitiligo generally have a higher incidence of other autoimmune diseases, including thyroiditis, type 1 diabetes, lupus, alopecia areata, Addison disease, and pernicious anemia. However, the majority of patients do not have any accompanying autoimmune disease, and directed medical history and physical examination are sufficient to identify high-risk individuals who require further evaluation.

Low yield of routine screening for thyroid dysfunction in asymptomatic patients with vitiligo

Kroon MW, Joore IC, Wind BS, Leloup MA, Wolkerstorfer A, Luiten RM, et al. Br J Dermatol 2012; 166: 532–8.

Thyroid function tests and anti-TPO antibody titers were assessed in 434 patients with nonsegmental vitiligo. The overall prevalence of thyroid dysfunction was higher than reported in the general population. However, most patients had symptoms indicative of thyroid dysfunction and had been already diagnosed by their general practitioners. Moreover, in the majority of these patients thyroid involvement preceded the onset of vitiligo. Thyroid disease was found mostly among older women and in subjects with a positive family history of thyroid disease. Thus a thorough review of systems for signs of thyroid disease is sufficient, and routine screening is not necessary.

First-Line Therapies

Segmental vitiligo or limited vitiligo

Effectiveness of 0.1% topical tacrolimus in adult and children patients with vitiligo

Udompataikul M, Boonsupthip P, Siri wattanagate R. J Dermatol 2011; 38: 536–40.

Forty-two patients (22 adults and 20 children) were enrolled. Tacrolimus 0.1% ointment was given twice daily for 6 months. The response rate was 76%. Children had approximately nine times better response than adults. Better response was found in patients with disease duration of 5 years or less.

A double-blind randomized trial of 0.1% tacrolimus vs. 0.05% clobetasol for the treatment of childhood vitiligo

Lepe V, Moncada B, Castanedo-Cazares JP, Torres-Alvarez MB, Ortiz CA, Torres-Rubalcava AB. Arch Dermatol 2003; 139: 581–5.

Twenty patients with vitiligo were treated for 2 months: 90% experienced some repigmentation. Repigmentation was 49.3% for clobetasol and 41.3% for tacrolimus. Tacrolimus is almost as effective as clobetasol and is better for sensitive areas (eyelids) because it does not cause skin atrophy.

Randomized double-blind trial of treatment of vitiligo: efficacy of psoralen-UV-A therapy vs. narrowband-UV-B therapy

Yones SS, Palmer RA, Garibaldinos TM, Hawk JL. Arch Dermatol 2007; 143: 643–6.

Fifty-six patients with nonsegmental vitiligo were enrolled into this randomized, double-blind, comparative trial. At the end of therapy, 64% of patients in the NB-UVB group showed greater than 50% improvement in BSA affected compared with 36% in the PUVA group. The color match of the repigmented skin was excellent in all patients in the NB-UVB group but in only 44% of those in the PUVA group ($p < 0.001$). In patients who completed 48 sessions, the improvement in BSA affected by vitiligo was greater with NB-UVB therapy than with PUVA therapy ($p = 0.007$). Twelve months after the cessation of therapy, the superiority of NB-UVB tended to be

maintained.

Treatment of vitiligo with narrowband-UVB (TL01) combined with tacrolimus ointment (0.1%) vs. placebo ointment, a randomized right/left double-blind comparative study

Nordal EJ, Guleng GE, Rönnevig JR. J Eur Acad Dermatol Venereol 2011; 25: 1440–3.

Whole-body NB-UVB was given twice or thrice weekly for at least 3 months. Forty patients were studied. Twenty-seven patients had a better effect on the tacrolimus side. Combination of NB-UVB and tacrolimus ointment (0.1%) was more effective than UV treatment alone.

The efficacy of pimecrolimus 1% cream plus narrow-band ultraviolet B in the treatment of vitiligo: a double-blind, placebo-controlled clinical trial

Esfandiarpour I, Ekhlasi A, Farajzadeh S, Shamsadini S. J Dermatol Treat 2008; 16: 1–5.

This study involved 68 patients. A combination of NB-UVB with pimecrolimus induced better pigmentation of facial lesions than did NB-UVB alone (64.3% vs. 25.1%).

Combining UV phototherapies with topical immunosuppressants carries a theoretical risk of enhancing carcinogenesis.

Maintenance therapy of adult vitiligo with 0.1% tacrolimus ointment: a randomized, double blind, placebo-controlled study

Cavalié M, Ezzedine K, Fontas E, Montaudie H, Castela E, Bahadoran P, et al. J Invest Dermatol 2015; 135: 970–4.

Thirty-five vitiligo patients with 71 therapeutically repigmented lesions were enrolled in a controlled trial. Patients were randomly assigned to receive placebo or treatment. Twice-weekly application of 0.1% tacrolimus ointment was found to be effective in preventing relapse in previously successfully repigmented lesions.

Second-Line Therapies

Segmental vitiligo or limited vitiligo

• Targeted phototherapy devices (excimer laser or monochromatic lamp)

A

Widespread vitiligo (>3% BSA)

• Systemic corticosteroids (oral minipulse therapy)

B

Vitiligo treatment with monochromatic excimer light (MEL) and tacrolimus: results of an open randomized controlled study

Nisticó S, Chiricozzi A, Saraceno R, Schipani C, Chimenti S.
Photomed Laser Surg 2012; 30: 26–30.

Fifty-three patients with vitiligo were enrolled. Combination treatment of 0.1% tacrolimus ointment (once daily) plus 308-nm MEL (twice per week) and 308-nm MEL monotherapy for 12 weeks are both effective and safe for the treatment of vitiligo. The combination of topical immunomodulators could enhance the clinical response in vitiligo, especially in resistant sites.

The efficacy of 308-nm excimer laser/light (EL) and topical agent combination therapy versus EL monotherapy for vitiligo: a systematic review and meta-analysis of randomized controlled trials (RCTs)

Bae JM, Hong BY, Lee JH, Lee JH, Kim GM. J Am Acad Dermatol 2016; 74: 907–15.

Eight randomized controlled trials comprising a total of 425 patches/patients that assessed the efficacy of EL alone or in combination with topical treatments were analyzed. Topical calcineurin inhibitors in conjunction with EL were found to be more effective in treating vitiligo compared with EL alone.

Efficacy and safety of 308-nm monochromatic excimer lamp versus other phototherapy devices for vitiligo: a systematic review with meta-analysis

Lopes C, Trevisani VF, Melnik T. Am J Clin Dermatol 2016; 17: 23–32.

Six randomized controlled trials comprising a total of 411 patients/764 lesions that compared the efficacy of monochromatic excimer lamp versus excimer laser and NB-UVB were analyzed. These three modalities were all found to be safe and effective in treating vitiligo, and no significant differences were found among them.

Combination therapy with 308-nm excimer laser, topical tacrolimus, and short-term systemic corticosteroids for segmental vitiligo: a retrospective study of 159 patients

Bae JM, Yoo HJ, Kim H, Lee JH, Kim GM. *J Am Acad Dermatol* 2015; 73: 76–82.

A retrospective interventional case-series study was performed on 159 patients with segmental vitiligo to assess the effectiveness of combination therapy with 308-nm excimer laser, topical tacrolimus, and short-term systemic corticosteroids. The combination therapy was found to be effective, and prolonged disease duration, poliosis, and plurisegmental subtype were shown to be independent prognostic factors of poor response to the treatment.

Randomized controlled trial comparing the effectiveness of 308-nm excimer laser alone or in combination with topical hydrocortisone 17-butyrate cream in the treatment of vitiligo of the face and neck

Sassi F, Cazzaniga S, Tessari G, Chatenoud L, Reseghetti A, Marchesi L, et al. *Br J Dermatol* 2008; 159: 1186–91.

Eighty-four patients were treated with 308-nm excimer laser twice weekly alone or in combination with topical hydrocortisone 17-butyrate cream twice daily for 3 weeks. A total of 16.6% patients in the excimer monotherapy group and 42.8% in the combination group showed 75% or more reduction of vitiligo lesions at 12 weeks.

Randomized, parallel group trial comparing home-based phototherapy with institution-based 308 excimer lamp for the treatment of focal vitiligo vulgaris

Tien Guan ST, Theng C, Chang A. *J Am Acad Dermatol* 2015; 72: 733–5.

Forty-four patients with stable focal vitiligo were randomized to receive either three-times-a-week, home-based phototherapy or twice-a-week excimer laser in the clinic. Patients who received the home-based phototherapy were found to have a better response, primarily due to a higher compliance to the treatment.

Inpatient comparison of 308-nm monochromatic excimer light and localized narrow-band UVB phototherapy in the treatment of vitiligo: a randomized controlled trial

Verhaeghe E, Lodewick E, van Geel N, Lambert J. *Dermatology* 2011;

223: 343–8.

Eleven patients participated in this prospective, inpatient, placebo-controlled, randomized trial. In each patient, three lesions were selected and treated with 308-nm excimer light, localized 311-nm NB-UVB, or placebo during 24 sessions. NB-UVB efficacy was found to be superior to excimer laser in inducing repigmentation.

A randomized comparative study of oral corticosteroid minipulse and low-dose oral methotrexate in the treatment of unstable vitiligo

Singh H, Kumaran MS, Bains A, Parsad D. *Dermatology* 2015; 231: 286–90.

Fifty-two patients with unstable vitiligo were enrolled in a prospective open-label noninferiority study and randomly assigned to oral methotrexate (10 mg weekly) or oral minipulse dexamethasone (2.5 mg on two consecutive days in a week) for 24 weeks. Both drugs were found to be equally effective in controlling the disease activity.

Third-Line Therapies

Segmental vitiligo or limited vitiligo

• Surgical treatment (autologous melanocyte transplant)	A
---	----------

Widespread vitiligo (>3% BSA)

• Surgical treatment (autologous melanocyte transplant)	A
• Monobenzyl ether of hydroquinone	C

A systematic review of autologous transplantation methods in vitiligo

Njoo MD, Westerhof W, Bos JD, Bossuyt PM. *Arch Dermatol* 1998; 134: 1543–9.

Sixty-three studies were analyzed: 16 on minigrafting, 13 on split-thickness grafting, 15 on grafting of epidermal blisters, 17 on grafting of cultured melanocytes, and 2 on grafting of noncultured epidermal

suspension. The highest success rates were achieved with split-skin grafting and epidermal blister grafting.

Treatment of vitiligo by transplantation of cultured pure melanocyte suspension: analysis of 120 cases

Chen YF, Yang PY, Hu DN, Kuo FS, Hung CS, Hung CM. J Am Acad Dermatol 2004; 51: 68–74.

A total of 120 patients were treated with transplantation of autologous cultured pure melanocyte suspension after CO₂ laser abrasion. Overall, 90% to 100% coverage was achieved in 84% of patients with stable localized vitiligo and in 54% of patients with stable generalized vitiligo, but only 14% of patients with active generalized vitiligo achieved good repigmentation.

Repigmentation of vitiligo with punch grafting and narrow-band UV-B (311 nm) – a prospective study

Lahiri K, Malakar S, Sarma N, Banerjee U. Int J Dermatol 2006; 45: 649–55.

Punch grafts were used to treat 66 patients with stable refractory vitiligo in different regions, followed by NB-UVB. Successful pigmentation was achieved in 86.36% of cases.

Comparison of minipunch grafting versus split-skin grafting in chronic stable vitiligo

Khandpur S, Sharma VK, Manchanda Y. Dermatol Surg 2005; 31: 436–41.

Sixty-four patients with stable vitiligo were involved. Grafting was followed by PUVA sol. Split-skin grafting gave much better repigmentation and cosmetic matching than minipunch grafting (83.3% of patients vs. 44.1%).

Subjective and objective evaluation of noncultured epidermal cellular grafting for repigmenting vitiligo

van Geel N, Vander Haeghen Y, Vervaet C, Naeyaert JM, Ongenae K. Dermatology 2006; 213: 23–9.

Noncultured autologous melanocytes and keratinocytes were used to treat 40 patients with stable refractory vitiligo: 70% or more repigmentation was noted in 62% of patients.

Epidermal grafting in vitiligo: influence of age, site of lesion, and

type of disease on outcome

Gupta S, Kumar B. *J Am Acad Dermatol* 2003; 49: 99–104.

This was a retrospective, uncontrolled case series and literature review of suction blister epidermal grafting in patients with stable and recalcitrant vitiligo. The procedure outcome was found to be significantly better in segmental/focal vitiligo than in the generalized type and in individuals <20 years of age. However, unlike in medical therapies, localization of the vitiligo patch did not appear to influence the treatment outcome significantly.

The additive effect of excimer laser on noncultured melanocyte-keratinocyte transplantation for the treatment of vitiligo: a clinical trial in an Iranian population

Ebadi A, Rad MM, Nazari S, Fesharaki RJ, Ghalamkarpour F, Younespour S. *J Eur Acad Dermatol Venereol* 2015; 29: 745–51.

Thirty-nine patches from 10 patients with stable generalized vitiligo were enrolled in a nonrandomized comparative trial. Application of two to three times weekly excimer laser (308 nm) for 24 sessions, starting 2 weeks after transplant procedure, significantly increased the pigmentation rate in the treated areas.

Surgical interventions for vitiligo: an evidence-based review

Mulekar SV, Isedeh P. *Br J Dermatol* 2013; 169 (Suppl 3): 57–66.

A systematic literature review of studies reporting on vitiligo surgical therapies found that the split-thickness skin grafts had the highest repigmentation success rate compared with the other surgical methods, including punch/minigraft, blister roof grafting, cultured, and noncultured cellular transplantation. Overall, postoperative complications included milia, scarring, cobblestone appearance, or hyperpigmentation of treated areas.

A randomized comparison of excimer laser versus narrow-band ultraviolet B phototherapy after punch grafting in stable vitiligo patients

Linthorst Homan MW, Spuls PI, Nieuweboer-Krobotova L, de Korte J, Sprangers MA, Bos JD, et al. *J Eur Acad Dermatol Venereol* 2012; 26: 690–5.

Fourteen patients were treated with the punch-grafting technique on two symmetric vitiligo patches. Starting 1 week after the punch grafting, the vitiligo patches were treated twice weekly with either

308-nm excimer laser or NB-UVB. No difference was found in repigmentation rate between the two methods, but patients were significantly more satisfied with NB-UVB, primarily due to a more rapid response.

Comparison between autologous noncultured epidermal cell suspension and suction blister epidermal grafting in stable vitiligo: a randomized study

Budania A, Parsad D, Kanwar AJ, Dogra S. Br J Dermatol 2012; 167: 1295–1301.

Forty-one patients with 54 stable vitiligo lesions were randomized to receive either autologous noncultured epidermal cell suspension (NCES) or suction blister epidermal grafting (SBEG). The follow-up evaluation 16 weeks after surgery indicated that NCES was superior to SBEG in terms of the extent of repigmentation and improvement in the Dermatology Life Quality Index.

A randomized controlled study of the effects of different modalities of narrow-band ultraviolet B therapy on the outcome of cultured autologous melanocytes transplantation in treating vitiligo

Zhang DM, Hong WS, Fu LF, Wei XD, Xu AE. Dermatol Surg 2014; 40: 420–6.

Four hundred thirty-seven patients undergoing cultured autologous melanocyte transplantation were randomly assigned to receive NB-UVB therapy before and/or after the procedure. Combination of transplantation with NB-UVB therapy both before and after the procedure resulted in the best treatment response.

Comparison between autologous noncultured extracted hair follicle outer root sheath cell suspension and autologous noncultured epidermal cell suspension in the treatment of stable vitiligo: a randomized study

Singh C, Parsad D, Kanwar AJ, Dogra S, Kumar R. Br J Dermatol 2013; 169: 287–93.

Thirty patients with 47 stable vitiligo lesions were randomized to receive either autologous noncultured “epidermal cell suspension” or “extracted hair follicle outer root sheath cell suspension.” Both techniques were found to be safe and effective in inducing repigmentation with comparable efficacy.

Monobenzyl ether of hydroquinone

Moser D, Parrish J, Fitzpatrick T. Br J Dermatol 1977; 97: 669–79.

In eighteen patients treated with monobenzyl ether of hydroquinone therapy twice daily over a 1-year period, eight achieved complete depigmentation and three had marked depigmentation. The depigmentation was permanent. Side effects were erythema, pruritus, and contact dermatitis.

Emerging Treatments

Tofacitinib citrate for the treatment of vitiligo: a pathogenesis-directed therapy

Craiglow BG, King BA. JAMA Dermatol 2015; 151: 1110–2.

This is the first report of a vitiligo patient being successfully treated by an oral JAK inhibitor. The patient was initiated on oral tofacitinib, a JAK 1/3 inhibitor, 5 mg every other day for 3 weeks, which was later increased to 5 mg daily. Five months after starting the treatment the patient showed significant repigmentation on her forehead and hands.

Rapid skin repigmentation on oral ruxolitinib in a patient with coexistent vitiligo and alopecia areata (AA)

Harris JE, Rashighi M, Nguyen N, Jabbari A, Ulerio G, Clynes R, et al. J Am Acad Dermatol 2016; 74: 370–1.

A patient with coexistent vitiligo and AA was initiated on 20 mg twice daily of oral ruxolitinib, a JAK 1/2 inhibitor. Twelve weeks after starting the treatment, the patient noted some repigmentation on his face in addition to scalp hair regrowth. At week 20, the patient exhibited substantial repigmentation on his face and other areas. Twelve weeks after discontinuing ruxolitinib, although his hair regrowth was maintained, much of the regained pigment had regressed.

Afamelanotide and narrowband UV-B phototherapy for the treatment of vitiligo: a randomized multicenter trial

Lim HW, Grimes PE, Agbai O, Hamzavi I, Henderson M, Haddican M, et al. JAMA Dermatol 2015; 151: 42–50.

Fifty-five patients with generalized vitiligo were randomized to NB-UVB therapy or NB-UVB in combination with afamelanotide, an

analog of α -melanocyte-stimulating hormone. Monthly subcutaneous implantation of 16 mg of afamelanotide resulted in a significantly superior and faster repigmentation compared with NB-UVB monotherapy, especially in patients with darker skin type.

From basic research to the bedside: efficacy of topical treatment with pseudocatalase PC-KUS in 71 children with vitiligo

Schallreuter KU, Krüger C, Würfel BA, Panske A, Wood JM. Int J Dermatol 2008; 47: 743–53.

This was an uncontrolled retrospective study to assess the efficacy of topical NB-UVB-activated pseudocatalase. Seventy-one children with vitiligo were included. The majority of patients exhibited at least 75% repigmentation on their face, neck, and trunk, but the treatment was not effective on the hands or feet.

Vulvodynia

Yasaman Mansouri

Vulvodynia is defined as “vulvar pain of at least 3 months’ duration, without clear identifiable cause, which may have potential associated factors.” This new terminology was formed in 2015 by a consensus among international expert societies. Typical symptoms are burning, stinging, rawness, irritation, and associated dyspareunia. Vulvodynia can be further described as localized (e.g., vestibulodynia, clitorodynia) or generalized, provoked (elicited by contact), spontaneous, or mixed. Onset may be primary (present since the patient’s first episode of vaginal penetration) or secondary (after a period of pain-free activities). Localized provoked vulvodynia is the most common subtype. Vulvodynia is a common condition that is poorly understood. The pathogenesis is likely multifactorial and may involve genetic predisposition, hormonal factors, pelvic floor muscle dysfunction, inflammation, and immune factors. Other pain conditions such as interstitial cystitis, fibromyalgia, temporomandibular joint disorder, or irritable bowel syndrome may occur in the same patient.

Vulvodynia can be distressing to patients, and clinicians are often not familiar and comfortable in managing this disease.

Management Strategy

Vulvodynia is a diagnosis of exclusion. Thorough physical examination and appropriate laboratory testing should be performed to exclude other etiologies of pain, including infections, dermatoses, endometriosis, and neurologic conditions (e.g., herpes neuralgia,

spinal nerve compression). A complete evaluation should include detailed pain, medical, surgical, and sexual histories and psychological assessment.

Treatment is challenging, and despite its prevalence, most treatments for vulvodynia are not well studied and are largely based on expert opinion and uncontrolled studies. The therapeutic approach should be individualized and multidisciplinary, including dermatology, gynecology, physical therapy, and psychology. No single treatment is effective in all women, and many therapies are often tried before relief is achieved. Noninvasive treatments are often tried first, including topical lidocaine, pelvic floor physical therapy, antidepressants, and anticonvulsants. Combining treatments may be beneficial. Surgical interventions are reserved for women refractory to other modalities and are not considered first-line due to their invasive nature. However, high success rates have been reported with vestibulectomy, which can be considered in patients with localized disease.

Specific Investigations

- Visual and manual examination of the vulva, vagina, oral cavity, skin, scalp, and nails
- Assessment of pelvic floor musculature
- Palpation of inguinal lymph nodes
- Cotton swab testing of entire genital region, including vulval vestibule for point tenderness
- Tampon test
- Wet mount of vaginal secretions (*Trichomonas vaginalis*, bacterial vaginosis)
- pH assessment of vaginal secretions (bacterial vaginosis, atrophic vaginitis, inflammatory vaginitis)
- KOH microscopic examination (fungi, scabies)
- Microbiologic cultures (bacterial, yeast, viral)
- Papanicolaou smear (in select cases)
- Colposcopy of vulva (in select cases)
- Biopsy, if lesion present
- Patch testing (allergic contact dermatitis)
- Psychological evaluation

Current concepts in vulvodynia with a focus on pathogenesis and pain mechanisms

Thornton AM, Drummond C. *Australas J Dermatol* 2016; 57: 253–63.

This review article discusses the possible pathogenesis of vulvodynia and assessment of patients and proposes a therapeutic ladder.

Vulvodynia: assessment and treatment

Goldstein AT, Pukall CF, Brown C, Bergeron S, Stein A, Kellogg-Spadt S. *J Sex Med* 2016; 13: 572–90.

Comprehensive review of evaluation of vulvodynia patients with suggested treatment options.

2013 vulvodynia guideline update

Stockdale CK, Lawson HW. *J Low Genit Tract Dis* 2014; 18: 93–100.

This article reviews clinical diagnosis and therapeutic approaches.

Impact of a multidisciplinary vulvodynia program on sexual functioning and dyspareunia

Brotto LA, Yong P, Smith KB, Sadownik LA. *J Sex Med* 2015; 12: 238–47.

This study evaluated the efficacy of a multidisciplinary program in 132 patients. Treatments included educational seminars, psychological skills training, pelvic floor physiotherapy, and gynecologic management. Results showed significant reduction in dyspareunia and sex-related distress.

Women with provoked vestibulodynia experience clinically significant reductions in pain regardless of treatment: results from a 2-year follow-up study

Davis SN, Bergeron S, Binik YM, Lambert B. *J Sex Med* 2013; 10: 3080–7.

In this secondary analysis of a prospective study, 239 women completed a questionnaire at study initiation and after 2 years. Patients had received various therapies, although 41% did not undergo any treatment. At 2 years, there was significant improvement in pain, sexual function, and depression for the group as a whole. Women not receiving any treatment also improved significantly. The authors conclude that no single treatment is superior and that spontaneous resolution may occur.

First-Line Therapies

• Antidepressants (oral or topical amitriptyline, oral desipramine, oral milnacipran, etc.)	A
• Topical lidocaine	B
• Anticonvulsants (oral or topical gabapentin, oral pregabalin, oral lamotrigine)	C
• Pelvic floor physical therapy	C

Oral desipramine and topical lidocaine for vulvodynia: a randomized controlled trial

Foster DC, Kotok MB, Huang LS, Watts A, Oakes D, Howard FM, et al. *Obstet Gynecol* 2010; 116: 583–93.

This study consisted of four treatment arms. One hundred and thirty-three women with vulvodynia were randomly assigned to 12 weeks of oral desipramine, topical lidocaine, oral desipramine plus topical lidocaine, or placebo. There was no statistically significant benefit in pain reduction of the treatment arms compared with placebo. However, there was significant improvement in sexual functioning in the desipramine group. The authors discuss the importance of including a placebo arm in vulvodynia studies.

Self-management, amitriptyline, and amitriptyline plus triamcinolone in the management of vulvodynia

Brown CS, Wan J, Bachmann G, Rosen R. *J Womens Health* 2009; 18: 163–9.

In this open-label trial, 53 women were randomized to self-management, oral amitriptyline (10–20 mg/day), or topical triamcinolone plus oral amitriptyline. The treatment groups were not superior to self-management with regard to pain reduction. There were significant within-group differences in the amitriptyline group, but the authors state that these may not have been clinically meaningful.

Treatment of vulvodynia with tricyclic antidepressants: efficacy and associated factors

Reed BD, Caron AM, Gorenflo DW, Haefner HK. *J Low Genit Tract Dis* 2006; 10: 245–51.

A prospective cohort study of 209 women initially treated with a

tricyclic antidepressant (TCA). One hundred and eighty-three were given amitriptyline, 23 received desipramine, and 3 were treated with another TCA. The dose was titrated up to a maximum of 225 mg if required. Of 83 women taking a TCA at first follow-up (median 3.2 months), 59.3% improved by more than 50% compared with 38% of women not taking a TCA.

Milnacipran in provoked vestibulodynia: efficacy and predictors of treatment success

Brown C, Bachmann G, Foster D, Rawlinson L, Wan J, Ling F. *J Low Genit Tract Dis* 2015; 19: 140–4.

In this 12-week open-label trial, 22 women were treated with milnacipran, a serotonin–norepinephrine reuptake inhibitor. Milnacipran significantly reduced pain severity. The authors note that treatment success was predicted by pretreatment sexual satisfaction.

Use of amitriptyline cream in the management of entry dyspareunia due to provoked vestibulodynia

Pagano R, Wong S. *J Low Genit Tract Dis* 2012; 16: 394–7.

A prospective study of 150 patients treated with amitriptyline 2% cream twice daily for 3 months. Fifty-six percent reported symptom reduction, and 10% were completely pain free.

Overnight 5% lidocaine ointment for treatment of vulvar vestibulitis

Zolnoun DA, Hartmann KE, Steege JF. *Obstet Gynecol* 2003; 102: 84–7.

An open-label trial of 61 women treated with nightly application of 5% lidocaine ointment. Dyspareunia decreased by at least 50% in 57% of women. Seventy-six percent of patients were able to have intercourse after treatment compared with 36% before drug initiation.

Pregabalin-induced remission in a 62-year-old woman with a 20-year history of vulvodynia

Jerome L. *Pain Res Manage* 2007; 12: 212–4.

Case report of a 62-year-old woman with long-standing vulvodynia who reported 80% pain reduction after a 12-week course of oral pregabalin.

A retrospective study of the management of vulvodynia

Jeon Y, Kim Y, Shim B, Yoon H, Park Y, Shim, B, et al. Korean J Urol 2013; 54: 48–52.

Retrospective study of vulvodynia patients treated with either oral gabapentin or botulinum toxin A injections. Sixty-two women received gabapentin 300 to 900 mg/day for a period of 0.5 to 6 months. Eleven patients received intralesional botulinum toxin A injections. Significant pain reduction was reported in both groups, and both treatments were well tolerated.

Open-label trial of lamotrigine focusing on efficacy in vulvodynia

Meltzer-Brody SE, Zolnoun D, Steege JF, Rinaldi KL, Leserman J. J Reprod Med 2009; 54: 171–8.

Marked reductions in pain were noted at weeks 8 and 12 in this series involving 17 patients with generalized vulvodynia.

Topical gabapentin in the treatment of localized and generalized vulvodynia

Boardman LA, Cooper AS, Blais LR, Raker CA. Obstet Gynecol 2008; 112: 579–85.

Of 51 women included in this retrospective study, 35 patients had evaluable responses. Treatment with 2% to 6% gabapentin cream three times daily was well tolerated and led to at least 50% pain reduction in 28 of the 35 women.

Effectiveness of cognitive-behavioral therapy and physical therapy for provoked vestibulodynia: a randomized pilot study

Goldfinger C, Pukall CF, Thibault-Gagnon S, McLean L, Chamberlain S. J Sex Med 2016; 13: 88–94.

Twenty women were randomized to cognitive behavior therapy (CBT) or comprehensive physical therapy. The majority of patients in both groups reported at least 30% pain reduction, whereas improved sexual functioning was only seen in the CBT group.

Does physiotherapy treatment improve the self-reported pain levels and quality of life in women with vulvodynia? A pilot study

Forth HL, Cramp MC, Drechsler WI. J Obstet Gynaecol 2009; 29: 423–9.

A 3-month course of physiotherapy led to pain reduction in 14 women.

Second-Line Therapies

• Electromyographic (EMG) biofeedback	B
• Nitroglycerin cream	B
• Acupuncture	B
• CBT	B
• Botulinum toxin	D

EMG biofeedback versus topical lidocaine gel: a randomized study for the treatment of women with vulvar vestibulitis

Danielsson I, Torstensson T, Brodda-Jansen G, Bohm-Starke N. Acta Obstet Gynecol Scand 2006; 85: 1360–7.

Four months of treatment with EMG biofeedback or 5% lidocaine ointment led to significant improvements in pain, sexual functioning, and psychosocial adjustments in both groups. Women in the EMG biofeedback group reported low compliance and did not complete all planned practice sessions.

Safety and efficacy of topical nitroglycerin for treatment of vulvar pain in women with vulvodynia: a pilot study

Walsh KE, Berman JR, Berman LA, Vierregger K. J Gend Specif Med 2002; 5: 21–7.

This is the only report of the use of topical nitroglycerin 0.2% for the management of vulvodynia. The majority of the 21 women, who applied the cream before intercourse and completed all questionnaires, reported significant pain reduction.

Acupuncture for the treatment of vulvodynia: a randomized wait-list controlled pilot study

Schlaeger JM, Xu N, Mejta CL, Park CG, Wilkie DJ. J Sex Med 2015; 12: 1019–27.

Thirty-six women were randomly assigned to either acupuncture twice per week for 5 weeks or the control group, which consisted of

continuing their usual treatment. Vulvar pain and dyspareunia reduced significantly and sexual functioning improved in the acupuncture group.

A randomized clinical trial comparing group cognitive-behavioral therapy and a topical steroid for women with dyspareunia

Bergeron S, Khalifé S, Dupuis MJ, McDuff P. J Consult Clin Psychol 2016; 84: 259–68.

This 13-week trial included 97 women with provoked vestibulodynia. Fifty-two were randomized to group CBT and 45 to hydrocortisone 1% cream. Both groups reported significant improvements in pain and sexual functioning after treatment and at 6-month follow-up; however, these effects were significantly greater in the CBT group.

Botulinum toxin type A: a novel treatment for provoked vestibulodynia? Results from a randomized, placebo controlled, double blinded study

Petersen CD, Giraldi A, Lundvall L, Kristensen E. J Sex Med 2009; 6: 2523–37.

Sixty-four women were randomized to receive 20 units botulinum toxin A or placebo injections; 60 completed the 6 months, follow-up. Significant pain reduction was reported in both groups, but there were no statistically significant differences.

The nonsuperiority of botulinum toxin A in this study may be due to the low dose used, compared with the next study.

Long-term assessment of effectiveness and quality of life of OnabotulinumtoxinA injections in provoked vestibulodynia

Pelletier F, Girardin M, Humbert P, Puyraveau M, Aubin F, Parratte B. J Eur Acad Dermatol Venereol 2016; 30: 106–11.

Nineteen patients who had received bilateral onabotulinumtoxinA injections (total of 100 units) into the bulbospongiosus muscles completed questionnaires 2 years after treatment. Pain, sexual function, and quality of life improved significantly, and 37% were pain free at 24 months. Eighteen of the 19 women had avoided intercourse before the treatment and were able to resume intercourse after treatment.

Third-Line Therapies

• Enoxaparin	A
• Transcutaneous electrical nerve stimulation (TENS)	A
• Cultured fibroblasts	A
• Surgery	B
• Capsaicin	D
• Fractional CO ₂ laser	D
• Multilevel local anesthetic nerve blockade	D
• Hypnosis	E
• Spinal cord stimulator	E
• Nutrition therapy	E
• Radiofrequency therapy	E
• Peripheral subcutaneous vulvar stimulation	E

Enoxaparin treatment for vulvodynia: a randomized controlled trial

Farajun Y, Zarfati D, Abramov L, Livoff A, Bornstein J. Obstet Gynecol 2012; 120: 565–72.

In this randomized, double-blind study, 40 women with localized, provoked vulvodynia self-administered enoxaparin, a low-molecular-weight heparin, or placebo via subcutaneous injection once daily for 90 days. Reduction of pain and dyspareunia were greater in the enoxaparin group.

Vestibulodynia: synergy between palmitoylethanolamide + transpodydatin and transcutaneous electrical nerve stimulation

Murina F, Graziottin A, Felice R, Radici G, Tognocchi C. J Low Genit Tract Dis 2013; 17: 111–6.

In a double-blind, placebo-controlled study, 20 patients were

randomized to oral palmitoylethanolamide (PEA) 400 mg and polydatin 40 mg or placebo twice daily for 60 days. All patients also self-administered TENS therapy three times weekly. There was significant improvement in both groups.

Transcutaneous electrical nerve stimulation as an additional treatment for women suffering from therapy-resistant provoked vestibulodynia: a feasibility study

Vallinga MS, Spoelstra SK, Hemel IL, van de Wiel HB, Weijmar Schultz WC. J Sex Med 2015; 12: 228–37.

Thirty-nine women applied domiciliary TENS three times daily. There were significant reductions in vulvar pain directly after treatment and at follow-up (between 2 and 32 months), with improvements in sexual functioning.

Cream with cutaneous fibroblast lysate for the treatment of provoked vestibulodynia: a double-blind randomized placebo-controlled crossover study

Donders GG, Bellen G. J Low Genit Tract Dis 2012; 16: 427–36.

In this crossover study, 30 patients were randomized 1:1 to a topical lysate of cultured human fibroblasts or placebo. There was statistically significant reduction in dyspareunia with treatment, with no improvement with placebo use.

A randomized comparison of group cognitive-behavioral therapy, surface electromyographic biofeedback, and vestibulectomy in the treatment of dyspareunia resulting from vulvar vestibulitis

Bergeron S, Binik YM, Khalife S, Pagidas K, Glazer HI, Meana M, et al. Pain 2001; 91: 297–306.

In this study comparing group CBT, EMG biofeedback, and vestibulectomy, 78 women were randomly assigned to a treatment. Significant improvements in pain measures were reported in all three groups. Although pain reduction was more significant in the vestibulectomy group, seven women assigned to this treatment declined the intervention.

Localized provoked vestibulodynia: outcomes after modified vestibulectomy

Swanson CL, Rueter JA, Olson JE, Weaver AL, Stanhope CR. J Reprod Med 2014; 59: 121–6.

A total of 202 women treated with modified vestibulectomy at the Mayo Clinic were sent a questionnaire. A total of 90.4% of the 52 patients who reported pain with tampon insertion before surgery reported moderate to substantial pain reduction after surgery, and 84.1% of the 107 women who complained of dyspareunia noted significant improvement.

Capsaicin and the treatment of vulvar vestibulitis syndrome: a valuable alternative?

Murina F, Radici G, Bianco V. MedGenMed 2004; 6: 48.

Thirty-three women applied capsaicin cream 0.05% twice daily for 30 days, then daily for 30 days, followed by twice weekly for 4 months. Fifty-nine percent reported a partial response, with relapse after cessation. All patients complained of severe burning as a side effect.

Before the application of capsaicin, patients applied topical lidocaine to avoid irritation. It is therefore unclear how much of the effect can be attributed to capsaicin.

Fractional CO₂ laser treatment of the vestibule for patients with vestibulodynia and genitourinary syndrome of menopause: a pilot study

Murina F, Karram M, Salvatore S, Felice R. J Sex Med 2016; 13: 1915–7.

This study included 37 patients who underwent three sessions of fractional microablative CO₂ laser treatment. Pain scores and dyspareunia improved significantly over 4 months, and the treatments were well tolerated.

Multilevel local anesthetic nerve blockade for the treatment of generalized vulvodynia: a pilot study

McDonald JS, Rapkin AJ. J Sex Med 2012; 9: 2919–26.

Twenty-six women completed all five multilevel local anesthetic nerve blocks at 2-week intervals. At follow-up 2 to 3 months later, there was significant improvement in vulvar pain and depression, but no changes in sexual functioning. Women with more severe pain at baseline had less improvement.

Effectiveness of hypnosis for the treatment of vulvar vestibulitis syndrome: a preliminary investigation

Pukall C, Kandyba K, Amsel R, Khalife S, Binik Y. J Sex Med 2007; 4: 417–25.

Six hypnotherapy sessions led to significant improvements in pain and sexual functioning in eight women.

Spinal cord stimulator for the treatment of a woman with vulvovaginal burning and deep pelvic pain

Nair AR, Klapper A, Kushnerik V, Margulis I, Del Priore G. Obstet Gynecol 2008; 111: 545–7.

Implantation of a spinal cord stimulator led to significant improvement in vulvodynia in a 57-year-old woman.

Vulvodynia and irritable bowel syndrome treated with an elimination diet: a case report

Drummond J, Ford D, Daniel S, Meyerink T. Integr Med (Encinitas) 2016; 15: 42–7.

A young woman with refractory vulvodynia and irritable bowel syndrome was treated with an elimination diet. During the 6 months of nutrition therapy, her pelvic pain decreased markedly.

Radiofrequency therapy for severe idiopathic vulvodynia

Kestřánek J, Špaček J, Ryška P, Adamkov J, Matula V, Buchta V. J Low Genit Tract Dis 2013; 17: e1–4.

Report of patient who responded to pulsed radiofrequency treatment of the hypogastric ganglion. Her pain reduced significantly for a period of around 6 months.

Peripheral subcutaneous vulvar stimulation in the management of severe and refractory vulvodynia

De Andres J, Sanchis-Lopez N, Asensio-Samper JM, Fabregat-Cid G, Dolz VM. Obstet Gynecol 2013; 121: 495–8.

Two vulvar subcutaneous electrodes were implanted in a young woman with refractory vulvodynia who underwent peripheral subcutaneous vulvar field stimulation. Pain scores reduced significantly posttreatment and at 12 months, follow-up.

Wells syndrome

Wisam Alwan, Emma Benton, and Ian Coulson

Wells syndrome (eosinophilic cellulitis) is a rare condition resembling a bacterial cellulitis. Patients are often treated with antibiotics and fail to respond before the diagnosis of Wells syndrome is considered and then confirmed on skin biopsy. Although the precise etiology is unknown, there are several disease associations,

including drug-induced disease. It is postulated that Wells syndrome represents a hypersensitivity reaction to a variety of stimuli, both endogenous and exogenous. The condition can be recurrent, and although thought to be sporadic, familial patterns have been reported. The most common clinical manifestations are erythematous patches and plaques, but papulonodular and bullous types of Wells syndrome have been described. Characteristic histologic features include dermal edema with a marked eosinophilic infiltrate and flame figures (representing deposition of eosinophilic proteins and degradation products onto collagen fibers), although this is not specific to the condition. The usual course is of a pruritic sensation, followed rapidly by indurated, erythematous plaques of edema with violaceous edges that can form blisters. The lesions progress over a few days, resolving without scarring within 8 weeks. There is no anatomic predilection for plaques, and they may be solitary or multiple.

Management Strategy

Although there is no known cause, several precipitating factors have been suggested ([Table 255.1](#)). Some of the associations are well reported, others anecdotal. Injection site skin lesions have been associated with the tumor necrosis factor antagonists etanercept and adalimumab and also with interferon-beta. Interestingly, adalimumab has also been successfully used to treat refractory Wells syndrome in two cases. Minocycline can also induce a Wells syndrome-like disorder.

Suspect culprit drugs should be withdrawn. If an underlying systemic disease is identified, this will require treatment in its own right. Many cases of Wells syndrome associated with internal malignancy resolved with treatment of the initial tumor.

The most frequently reported therapy is with *systemic (oral) corticosteroids*, used at moderate doses to gain control of symptoms, followed by tapering. Cases may resolve spontaneously. As with bullous pemphigoid, localized disease may respond to *superpotent topical steroids*. Topical *tacrolimus* has also been used successfully. The H₁ antihistamine with antieosinophil action *cetirizine* has been effective; levocetirizine and hydroxyzine in combination have also proven successful. *Minocycline*, *dapsone*, *antimalarials*, *griseofulvin*, *adalimumab*, and *ciclosporin* are anecdotally beneficial.

Specific Investigations

- Peripheral blood eosinophil count
- Skin biopsy
- Look for known associations of the disease

Wells syndrome: a clinical and histopathologic review of seven cases

Moossavi M, Mehregan DR. Int J Dermatol 2003; 42: 62–7.

Eosinophilic cellulitis-like reaction to subcutaneous etanercept injection

Winfield H, Lain E, Horn T, Hoskyn J. Arch Dermatol 2006; 142: 218–20.

Eosinophilic cellulitis (Wells syndrome) as a cutaneous reaction to the administration of adalimumab

Boura P, Sarantopoulos A, Lefaki I, Skendros P, Papadopoulos P. Ann Rheum Dis 2006; 65: 839–40.

Systemic lupus erythematosus associated with Wells syndrome

Yin G, Xie Q. Rheumatol Int 2012; 32: 1087–9.

Wells syndrome associated with Churg–Strauss syndrome

Fujimoto N, Wakabayashi M, Kato T, Nishio C, Tanaka T. Clin Exp Dermatol 2011; 36: 46–8.

Wells' syndrome associated with chronic myeloid leukemia

Nakazato S, Fujita Y, Hamade Y, Nemoto-Hasebe I, Sugita J, Nishie W, et al. Acta Derm Venereol 2013; 93: 375–6.

Bullous eosinophilic cellulitis associated with giardiasis

Aslam A, Salman W, Chaudhry IH, Coulson IH, Owen CM. Clin Exp Dermatol 2014; 39: 264–5.

Eosinophilic cellulitis (Wells syndrome) caused by a temporary henna tattoo

Nacaroglu HT, Celegen M, Karkiner CS, Günay I, Diniz G, Can D. Postepy Dermatol Alergol 2014; 31: 322–4.

Influenza vaccination as a novel trigger of Wells syndrome in a child

Simpson JK, Patalay R, Francis N, Roberts N. *Pediatr Dermatol* 2015; 32: e171–2.

Other conditions anecdotally associated with Wells syndrome include chronic lymphocytic leukemia, angioimmunoblastic lymphadenopathy, adenocarcinoma of the lung, gastric cancer, renal (clear cell) cancer, colon cancer, botryomycosis, molluscum contagiosum, celiac disease, and ulcerative colitis. Some of the associations are based on single case reports and may be coincidental.

Table 255.1

Reported associations with eosinophilic cellulitis

Infections: bacterial, viral (HIV, herpes simplex, parvovirus, varicella, molluscum contagiosum), parasitic (*Ascaris*, toxocariasis, giardiasis)
Insect bite reactions
Ulcerative colitis
Leukemia
Lymphoma
Solid cancers (lung, colon, gastric, renal)
Angioimmunoblastic lymphadenopathy
Hypereosinophilic syndrome
Drugs (including vaccines, particularly those containing thimerosal)
Churg–Strauss syndrome
Allergic asthma exacerbation
Systemic lupus erythematosus
Metallic alloy implants
Celiac disease
Allergic contact dermatitis (paraphenylenediamine [PPD] and black rubber in temporary henna tattoo)
IgG4-related disease

First-Line Therapy

• Oral corticosteroids	C
------------------------	---

Recurrent granulomatous dermatitis with eosinophilia

Wells GC. Trans St Johns Hosp Dermatol Soc 1971; 57: 46–56.

Eosinophilic cellulitis

Wells GC, Smith NP. Br J Dermatol 1979; 100: 101–9.

Wells' first publications on the disease. Oral prednisolone, ranging in doses of 20 to 40 mg/day, is a reasonable starting point, tapering the dose until control and hopefully resolution. One month of tapering prednisolone has been used successfully in patients.

Second-Line Therapies

• Cetirizine	E
• Levocetirizine/hydroxyzine	E
• Ciclosporin	E
• Dapsone	E
• Interferon- α	E
• Minocycline	E
• Sulfasalazine	E
• Griseofulvin	E
• Tacrolimus	E
• Adalimumab	E

Eosinophilic cellulitis in a child successfully treated with cetirizine

Aroni K, Aivaliotis M, Liossi A, Davaris P. Acta Derm Venereol 1999; 79: 332.

Treatment of Wells syndrome in children with corticosteroids risks concerns regarding growth retardation, and the authors described a child successfully treated with cetirizine 10 mg daily.

Cetirizine 10 to 30 mg daily is a reasonable consideration in adults.

Eosinophilic cellulitis (Wells syndrome) successfully treated with low-dose ciclosporin

Herr H, Koh JK. J Korean Med Sci 2001; 16: 664–8.

A report of ciclosporin use in an adult with Wells syndrome; 2.5 to 5 mg/kg/day was used.

Eosinophilic cellulitis case report: treatment options

Lee MW, Nixon RL. *Australas J Dermatol* 1994; 35: 95–7.

Dapsone was added to oral steroids and antihistamines as a steroid-sparing agent as monotherapy with steroids alone gained inadequate control.

Doses of 50 to 150 mg/day would be an appropriate trial.

Interferon alfa treatment of a patient with eosinophilic cellulitis and HIV infection

Husak R, Goerdts S, Orfanos CE. *N Engl J Med* 1997; 337: 641–2.

Failure to control HIV-associated Wells syndrome with steroids prompted a successful trial of interferon- α treatment.

Eosinophilic cellulitis (Wells syndrome): treatment with minocycline

Stam-Westerveld EB, Daenen S, Van der Meer JB, Jonkman MF. *Acta Derm Venereol* 1998; 78: 157.

Minocycline 200 mg daily was used to control disease, and 100 mg daily was used as maintenance.

Oral tacrolimus treatment for refractory eosinophilic cellulitis

Ohtsuka T. *Clin Exp Dermatol* 2009; 34: 597–8.

The authors report a case of eosinophilic cellulitis that previously had been responsive to oral corticosteroids (prednisolone 15 mg/day). The patient failed to respond to this treatment on recurrence and was successfully treated with oral tacrolimus (1 mg/day).

Wells' syndrome mimicking facial cellulitis: a report of two cases

Cormerais M, Poizeau F, Darrieux L, Tisseau L, Safa G. *Case Rep Dermatol*. 2015; 9: 117–22.

The authors highlighted two patients who experienced no relapse during follow-up of between 3 and 12 months using levocetirizine 10 mg daily and hydroxyzine 50 mg daily.

Treatment of recalcitrant eosinophilic cellulitis with adalimumab

Sarin KY, Fiorentino D. *Arch Dermatol* 2012; 148: 990–2.

A 45-year-old woman with a 10-year history of Wells syndrome

was unable to tolerate full-dose oral prednisolone and did not respond to systemic agents, including antihistamines, azathioprine, dapsone, and colchicine. The patient responded to fortnightly adalimumab.

Off-label use of TNF-alpha inhibitors in a dermatologic university department: retrospective evaluation of 118 patients

Sand FL, Thomsen SF. *Dermatol Ther* 2015; 28: 158–65.

The authors reported an elderly female patient with total clearance of disease on 6 months of adalimumab.

Xanthomas

Lucile E. White, Marcelo G. Horenstein, and Christopher R. Shea

Xanthomas are flat, yellow plaques or nodules consisting of abnormal lipid deposits. Clinically, xanthomas can be classified as eruptive, tuberoeruptive, tuberous, tendinous, verruciform, or plane. Plane xanthomas are the most common and include xanthelasma palpebrarum, xanthoma striatum palmare, and intertriginous xanthomas. Verruciform xanthomas typically affect genital skin and may be a consequence of lymphedema. Necrobiotic xanthogranulomas are scarring, commonly ulcerated nodules with a predilection for the periorbital areas and are associated with paraproteinemia.

Management Strategy

Xanthomas may be idiopathic or a sign of underlying hyperlipidemia. *Diagnosing and treating the underlying disease* are necessary not only to decrease the size of the xanthomas but also to reduce the risk of atherosclerosis associated with lipoprotein disorders. Treatment of the hyperlipidemia initially consists of *diet and lipid-lowering agents* such as statins, fibrates, bile acid-binding resins, probucol, or nicotinic acid. The lipid-lowering effects of these agents have been well documented, but few studies document the efficacy of these drugs at resolving xanthomas. Anecdotally, eruptive xanthomas typically appear to resolve within weeks of initiating systemic treatment, and tuberous xanthomas after some months, but tendinous xanthomas may take years to resolve or even persist indefinitely. *Surgery or locally destructive modalities* can be used for idiopathic or unresponsive xanthomas.

Specific Investigations

- Serum lipid panel of cholesterol, triglycerides, VLDL, LDL, and HDL
- Gas-liquid and high-performance liquid chromatography to diagnose sitosterolemia
- Capillary gas chromatography of urine to diagnose cerebrotendinous xanthomatosis
- Serum protein electrophoresis, immunoelectrophoresis, or immunofixation to detect M proteins

Excluding an underlying condition is essential in the management of most clinical forms of xanthomas. Eruptive xanthomas typically occur in the setting of hypertriglyceridemia. Hypertriglyceridemia can be the result of lipoprotein lipase deficiency, familial hyperlipoproteinemia, or secondary causes such as diabetes mellitus, alcohol ingestion, or exogenous estrogens. Tuberoeruptive and tuberous xanthomas represent parts of a spectrum and are seen most commonly in the setting of familial dysbetalipoproteinemia. Tuberous xanthomas may also be a presentation of homozygous familial hypercholesterolemia, cerebrotendinous xanthomatosis (associated with neuropsychiatric symptoms), or sitosterolemia. Patients with sitosterolemia and cerebrotendinous xanthomatosis may have normal

serum lipid panels; therefore diagnosis may require liquid chromatography for plant sterols or urinary gas chromatography. Tendinous xanthomas may also occur with cerebrotendinous xanthomatosis, sitosterolemia or, more commonly, heterozygous familial hypercholesterolemia. Certain xanthomas are diagnostic for an inherited hyperlipidemia: xanthoma striatum palmare for familial dysbetalipoproteinemia and intertriginous xanthomas for homozygous familial hypercholesterolemia. Even in the presence of these classic presentations, a serum lipid panel is still indicated to confirm the diagnosis.

Regarding xanthelasma palpebrarum, a type of plane xanthoma, levels of total cholesterol are elevated in only about half of patients; however, patients with xanthelasma may have elevated apolipoprotein B and decreased apolipoprotein A1 levels, as well as subclinical increases in carotid intima-media thickness. Moreover, xanthelasma is a risk factor for myocardial infarction, ischemic heart disease, severe atherosclerosis, and death, independently of plasma cholesterol and triglyceride concentrations. Less commonly, plane xanthomas can signal a monoclonal gammopathy. In this situation, the differential diagnosis of necrobiotic xanthogranuloma with paraproteinemia, a condition usually associated with lymphoproliferative disorders, should be considered.

First-Line Therapies

• Low-fat diet and systemic lipid-lowering therapy	B
--	----------

Opposite effects on serum cholesteryl ester transfer protein levels between long-term treatments with pravastatin and probucol in patients with primary hypercholesterolemia

Inazu A, Koizumi J, Kajinami K, Kiyohar T, Chichibu K, Mabuchi H. *Atherosclerosis* 1999; 145: 405–13.

This prospective study examined whether pravastatin or probucol was better at regressing tendon xanthomas and xanthelasma in patients with primary hypercholesterolemia. In both the pravastatin and probucol groups, xanthelasma regressed in two of four patients. Achilles tendon xanthoma regressed in four of five patients treated

with pravastatin and two of five patients on probucol.

A comparative study of the therapeutic effect of probucol and pravastatin on xanthelasma

Fujita M, Shirai K. *J Dermatol* 1996; 23: 598–602.

Fifty-four patients were treated with probucol or pravastatin. Xanthelasmas regressed in 13 of 36 patients treated with probucol and 1 of 18 patients treated with pravastatin.

Effects of probucol on xanthomata regression in familial hypercholesterolemia

Yamamoto A, Matsuzawa Y, Yokoyama S, Funahashi T, Yamamura T, Kishino B. *Am J Cardiol* 1986; 57: H29–35.

Fifty one patients, including eight homozygotes, were treated with combinations of probucol, cholestyramine, clofibrate, and compactin. Achilles tendon xanthomas shrank in all patients who received probucol. Probucol possibly reduces the size of HDL particles, increasing reverse cholesterol transport.

Successful treatment of xanthoma disseminatum with combined lipid lowering agents

Kim WJ, Ko HC, Kim BS, Kim MB. *Ann Dermatol* 2012; 24: 380–2.

Combination therapy with rosiglitazone 4 mg daily, simvastatin 10 mg daily, and fenofibrate 200 mg daily resulted in notable reduction of the skin lesions persisting 2 years later.

Second-Line Therapies

• Surgery	B
• CO ₂ laser	B
• Erbium:YAG laser	C
• Pulsed dye laser	B
• Argon laser	B
• Q-switched Nd:YAG laser	D
• KTP laser	D
• 1450-nm diode laser	C
• Low-voltage radiofrequency	C

Treatment of xanthelasma by excision with secondary intention healing

Eedy DJ. Clin Exp Dermatol 1996; 21: 273–5.

Xanthelasmas were removed in 28 patients by scissor excision. After 18 months, two patients, one with hypercholesterolemia and one with primary biliary cirrhosis, had recurrence. One patient developed scarring. No ectropion developed.

Upper and lower eyelid reconstruction for severe disfiguring necrobiotic xanthogranuloma

Schaudig U, Al-Samir K. Orbit 2004; 23: 65–76.

Severe cicatricial eyelid deformation caused by necrobiotic xanthogranuloma can be treated successfully by excision and free skin grafting.

Successful treatment of scrotal verruciform xanthoma with shave debulking and fractionated carbon dioxide laser therapy

Joo J, Fung MA, Jagdeo J. *Dermatol Surg* 2014; 40: 214–7.

A patient treated with combined shave debulking and fractionated CO₂ laser ablation. The procedure was well tolerated, and no recurrence was noted at 18 months.

Xanthelasma palpebrarum: treatment with the ultrapulsed CO₂ laser

Raulin C, Schoenermark MP, Werner S, Greve B. *Lasers Surg Med* 1999; 24: 122–7.

Ultrapulsed CO₂ laser delivers high energy in short pulses and reduces the risk of scarring and hyperpigmentation seen with continuous-mode CO₂ lasers. Twenty-three patients with 52 xanthelasmas were treated. All xanthelasmas were removed completely. No permanent hyperpigmentation or ectropion developed.

Xanthelasma palpebrarum: treatment with the erbium:YAG laser

Borelli C, Kaudewitz P. *Lasers Surg Med* 2001; 29: 260–4.

Fifteen patients with 33 xanthelasmas were treated with an Er:YAG laser at settings between of 300 mJ, 2 Hz for a 2-mm spot size and 1200 mJ, 6 Hz for a 10-mm spot size. All xanthelasmas were removed completely. Postoperative erythema resolved within 2 weeks. No scarring or ectropion developed. No lesions recurred over a 7- to 12-month follow-up period.

New operative technique for treatment of xanthelasma palpebrarum: laser-inverted resurfacing. Preliminary report

Levy JL, Trelles MA. *Ann Plast Surg* 2003; 50: 339–43.

The authors propose use of pulsed Er:YAG vaporization of the lipomatous tissue off the inner surface of the eyelid after incision and eversion of the incised tissue to expose the xanthelasma. In two patients treated by this technique no recurrence was seen in up to 1 year of follow-up.

Treatment of xanthelasma palpebrarum by 1064-nm Q-switched Nd:YAG laser: a study of 11 cases

Fusade T. *Br J Dermatol* 2008; 158: 84–7.

Results after even a single treatment were reported to be good or excellent in 8 of 11 patients (in 26 of 38 lesions), and healing was rapid.

Is Q-switched neodymium-doped yttrium aluminium garnet laser an effective approach to treat xanthelasma palpebrarum? Results from a clinical study of 76 cases

Karsai S, Schmitt L, Raulin C. *Dermatol Surg* 2009; 35: 1962–9.
Most lesions failed to respond.

Treatment of xanthelasma palpebrarum with argon laser photocoagulation

Basar E, Oguz H, Oxdemir H, Ozkan S, Uslu H. *Int Ophthalmol* 2004; 25: 9–11.

Twenty-four patients with 40 xanthelasmas were treated with an argon laser at settings of 500 μm , 0.1 to 0.2 s, and 900 mW. Complete removal of all lesions occurred with one to four sessions at intervals of 2 or 3 weeks. Six lesions recurred over 8 to 12 months and required retreatment. Erythema persisted for 1 month in 8 lesions. Hyperpigmentation occurred in one patient and persisted for 3 months, whereas hypopigmentation occurred in 2 lesions.

Histopathological study of xanthelasma palpebrarum after pulsed dye laser

Soliman M. *J Eur Acad Dermatol Venereol* 2004; 18 (Suppl): 19–33.

Twenty-six patients were treated with fluences ranging from 6.5 to 8 J/cm², a spot size of 5 mm, and a pulse width of 450 ms. All experienced very good to excellent clinical improvement with one to three treatments at 3- or 4-week intervals.

KTP laser coagulation for xanthelasma palpebrarum

Berger C, Kopera D. *J Dtsch Dermatol Ges* 2005; 3: 775–9.

The authors employed the KTP laser (532 nm) to treat 14 patients. Over 70% tolerated laser irradiation without analgesia; 85.7% showed reduction of lesions after one to three treatment sessions, without reported side effects.

Xanthelasma palpebrarum treatment with a 1450-nm-diode laser

Park EJ, Youn SH, Cho EB, Lee GS, Hann SK, Kim KH, et al. *Dermatol Surg* 2011; 37: 791–6.

Sixteen patients received one to four treatments using a 1450-nm diode laser at 12 J/cm², 6-mm spot size, and 20 to 30 ms. Twelve patients experienced moderate to marked improvement. The treatment was well tolerated.

Effectiveness of low-voltage radiofrequency in the treatment of xanthelasma palpebrarum: a pilot study of 15 cases

Dincer D, Koc E, Erbil AH, Kose O. Dermatol Surg 2010; 36: 1973–8.

Fifteen patients were treated by superficial application of electrodes from a dual-frequency 4.0-MHz radiofrequency machine. All subjects completed the study; excellent results were achieved in 9 patients and good results in 5 patients.

Third-Line Therapies

• Di- or trichloroacetic acid	C
• Cryotherapy	E
• Bleomycin	B
• Intralesional triamcinolone acetonide	D
• Chlorambucil	E
• Prednisolone	E
• Intravenous immunoglobulin	E
• Anakinra	E
• 2-chlorodeoxyadenosine (cladribine)	E
• Topical imiquimod	E
• Bexarotene	E

Evaluation of three different strengths of trichloroacetic acid in xanthelasma palpebrarum

Haque MU, Ramesh V. J Dermatolog Treat 2006; 17: 48–50.

Three strengths of trichloroacetic acid (TCA) were tested on 51 patients. For papulonodular lesions, on average approximately two applications were required with 100% or 70% TCA versus approximately four applications with 50% TCA. For flat plaques an average of approximately 1.5 applications of 100% or 70% TCA sufficed, versus approximately 3 applications with 50% TCA. Macular lesions responded to a single application of all strengths of TCA studied.

Cryotherapy may be effective for eyelid xanthoma

Hawk JL. Clin Exp Dermatol 2000; 25: 351.

One patient was treated with liquid nitrogen applied for 0.5 to 1 s. Treatment was carefully limited to only the yellow areas. Previous treatment with TCA had been unsuccessful.

Treatment of xanthelasma palpebrarum with intralesional pingyangmycin

Wang H, Shi Y, Guan H, Liu C, Zhang W, Zhang Y, et al. Dermatol Surg 2016; 42: 368–76.

Twelve patients with xanthelasma palpebrarum had a total of 21 lesions injected with intralesional pingyangmycin (bleomycin A5). All patients except one received satisfactory results, and only one patient experienced a local recurrence, 1 year after the treatment. No severe complications were identified.

Local corticosteroid treatment of eyelid and orbital xanthogranuloma

Elnar VM, Mintz R, Demirci H, Hassan AS. Trans Am Ophthalmol Soc 2005; 103: 69–73.

Six patients received two intralesional injections of triamcinolone acetonide (40 mg/mL) for eyelid and orbital necrobiotic xanthogranuloma (four patients) or adult-onset xanthogranuloma (two patients). Local control was obtained in all six cases with no complications noted.

Necrobiotic xanthogranuloma treated with chlorambucil

Torabian SZ, Fazel N, Knuttel R. Dermatol Online J 2006; 12: 11.

A 56-year-old man with a 5-year history of multiple necrobiotic xanthogranulomas involving the periorbital area, extremities, and trunk was treated with chlorambucil at 2 mg/day, later increased to 4 mg/day, which resulted in complete resolution of the lesions.

Necrobiotic xanthogranuloma of extremities in an elderly patient successfully treated with low-dose prednisolone

Kawakami Y, Yamamoto T. *Dermatol Online J* 2011; 17: 13.

A 93-year-old woman with an IgG λ paraproteinemia and ulcerated, tender necrobiotic xanthogranulomas involving the left lower leg experienced resolution 4 weeks after starting treatment with oral prednisolone, 20 mg daily (0.5 mg/kg).

Successful treatment of necrobiotic xanthogranuloma with intravenous immunoglobulin

Hallermann C, Tittelbach J, Norgauer J, Ziemer M. *Arch Dermatol* 2010; 146: 957–60.

Two patients with necrobiotic xanthogranuloma and monoclonal gammopathy responded well to intravenous immunoglobulin, 0.5 g/kg/day, administered for 4 consecutive days at 4-week intervals.

Cerebral and cutaneous involvements of xanthoma disseminatum successfully treated with an interleukin-1 receptor antagonist: a case report and minireview

Campero M, Campero S, Guerrero J, Aouba A, Castro A. *Dermatology* 2016; 232: 171–6.

One patient with xanthoma disseminatum, including skin and brain lesions, received anakinra 100 mg subcutaneously daily, continued on a weekly dose for 2 years, and then as a monthly dose for 1 year. All skin lesions disappeared within 15 months, and there was a notable reduction in lesions of the brainstem, temporal lobes, and caudate nucleus; the patient remained asymptomatic at 5-year follow-up.

Xanthoma disseminatum: effective therapy with 2-chlorodeoxyadenosine in a case series

Khezri F, Gibson LE, Tefferi A. *Arch Dermatol* 2011; 147: 459–64.

Five patients received 2-chlorodeoxyadenosine at 0.14 mg/kg/day for 5 days, repeated monthly for five to eight treatment cycles. After three to five cycles, new mucocutaneous lesions stopped developing

in all patients, and all patients had substantial improvement in established lesions. No serious adverse effects were reported. At follow-up ranging from 3 months to 8 years, all patients had achieved remission.

Successful treatment of verruciform xanthoma with imiquimod

Guo Y, Dang Y, Toyohara JP, Geng S. *J Am Acad Dermatol* 2013; 69: e184–6.

A 2-year-old girl with verruciform xanthoma on the vulva and around the anus received topical imiquimod cream 5% twice a week; the lesions almost entirely cleared 4 months later and remained in remission 9 months later.

Treatment of mycosis fungoides with bexarotene results in remission of diffuse plane xanthomas

Gregoriou S, Rigopoulos D, Stamou C, Nikolaou V, Kontochristopoulos G. *J Cutan Med Surg* 2013; 17: 52–4.

A patient with mycosis fungoides (MF) and plane xanthomas was treated with bexarotene for MF. Complete clinical remission of both the MF and the xanthomas was noted after 6 months, and the patient remained free of xanthomas after 3 years.

Xeroderma pigmentosum

Deborah Tamura, Kenneth H. Kraemer, and John J. DiGiovanna

Xeroderma pigmentosum (XP) is a rare autosomal recessive disorder characterized by cellular hypersensitivity to the damaging

effects of ultraviolet (UV) radiation, resulting in a 10,000-fold increased risk of skin cancers that often develop in the first decade of life. About half of patients present with acute photosensitivity to minimal sun exposure, resulting in severe erythema and blistering. Burns can be so severe that child abuse or neglect is suspected. The other half of the patients do not have these acute reactions and often develop early frecklelike pigmentation before age 2 years. This may be accompanied by a dry “aged” appearance to the skin, cheilitis, and photophobia. The eyes are particularly vulnerable, and damage may include dry eye, ectropion, pterygia, pinguecula, corneal clouding, and scarring leading to blindness; in addition they can develop cancer of the lids, sclera, or cornea. Cancers can also occur on the lips and tip of the tongue. Approximately 25% of XP patients develop a progressive neurodegeneration with loss of deep tendon reflexes, progressive sensorineural hearing loss, dysphagia and dysarthria, ataxia, and early demise.

The progressive skin and eye damage is due to an inability to repair UV-induced DNA damage in sun-exposed tissues. XP patients have mutations in one of eight genes. Seven (*XPA*, *XPB*, *XPC*, *XPD*, *XPE*, *XPF*, or *XPG*) are in the nucleotide excision repair (NER) pathway, and the other is DNA polymerase eta (XP variant). The NER pathway is critical for the identification, removal, and repair of UV-induced DNA damage, and polymerase eta bypasses unrepaired DNA damage.

Management Strategy

The diagnosis of XP is based on clinical features, and once suspected UV protection should be initiated immediately. XP should be suspected in a child with a history of freckling on sun-exposed skin before age 2 years, severe sunburn after minimal sun exposure, photophobia, or cancer of the skin or eye. Disorders that should be excluded include porphyria, lupus, LEOPARD syndrome, Carney complex, familial melanoma, and nevoid basal cell carcinoma syndrome.

DNA testing for mutations in several XP genes is available (www.genetests.org). Because XP is foremost a clinical diagnosis and mutation testing may not identify all XP gene mutations, failure to identify a mutation does not rule out the diagnosis of XP. The cells of XP patients in culture are extremely sensitive to the killing effects of

UV, but there are currently no Clinical Laboratory Improvement Amendments (CLIA)-certified laboratories in the United States performing this type of cell survival XP test.

The most critical management goal for XP is UV protection. Although XP patients do not repair damage from UV exposure of tissues, they react normally to visible light. Eradicating all exposure to UV radiation may not be attainable; efforts should be directed toward providing a safer environment. Environments with high UV levels, such as outdoors during daylight hours, require the most rigorous protection and avoidance. However, long periods of lower levels of exposure also cause the accumulation of UV damage. We can sense differences in the intensity of visible light (e.g., less during a hazy day); however, our senses do not perceive UV and can be misled without the assistance of a UV meter. Patients and their families can be taught to recognize and avoid UV sources and to institute protective measures in their home, school, and other areas where the patient will spend long periods.

Protective measures should be a daily routine for XP patients. These include topically applied broad-spectrum sun preparations with an SPF (sun protection factor) of at least 30 or higher that protect against both UVB (short-wavelength UV 290–320 nm) and UVA (long-wavelength UV 320–400 nm) and sun-protective lip balms and/or makeup. The first application of the day should cover all exposed skin surface areas, and applications should be reapplied to uncovered skin (usually face, ears, neck, and hands) several times during the day. Finding the most acceptable sun block may take trial and error.

Clothing should cover as much skin surface as possible including long pants, long-sleeved shirts, socks and closed-toe shoes, hats that cover the ears or UV-blocking face shields and hoods, and UV-blocking sunglasses with side shields. For daytime outdoor exposure gloves or mittens can be worn to protect hands. Clothing material should be tightly woven (e.g., denim) or double layered. A simple test of effective UV protection by clothing is to hold the material up to a bright light. Material that permits visible light to pass will not block UV. Commercially available clothing made from sun-blocking material is available but may be expensive. One alternative is a laundry additive called SunGuard

(<https://sunguardsunprotection.com/index.php>), which is advertised to increase the ability of clothing to block UV. They recommend regular washing of outer clothing (pants, shirts, jackets, socks, gloves,

and hats) to increase UV protection. Because the cornea, sclera, and supporting tissues are also at risk, XP patients should wear UV-blocking sunglasses when in areas of potential exposure. The glasses should “wrap around” the eyes to protect the sides of the eyes and be large enough to fully protect both lids. Rigorous use of these measures should be initiated as soon as the diagnosis of XP is suspected and need to be the mainstay of lifelong protection.

The major source of UV is the sun. Although window glass blocks most UVB wavelengths, UVA can pass through glass (along with visible light). Extremely sensitive XP patients have burned through window glass. The Americans with Disability Act and other laws and regulations mandate that children and adults with XP be provided *safe educational and working environments*. Windows in rooms where XP patients will be spending substantial amounts of time, such as at home, in a car, in day care, school, and work, should be shielded from UV radiation. This can be done with clear UV protective film or, in some cases, by creating a consistently safe distance from windows. Schools should make accommodations during fire drills and physical education activities, because leaving the building during these activities is not safe for children with XP. An Individualized Educational Plan (IEP) should be developed to keep them protected from UV sources while encouraging interaction with other students.

Medical alert bracelets

(<http://www.medicalert.org/home/Homegradient.aspx>) and carrying an information card about the condition in a purse or wallet can be helpful in emergencies when affected individuals may not be able to communicate their UV sensitivity.

Unshielded fluorescent lighting and bare halogen bulbs are potential UV hazards. Replacing unshielded fluorescent bulbs with light-emitting diode (LED) lights or placing plastic shielding over fluorescent bulbs can substantially reduce environmental UV exposure. Halogen lights emit substantial levels of UVB and should be avoided.

Relatively inexpensive handheld UV meters can measure UVB and UVA. Although the UVB radiation is more damaging, UVA radiation can also produce DNA damage, so protection from all wavelengths of UV is desirable. Meters can be effective learning tools; because the level of UV cannot be easily estimated, directly measuring UV in the environment provides patients and families greater ability to assess the safety of surroundings.

Vitamin D is produced in the skin by UV exposure. Rigorous sun protection may lead to low levels of vitamin D in the blood and can eventually lead to increased risk of bone fracture. *Vitamin D-rich foods* such as “fatty” fish and vitamin D supplemented milk can help maintain normal vitamin D levels; however, patients should have periodic monitoring of vitamin D levels and oral supplementation if the serum levels of 25-OH vitamin D are low.

XP patients should not use any type of tobacco product and should be protected from second-hand smoke. The benzo[a]pyrene derivatives and other carcinogens found in tobacco products and smoke induce DNA damage repaired by the NER pathway, putting the XP patient at high risk for oral and respiratory tract cancers.

The substantial *lifestyle adjustment* necessary to provide a safer UV environment can be a challenge for the family. Outdoor activities should be avoided during daylight hours, particularly between 10 AM and 2 PM. Identifying appropriate indoor play and sports activities for the affected XP child, while continuing to meet the needs of the unaffected family members, can be difficult.

The diagnosis of XP necessitates the need for *adjustment in the entire family's activities*. Outdoor events will need to be adjusted. There will be a need for increased medical services that can place significant stressors on the family and developing child. The need for frequent painful procedures (surgeries, use of topical field agents, etc.) and hospitalizations for more extensive surgeries can lead in some instances to posttraumatic stress disorder-type symptoms in some patients and families. This type of reaction occurs in patients of all ages and can result in avoidance of care. It is important to consider pain management and stress reduction appropriate for the developmental level of the XP patient when planning care. In addition, physical changes such as scarring from surgeries or progressive neurodegeneration, with the resulting disruption of normal childhood and adolescent psychosocial development, can adversely affect self-esteem. The emotional and economic stability of the family is often affected and, as with any chronic illness, the family and patient will need to go through a period of adjustment to the lifestyle changes.

Obtaining health insurance and workplace accommodations may require considerable effort. The patients may be eligible for Social Security Disability Insurance or other medical assistance. XP support groups help patients connect with other affected families and

minimize social isolation; these groups also sponsor UV-safe family activities. These include the XP Family Support Group, <http://www.xpfamilysupport.org>; the Xeroderma Pigmentosum Support Group UK, <http://xpsupportgroup.org.uk>; and the Xeroderma Pigmentosum Society, <http://www.xps.org>. There are also support groups in Germany, Japan, and the Middle East. In families with psychosocial pathologies (e.g., substance abuse or domestic violence), or if the family is having extreme difficulty coping with the diagnosis, referral to social services or a therapist may be advisable.

XP is a recessive disorder, with affecteds having two mutated alleles, and clinically normal parents (heterozygotes) carrying one mutated allele. The risk of having another affected child is 1 in 4 for each subsequent pregnancy. *Prenatal diagnosis* may be possible, and consultation with a genetic counselor can address genetic risks in future pregnancies.

For optimal management, the XP patient and family should partner with a dermatologist. Teaching patients and families to look for premalignant and malignant lesions can enable earlier identification and removal of small tumors. Depending on the rate of new tumor development, full skin examinations should be scheduled regularly (every 3–6 months). For rapidly evolving lesions more frequent visits may be necessary. Baseline whole-body photographs and close-up photos of lesions with a ruler in the image for size comparison can help track changes. Photos can be digitalized and given to the family for use at home and also kept in the medical record.

Premalignant lesions including actinic keratoses can be treated with *cryotherapy*, *topical 5-fluorouracil (5-FU)*, or *topical imiquimod*. Care needs to be taken to ensure that existing skin cancers are adequately treated. When using topical 5-FU or imiquimod as field treatments there is a risk of treating the superficial areas of skin cancer but leaving deeper areas of tumor untreated. Well-controlled studies of topical field treatments in XP patients have not been published.

Dermabrasion or *dermatome shaving* has been used to remove the superficial photodamaged epidermal layers. Theoretically, these procedures allow replacement of severely damaged epidermal cells with cells arising from the deeper, less UV-damaged adnexal structures. Newer techniques using *laser methodology for resurfacing* have also been used in a few XP patients. For patients developing many new lesions chemoprevention with *oral retinoids* (isotretinoin or acitretin) has been used. A longitudinal study of a small number of

XP patients performed at the National Institutes of Health found oral isotretinoin was effective in decreasing the number of new nonmelanoma skin cancers. However, there were many side effects in these patients, especially at the higher drug dosages. Vismodegib (Erivedge) has also been used in a few XP patients who were experiencing multiple basal cell carcinomas. There was a good response while on treatment; however, the patients experienced multiple side effects requiring discontinuing the drug for varying amounts of time.

Early and adequate *treatment of skin cancers* is extremely important. All suspected tumors should be biopsied and removed. Standard techniques, including curettage and desiccation, surgical excision, or cryosurgical ablation, can be used for small superficial lesions. Due to the extensive poikilodermatous changes and scarring in XP patients, it can be difficult to differentiate recurrent from new lesions. Mohs micrographic surgery is optimal for combining effective tumor removal with tissue sparing, which should be highly considered in the surgical plan. Several factors complicate skin cancer treatment in XP patients. Cancers may develop in a “field” of extreme actinic damage, often with little normal-appearing skin either visibly or histologically. This complicates the goal of clear margins. A more practical goal would be a tumor-free margin. In addition, the quality of actinically damaged skin in XP differs from the non-XP skin cancer patient. The non-XP cancer patient typically has damage to both epidermal cellular DNA and dermal connective tissue (collagen, elastic tissue, etc.) from high doses of UV exposure that result in lax, wrinkled skin. In contrast, damage in XP patients is caused by unrepaired epidermal cellular DNA, and the total dose of UV they have received is generally insufficient to cause typical solar elastosis, lax skin, and wrinkling. Because they develop skin atrophy, XP patients may have very tight skin, which limits tissue movement for surgical repair. In addition, movement of tissue with flaps can be complicated because of the presence of precancers or small skin cancers in the severely damaged surrounding skin. Skin cancer removal with minimal margins is also necessary to preserve tissue for future surgeries, which are to be expected in these patients.

Despite their hypersensitivity to UV, many XP patients have demonstrated a normal response to x-ray therapy when it is used to treat recurrent skin and eye cancers or brain and spinal cord neoplasms.

XP patients have a significantly increased risk for developing cancers of the lips and squamous cell carcinoma of the tip of the tongue, and these areas should be regularly evaluated. Telangiectasia on the tip of the tongue is an early UV-induced change.

Ophthalmologic care is extremely important. Most ophthalmologic problems in XP patients occur in the surface structures of the eye and may begin in childhood as photophobia and conjunctivitis.

Precancerous and cancerous lesions can arise on the cornea, sclera, lids, conjunctiva, and supporting tissues. UV damage on the cornea can lead to “dry eye,” keratitis, and conjunctival inflammation. Ectropion of the lids, resulting in defects of eye closure, can occur secondary to eyelid atrophy and surgical removal of malignancies from the periocular skin. Ectropion exacerbates eye dryness and, if left untreated, can lead to corneal ulceration, scarring and opacification of the cornea, and blindness. Corneal transplants have been performed but frequently have led to rejection from vascularization of the area. A thorough ophthalmologic examination at least yearly can include the Schirmer test for dry eye and assessment of lid closure. Eye lubricants are recommended along with lubricating ointments at night, especially if lid closure is poor.

In the United States and Europe approximately 25% of XP patients develop progressive neurologic disease. The rate of symptom progression varies greatly among patients, with the most severe patients developing symptoms in early childhood (De Santis–Cacchione syndrome). Routinely testing reflexes during skin examinations can help identify XP patients at risk for neurologic disease. Loss of deep tendon reflexes, most notably in the lower extremities, may be the first manifestation of neurodegeneration and may be the only symptom for years. Some patients may have microcephaly. Progression includes hearing loss, cognitive decline, dysarthria, dysphagia, mobility difficulties with ataxia, and falls; eventually a wheelchair may be needed. Magnetic resonance imaging (MRI) shows progressive dilation of the ventricles and loss of gray matter of the brain. Death may occur from aspiration pneumonia or other complications of severe debilitation. In a National Institutes of Health (NIH) study of 106 XP patients, the median age at death in XP patients with neurodegeneration (29 years) was significantly younger than those XP patients without neurodegeneration (37 years).

Progressive sensorineural hearing loss in XP patients may be diagnosed early, in the first decade of life, and may first be suspected

secondary to inattentiveness in school. Audiology examinations provide a sensitive method for early detection. The hearing loss can be helped with hearing aids, and assisted hearing systems may be used in the classroom.

Some XP patients appear to have an increased risk for developing internal malignancies, including an approximately 50-fold increased risk of developing primary central nervous system tumors. These may respond to full-dose x-ray therapy with normal skin reaction. However, because some XP cell lines have increased sensitivity to x-radiation, a small test dose might be advised before full-dose exposure. In addition, XP patients have been reported with myelodysplasia, acute lymphoblastic leukemia, and thyroid cancer.

With improved health care and better protective measures, XP patients are living longer, more active lives, marrying, and having children. However, some adult women with XP have developed premature menopause in their twenties and thirties. When contemplating a pregnancy, referral for preconceptual genetic counseling is recommended.

Optimal management of XP patients is a multidisciplinary process involving several medical specialties and active cooperation and input from the patient and family. With early diagnosis, rigorous UV protection, and management of skin cancers, people with XP are living well into adulthood, working in the community and raising families.

Specific Investigations

- Regular, frequent skin examination, which may include dermoscopy, to monitor for skin cancers
- Clinical photography
- High index of suspicion and low threshold for biopsy to identify possible skin cancers
- Regular ophthalmologic examinations
- Regular neurologic examinations
- Regular audiology examinations
- Regular overall history and physical examination for early detection of internal malignancy and thyroid abnormality
- UV sensitivity testing on cultured fibroblasts, if available
- DNA testing for XP gene mutations

- Exclusion of other photosensitive, pigmentary, or cancer-prone disorders (lupus, porphyria, LEOPARD syndrome, Carney complex, familial melanoma, nevoid basal cell carcinoma syndrome)

Total-body cutaneous examination, total-body photography, and dermoscopy in the care of a patient with xeroderma pigmentosum and multiple melanomas

Green WH, Wang SQ, Coggnetta AB, Jr. Arch Dermatol 2009; 145: 910–5.

Case report describing the use of regular skin examination, photography, and dermoscopy in the management of an XP patient.

Unexpected extradermatological findings in 31 patients with xeroderma pigmentosum type C

Hadj-Rabia S, Oriot D, Soufir N, Dufresne H, Bourrat E, Mallet S, et al. Br J Dermatol 2013; 168: 1109–13.

Report on the phenotypes of a group of XP-C patients in France who demonstrate neoplasms of internal organs, short stature, and thyroid nodules in addition to skin cancer.

Deep phenotyping of 89 xeroderma pigmentosum patients reveals unexpected heterogeneity dependent on the precise molecular defect

Strict sun protection results in minimal skin changes in a patient with xeroderma pigmentosum and a novel c.2009delG mutation in XPD (ERCC2)

Emmert S, Ueda T, Zumsteg U, Weber P, Khan SG, Oh KS, et al. Exp Dermatol 2009; 18: 64–8.

A case report describing strict UV protection in an XP child with neurologic degeneration. The UV protection did not affect the neurodegeneration; however, there were only very mild skin manifestations and no skin cancer.

Second-Line Therapies

• Topical imiquimod	B
• Topical 5-fluorouracil	B
• Oral retinoid therapy	C

Therapeutic response of a brother and sister with xeroderma pigmentosum to imiquimod 5% cream

Weisberg NK, Varghese M. *Dermatol Surg* 2002; 28: 518–23.

Siblings diagnosed with XP failed chemoprophylaxis for dozens of tumors with oral retinoids. Treatment with imiquimod 5% cream was initiated three times per week for several months. Both patients experienced reduction of new tumor development and resolution of multiple existing basal cell carcinomas. One sibling demonstrated a robust inflammatory response, and the other had little visible reaction.

5% 5-fluorouracil cream for the treatment of small superficial basal cell carcinoma: efficacy, tolerability, cosmetic outcome, and patient satisfaction

Gross K, Kircik L, Kricorian G. *Dermatol Surg* 2007; 33: 433–9.

Evaluated the efficacy, tolerability, cosmetic outcome, and patient satisfaction of 5% FU treatment for superficial basal cell carcinomas in 29 patients. Histologic cure rate was 90%, and patients were generally very satisfied with the treatment. These were not XP patients.

Prevention of skin cancer in xeroderma pigmentosum with the use of oral isotretinoin

Kraemer KH, DiGiovanna JJ, Moshell AN, Tarone RE, Peck GL. *N Engl J Med* 1988; 318: 1633–7.

Five XP patients were treated for a total of 2 years with high-dose (2 mg/kg/day) isotretinoin. The patients had a total of 121 tumors before

treatment, and only 25 tumors occurred during treatment. The tumor frequency increased 8.5-fold after the drug was discontinued. However, there were significant side effects on the drug, including cutaneous, triglyceride, liver function, or skeletal problems.

Xeroderma pigmentosum: spinal cord astrocytoma with 9-year survival after radiation and isotretinoin therapy

DiGiovanna JJ, Patronas N, Katz D, Abangan D, Kraemer KH. J Cutan Med Surg 1998; 2: 153–8.

Case report of an XP patient who received radiation therapy for a spinal cord astrocytoma with normal cutaneous response to standard dosages.

Topical imiquimod or fluorouracil therapy for basal and squamous cell carcinoma: a systematic review

Love WE, Bernhard JD, Bordeaux JS. Arch Dermatol 2009; 145: 1431–8.

A systematic review of topical imiquimod or FU therapy in the treatment of basal cell and squamous cell carcinomas in the general population.

Topical imiquimod or fluorouracil therapy for basal and squamous cell carcinoma: a systematic review

Love WE, Bernhard JD, Bordeaux JS. Arch Dermatol 2009; 145: 1431–8.

A case report of an XP patient who had multiple skin grafts and experienced tumor recurrence, which originated under the skin graft.

Third-Line Therapy

• Resurfacing and dermabrasion and chemical peels	E
---	----------

The role of dermabrasion and chemical peels in the treatment of patients with xeroderma pigmentosum

Nelson BR, Fader DJ, Gillard M, Baker SR, Johnson TM. J Am Acad Dermatol 1995; 32: 623–6.

A case report of two XP patients treated periodically with

trichloroacetic acid chemical peels; one also underwent dermabrasion. Both procedures provided some prophylactic effects, with the dermabrasion having better results. Before and after pictures are presented.

Xerosis

Ian Coulson

Xerosis is the term used to describe a condition where there is a rough, dry textural feel to the skin, accompanied by fine scaling and sometimes fine fissuring. Increasing xerosis is usually accompanied by increasing itch. It may result from a combination of environmental conditions (low humidity, degreasing of the skin by excessive bathing, soap, or detergent use); genetic disorders of keratinization (ichthyoses); atopic eczema (where it may be a manifestation of a filaggrin mutation); endocrine disease states (hypothyroidism);

diabetes mellitus (39% of patients); and a host of underlying disease states such as chronic renal failure, liver disease (including 69% of patients with primary biliary cirrhosis), malnutrition, anorexia nervosa (58% of patients), essential fatty acid deficiency, Sjögren syndrome (56% of patients), HIV infection, lymphoma (where it may result in an acquired ichthyosis), and carcinomatosis (especially hematologic). It is more common in the elderly. Drugs (statins and targeted chemotherapeutic agents such as EGFR and BRAF inhibitors) are occasionally implicated. It is reported to be more frequent in the winter.

Management Strategy

Initial evaluation should seek to distinguish simple xerosis from a genetic ichthyosis, although management is similar for both conditions. Family history, distribution, and morphology will help to differentiate the two. A history of weight loss, diarrhea, dietary history, and body mass index may give clues toward an underlying metabolic or malabsorptive disorder. Dry eyes and mouth may indicate underlying Sjögren syndrome. History and clinical examination should seek symptoms and signs of hypothyroidism, diabetes mellitus, and chronic renal disease. Drug use and sexual contact history may reveal HIV infection. Xerosis is an almost universal accompaniment of atopic eczema.

The mainstay of therapy for xerosis after any underlying disorders (if possible) are corrected is *improvement of the humidity* in the patient's environment, *avoidance of exacerbating factors* such as soap and detergents, and the use of *emollients or humectants*.

Low environmental humidity both at home and work will exacerbate xerosis of any cause. Arid air is a problem in air-conditioned homes, offices, and vehicles. Hot dry air directed to the lower legs during the winter in the front of automobiles is a common cause of lower leg xerosis. In the home or workplace humidifiers can be fitted over radiators; alternatively, placing wet towels or containers of water over them will increase air humidity.

Soaps and detergents degrease the skin, reduce epidermal thickness, and increase scale and itch, and so are best avoided, and light emollient cleansers (soap substitutes) are suggested in their place. Bathing in tepid water is often preferred by patients, and patting the skin dry will produce less scale and dryness than vigorous

towelings.

Emollients (which simply produce an impervious film over the epidermis and prevent “transpiration”) and humectants (such as lactic acid, urea, or glycerine that hold water in the epidermis osmotically) are the mainstays of therapy. Few good comparative studies exist for the most common type of xerosis, which is surprising because they are the most frequently used dermatologic products. They should be used liberally and as frequently as possible and applied in the direction of hair growth; emollients are particularly valuable after bathing or showering to hold water in the epidermis. Light emollients for use in the shower or bath may be preferred to *bath oils* by some. Choice of emollient is entirely personal to the patient. A pack with small amounts of a variety of products for home trial or a self-selection “tub tray” for the clinic is likely to enhance compliance. The best emollient is the one the patient likes; the most expensive is the one where 499 g remains in the tub!

Agents containing *α-hydroxy acids (AHAs)* may offer some advantages over conventional paraffin-based emollients, but this may be at the expense of irritation in some people. Low-concentration *salicylic acid* may help reduce scale in more severe xerosis, but it is essential to remember that systemic absorption and salicylism can occur.

Topical retinoids have only been used in the more severe ichthyoses and are too irritating for use in xerosis. Systemic therapies have little part to play in most patients.

Specific Investigations

- Thyroid function tests
- Renal function tests
- Random glucose
- Consider tests for Sjögren syndrome, HIV infection, malignancies, and malabsorption, if clinically indicated
- Drug history

Sjogren’s syndrome: a retrospective review of the cutaneous features of 93 patients by the Italian Group of Immunodermatology

Bernacchi E, Amato L, Parodi A, Cottoni F, Rubegni P, De Pità O, et

al. Clin Exp Rheumatol 2004; 22: 55–62.

Over half of 93 patients with Sjögren syndrome had xerosis, and its presence correlated with the presence of SSA and SSB antibodies.

HIV-associated pruritus: etiology and management

Singh F, Rudikoff D. Am J Clin Dermatol 2003; 4: 177–88.

Xerosis is one of the more common causes of itch in HIV infection and AIDS.

Noninfectious skin conditions associated with diabetes mellitus: a prospective study of 308 cases

Diris N, Colomb M, Leymarie F, Durlach V, Caron J, Bernard P. Ann Dermatol Venereol 2003; 130: 1009–14.

Xerosis was noted in 39% of 309 patients.

Eating disorders and the skin

Strumia R. Clin Dermatol 2013; 31: 80–5.

Xerosis is a common feature of anorexia.

Xerosis from lithium carbonate

Hoxtell E, Dahl MV. Arch Dermatol 1975; 111: 1073–4.

Incidence and risk of xerosis with targeted anticancer therapies

Valentine J, Belum VR, Duran J, Ciccolini K, Schindler K, Wu S, et al. J Am Acad Dermatol 2015; 72: 656–72.

About 20% of patients receiving targeted therapies develop significant xerosis.

Litt's Drug Eruption Reference and Database lists in excess of 150 drugs (from acebutolol to zonisamide) that have been implicated in causing xerosis. Retinoids, cimetidine, protease inhibitors, statins, and nicotinamide are perhaps the best known. Epidermal growth factors and targeted chemotherapy agents are new agents that have xerosis among their protean dermatologic side effects.

First-Line Therapies

• Soap avoidance	A
• Humidification	C
• Emollients	B
• Bath oils	B

Moisturizers are effective in the treatment of xerosis irrespectively from their particular formulation: results from a prospective, randomized, double-blind controlled trial

Shim JH, Park JH, Lee J, Lee DY, Lee JH, Yang JM. J Eur Acad Dermatol Venereol 2016; 30: 276–81.

A double-blind trial evaluating the effect of four conventional popular emollients, as well as a new cream containing recombinant epidermal growth factor and its control vehicle. All of the evaluated agents improved the clinical symptoms of xerosis. Consistent and regular moisturization was more important than the emollients' particular formulation. This reinforces the dogma that the best emollient is the one the patient likes and uses.

Emollients improve treatment results with topical corticosteroids in childhood atopic dermatitis: a randomized comparative study

Szczepanowska J, Reich A, Szepietowski JC. Pediatr Allergy Immunol 2008; 19: 614–8.

In a study of 52 children with atopic dermatitis, those applying emollients concurrently with topical corticosteroids had significantly improved xerosis.

How useful are soap substitutes?

Berth-Jones J, Graham-Brown RAC. J Dermatol Treat 1992; 3: 9–11.

Thirty-eight subjects with atopic dermatitis, psoriasis, or senile xerosis were treated with emulsifying ointment BP or Wash E45 as soap substitutes. Dryness and itching improved in both groups. Wash E45 was considered more effective as a cleanser.

The value of oil baths for adjuvant basic therapy of inflammatory dermatoses with dry, barrier-disrupted skin

Melnik B, Braun-Falco O. Hautarzt 1996; 47: 665–72.

The use of oil baths with emollients is an integral and indispensable constituent of maintenance therapy in dry skin conditions, atopic eczema, and inflammatory dermatoses.

Second-Line Therapies

• Urea-containing creams	A
• Lactic acid–containing creams	A
• Ammonium lactate creams	A
• Colloidal oatmeal	A
• AHA creams	B
• Thyroxine cream	D
• Glycerol containing creams	B
• Chia oil	D

A double blind comparison of two creams containing urea as the active ingredient. Assessment of efficacy and side effects by noninvasive techniques and a clinical scoring scheme

Serup J. Acta Derm Venereol 1992; 177: 34–43.

A comparison of 3% and 10% urea cream showed that both were effective at reducing scale, dryness, and laboratory parameters (transepidermal water loss and colorimetric changes). The 10% cream was better at restoring the skin's water barrier function.

Clinical evaluation of 40% urea and 12% ammonium lactate in the treatment of xerosis

Ademola J, Frazier C, Kim SJ, Theaux C, Saudez X. Am J Clin Dermatol 2002; 3: 217–22.

A double-blind study comparing 40% urea cream with 12% ammonium lactate cream showing superiority of the urea cream. Flexural irritation was a problem.

Many urea-containing products contain lower concentrations than used in this study.

Use of a urea, arginine and carnosine cream versus a standard emollient glycerol cream for treatment of severe xerosis of the feet in patients with type 2 diabetes: a randomized, 8 month, assessor-blinded, controlled trial

Federici A, Federici G, Milani M. Curr Med Res Opin 2015; 31: 1063–9.

Fifty diabetics with severe foot xerosis fared better with the combination cream in comparison to a simple glycerine-containing emollient.

A controlled two-center study of lactate 12% lotion and a petrolatum-based creme in patients with xerosis

Wehr R, Krochmal L, Bagatell F, Ragsdale W. Cutis 1986; 37: 205–7.

Lactate lotion 12% was significantly more effective than a petrolatum-based cream in reducing the severity of xerosis during treatment and posttreatment phases.

Comparative efficacy of 12% ammonium lactate lotion and 5% lactic acid lotion in the treatment of moderate to severe xerosis

Rogers RS III, Callen J, Wehr R, Krochmal L. J Am Acad Dermatol 1989; 21: 714–6.

This comparative study of twice-daily application of 5% lactic acid vs. 12% ammonium lactate lotion showed superiority of 12% ammonium lactate in reducing the severity of xerosis.

A double-blind clinical trial comparing the efficacy and safety of

pure lanolin versus ammonium lactate 12% cream for the treatment of moderate to severe foot xerosis

Jennings MB, Alfieri DM, Parker ER, Jackman L, Goodwin S, Lesczczynski C. *Cutis* 2003; 71: 78–82.

A study showing equivalence of a petrolatum compound and 12% ammonium lactate cream for foot xerosis.

A randomized controlled clinical study to evaluate the effectiveness of an active moisturizing lotion with colloidal oatmeal skin protectant versus its vehicle for the relief of xerosis

Kalaaji AN, Wallo W. *J Drugs Dermatol* 2014; 13: 1265–8.

A randomized, double-blind, controlled clinical study to objectively compare a commercially available moisturizing product against its own vehicle. The active colloidal oatmeal moisturizer used in this study showed significant benefits versus its vehicle control in several dermatologic parameters used to measure skin dryness.

An evaluation of the effect of an alpha hydroxy acid-blend skin cream in the cosmetic improvement of symptoms of moderate to severe xerosis, epidermolytic hyperkeratosis, and ichthyosis

Kempers S, Katz HI, Wildnauer R, Green B. *Cutis* 1998; 61: 347–50.

Twenty subjects completed a course of treatment with either regular or extra-strength AHA-blend cream on a test site compared with a currently marketed, non-AHA moisturizing lotion on a control site. Improvements were significant compared with baseline and compared with sites treated with the control lotion, but the AHA cream did cause some local mild to moderate adverse effects; all subjects were able to continue using the test product for the duration of the study.

Randomized, double-blind study with glycerol and paraffin in uremic xerosis

Balaskas E, Szepietowski JC, Bessis D, Ioannides D, Ponticelli C, Ghienne C, et al. *Clin J Am Soc Nephrol* 2011; 6: 748–52.

An emollient containing glycerol and paraffin compared side to side with an emulsion devoid of these agents. The active treatment helped reduce the physical signs of xerosis as well as the pruritus.

Effectiveness of topical chia seed oil on pruritus of end-stage renal disease (ESRD) patients and healthy volunteers

Jeong SK, Park HJ, Park BD, Kim IH. Ann Dermatol 2010; 22: 143–8.

A small study demonstrating effectiveness using this *n*-3 fatty acid-containing oil in normal people and renal failure sufferers with xerosis.

Yellow nail syndrome

Robert Baran

The yellow nail syndrome (YNS) is an uncommon disorder of unknown etiology characterized by the triad of yellow nails, lymphedema, and respiratory tract involvement. This term was originally used to describe the association of slow-growing yellow nails with primary lymphedema. Pleural effusion was later recognized to be an additional sign of the syndrome. Since then, other respiratory conditions, such as bronchiectasis, sinusitis, bronchitis, and chronic respiratory infections, have been associated with the disorder. Although all three signs that classically characterize the

triad of YNS do not occur in every patient, the presence of typical nail alterations should be considered an absolute requirement for the diagnosis. The complete triad is seen in 25% of patients, lymphedema in 40%, and pleural effusions in only 2% of patients with yellow nails. A variant of yellow nails can also be seen in HIV infection.

Management Strategy

Although YNS may resolve spontaneously, treatment is often sought by sufferers. The nails are unsightly, discolored (yellowish or greenish), hard, show transverse overcurvature with a hump, and are very slow growing. Paronychia and onycholysis can be observed.

Underlying diseases such as respiratory disorders, malignancy (Table 259.1), infections, immunologic and hematologic abnormalities, endocrine, connective tissue, renal abnormalities, and miscellaneous disorders, including drug-induced YNS, *dental amalgams*, and *titanium exposure* (Box 259.1), should be sought. Improvement of any underlying disorder (e.g., lymphedema) may also result in improvement of the nail plate.

There are no large series or randomized trials in the treatment of yellow nail syndrome. *Oral vitamin E* has been used as monotherapy. The oral azole antifungals *itraconazole* and *fluconazole* have also been reported to be effective, alone or in combination with vitamin E. *The combination of fluconazole and vitamin E is certainly the best treatment for curing the nail unit.* This was confirmed by some anecdotal reports that supplement our own statistics. Repeated *nail matrix steroid injections* have been successfully employed. *Octreotide*, *zinc*, and *medium-chain fatty acid triglyceride supplements* as well as *clarithromycin* have been used in anecdotal reports. *Treatment of underlying disease (or concomitant disorder) is mandatory but does not always bring resolution of the YNS, and cure of the nail is not always accompanied by disappearance of the other signs.*

Table 259.1

Systemic causes possibly associated with yellow nail syndrome

Adenocarcinoma of the endometrium	Drugs: bucillamine, penicillamine, thiol, gold
Anaplastic undifferentiated tumor	Hodgkin disease
Arteriovenous fistula	Laryngeal carcinoma
Autoimmune hypothyroidism	Membranous glomerulonephritis
Breast carcinoma	Metastatic malignant melanoma

(After Gupta AK. Cutis 1986; 37: 371–4 and Lotfolollah L, et al. Tanaffos 2015; 14: 57–1.)

Specific Investigations

- Rule out fungal or *Pseudomonas* infection
- Serum rheumatoid factors
- Complete blood count
- Chemistry profile with blood creatinine
- Urinalysis, proteinuria
- Sinus and chest radiography
- Immunoelectrophoresis
- Ear/nose/throat (ENT) and pulmonary investigations
- Thyroid-stimulating hormone (TSH)
- Liver enzymes, alkaline phosphatases
- Cone beam computed tomography (CBCT)
- Search for titanium dioxide in the nail

Box 259.1 Exposure to Titanium Dioxide

- Foods such as candy, chewing gum, and chocolate
- Personal care items, such as shampoo, sunscreen, and toothpaste
- Drugs such as multivitamins

(Modified from Decker A, et al. Skin Appendage Disord 2015; 1: 28–30.)

First-Line Therapies

• α -Tocopherol + fluconazole	B
• Treatment of the concomitant disorder	E

Combination of fluconazole and α -tocopherol in the treatment of yellow-nail syndrome

Baran R, Thomas L. J Drugs Dermatol 2009; 8: 276–8.

Daily treatment with 500 mg oral vitamin E morning and evening associated with weekly 300 mg fluconazole should be taken as long as needed.

Usually complete cure has been obtained in 18 to 24 months. However, there is still a wide discrepancy between the response of the nail to treatment and the remaining signs, which are usually unimproved.

T and B cell deficiency associated with yellow nail syndrome

Gupta S, Samra D, Yel L, Agrawal S. Scand J Immunol 2012; 75: 329–35.

Immunoglobulin administration resulted in the decreased frequency and severity of infections, and an impressive effect was observed on lymphedema and on the recurrence of pleural effusion.

Second-Line Therapies

• Intradermal triamcinolone injections in the proximal nail matrix	B
• Clarithromycin	E
• Physiotherapy	E

Yellow nail syndrome treated by intralesional triamcinolone acetate

Abell E, Samman PD. Br J Dermatol 1973; 88: 200–1.

Repeated intradermal triamcinolone injections in the proximal nail matrix might be effective on the nail unit, but they are no longer in use.

A case of yellow nail syndrome with dramatically improved nail discoloration by oral clarithromycin

Suzuki M, Yoshizawa A, Sugiyama H, Ichimura Y, Morita A, Takasaki J, et al. Case Rep Dermatol 2011; 3: 251–8.

Dramatic improvement of the yellow nail discoloration and growth of nails in one patient treated daily with 400 mg clarithromycin.

Syndrôme des ongles jaunes d'évolution favorable: rôle de la kinésithérapie respiratoire?

Fournier C, Just N, Leroy S, Wallaert B. Rev Mal Resp 2003; 20: 969–72.

Besides the nail manifestations, the patient had bilateral bronchiectasis. Daily physiotherapy with bronchial drainage led to a progressive improvement in the respiratory signs. The nail abnormalities disappeared after 2 years of treatment.

Improvement in lymphatic function and partial resolution of nails, after complete decongestive physiotherapy in yellow nail syndrome

Szolnoky G, Lakatos B, Husz S, Dobozy A. Int J Dermatol 2005; 44: 501–3.

Manual lymphatic drainage was performed on each leg for 45 minutes, and multilayered compression bandaging was subsequently applied. This was repeated daily for 2 weeks, except at weekends, when the compression was not accompanied by massage. The edema reduction and the increase in lymph flow were associated with an improvement in the appearance of the toenail plates. Fingernails failed to show any change.

Third-Line Therapies

• Oral zinc supplementation	E
• Dietary treatment	E
• Octreotide treatment	E

Improvement of yellow nail syndrome with oral zinc supplementation

Arroyo JF, Cohen ML. Clin Exp Dermatol 1993; 18: 62–4.

Total resolution of yellow nails and lymphedema was observed after oral zinc supplementation for 2 years.

Yellow nail syndrome in a 10-year-old girl

Göçmen A, Küçükosmanoğlu O, Kiper N, Karaduman A, Özçelik U. J Pediatr 1997; 39: 105–9.

Low-fat diet supplemented with medium-chain triglycerides brought moderate improvement in the lymphedema of the lower extremities.

Successful octreotide treatment of chylous pleural effusion and lymphedema in the yellow nail syndrome

Makrilakis K, Pavlatos S, Giannikopoulos G, Toubanakis C, Katsilambros N. Ann Intern Med 2004; 141: 246–7.

Octreotide, a somatostatin analog, was effective in a classic case of YNS with yellow nails, lymphedema of lower extremities, and recurrent chylous pleural effusion.

Yellow nail syndrome: report of a case successfully treated with octreotide

Lotfollahi L, Abedini A, Alavi Darazam I, Kiani A, Fadaei A. Tanaffos 2015; 14: 67–71.

Angiotensin-converting enzyme (ACE) inhibitors, for scleroderma, [765](#)

Angular cheilitis, [44–45](#), [44f](#)

Anifrolumab, for systemic lupus erythematosus, [801](#)

Anogenital warts, [288](#), [288f](#)

Anorexia

chilblains with, [145](#)

prurigo pigmentosa associated with, [676](#)

xerosis in, [879](#)

Antacid, for aphthous stomatitis, [51](#)

Anthralin

for alopecia areata, [29–30](#), [33](#)

for granuloma annulare, [306](#)

- for inflammatory linear verrucous epidermal nevus, [222–223](#)
- for nail psoriasis, [547](#)
- for psoriasis, [697](#), [699](#)
- for warts, [857–858](#)

Anthralin-induced dermatitis, in alopecia areata, [30](#)

Anthrax, [96](#)

Anthrax Vaccine Adsorbed (AVA), for anthrax, [98](#)

Anti-androgens

- for acne vulgaris, [8](#)
- for androgenetic alopecia, [39](#)
- for extramammary Paget disease, [267](#)
- for hirsutism, [361](#)

Anti-anxiolytics, for psychogenic excoriation, [708](#)

Anti-CD20 antibody, *See* [Rituximab](#)

Anti-CD52 antibody, *See* [Alemtuzumab](#)

Anti-immunoglobulin E treatment

- for aquagenic pruritus, [373](#)
- for cutaneous mastocytosis, [492](#)

See also [Omalizumab](#)

Anti-interferon alpha receptor monoclonal antibody, for systemic lupus erythematosus, [801](#)

Anti-Mi-2 antibodies, for dermatomyositis, [199](#)

Anti-Scl-70 antibodies, for scleroderma, [765](#)

Anti-tumor necrosis factor (TNF) agents

- for adult-onset pityriasis rubra pilaris, [253](#)
- for Behçet disease, [90](#)
- for dermatomyositis, [201–202](#)
- for febrile ulceronecrotic Mucha-Habermann disease, [637](#)
- for fish tank granuloma, [527](#)

histoplasmosis complicating, [348](#)
for mucous membrane pemphigoid, [520](#)
for palmoplantar pustulosis, [583](#)
for pityriasis lichenoides et varioliformis acuta, [637](#)
for psoriasis, [698](#)
 pustular, [706](#)
for reactive arthritis, [726](#), [729](#)
for relapsing polychondritis, [735](#)
subacute cutaneous lupus erythematosus induced by, [797](#)
for subcorneal pustular dermatosis, [802–803](#)

See also [Adalimumab](#), [Etanercept](#), [Infliximab](#)

Antiaminoacyl-tRNA synthetase autoantibodies, dermatomyositis, [199](#)

Antibiotics

for acne keloidalis nuchae, [4](#)
for acne vulgaris, [6](#)
for acute generalized exanthematous pustulosis, [24](#)
for anthrax, [97–98](#)
for atopic dermatitis, [56](#)
for bacillary angiomatosis, [10021#s0115](#), [74](#)
for blistering distal dactylitis, [108](#)
for cat scratch disease, [134](#)
for cellulitis, [141](#)
for comedonal acne, [641](#)
for decubitus ulcers, [182](#)
for discoid eczema, [206](#)
for dissecting cellulitis of scalp, [211](#)
for epidermolysis bullosa, [226](#)
for erysipelas, [141](#)

for erythrasma, [248](#)
for folliculitis, [278](#)
for folliculitis decalvans, [281](#)
for furunculosis, [286](#)
for granuloma inguinale, [309](#)
for impetigo, [369–370](#)
for lichen sclerosus, [447](#)
for Lyme borreliosis, [466](#)
for lymphedema, [470](#)
for lymphocytoma cutis, [472](#)
for miliaria, [505](#)
for molluscum contagiosum, [508](#)
for MRSA, [286](#), [499](#), [501–502](#)
for papular urticaria, [590](#)
for paronychia, [602](#)
for pitted and ringed keratolysis, [626](#)
for pityriasis lichenoides chronica, [632](#)
for plague, [100](#)
for pseudofolliculitis barbae, [691](#)
for psoriasis, [704](#)
for psychogenic excoriation, [708](#)
for reactive arthritis, [726](#), [729](#)
for rickettsial spotted fevers, [739](#)
for rosacea, [744](#), [750](#)
for rosacea fulminans, [751](#)
for scleredema, [761](#)
for staphylococcal scalded skin syndrome, [785](#)
for Stevens-Johnson syndrome, [831–833](#)

See also [Antimicrobials](#)

Antibodies, for Merkel cell carcinoma, [496–497](#)

Anticandidal preparations, for paronychia, [600](#)

Anticardiolipin antibodies

in livedo reticularis, [458](#)

in livedoid vasculopathy, [461](#)

Anticholinergic drugs

effects of, [354](#)

for hyperhidrosis, [354](#)

Anticoagulants

for livedoid vasculopathy, [461](#)

for malignant atrophic papulosis, [481](#)

Anticonvulsants, for notalgia paresthetica, [569](#)

Antidepressants

for dermatitis artefacta, [190](#)

for erythromelalgia, [258](#)

for psychogenic excoriation, [708](#)

Antiestrogen

for autoimmune progesterone dermatitis, [70](#)

for dermatomyositis, [202](#)

for hereditary hemorrhagic telangiectasia, [332](#)

Antifungals

for candidiasis, cutaneous, [171](#)

for chromoblastomycosis, [151–153](#)

for cryptococcosis, [169](#)

for diaper dermatitis, [203](#)

for onychomycosis, [825](#)

for palmoplantar keratoderma, [579](#)

- for paracoccidioidomycosis, [593](#)
- for paronychia, [601](#)
- for pitted and ringed keratolysis, [626](#)
- for pityriasis versicolor, [827](#)
- for seborrheic eczema, [772–773](#)
- for skin dermatophytosis, [821](#)
- subacute cutaneous lupus erythematosus induced by, [797](#)
- for tinea capitis, [816–818](#)
- for tinea pedis, [820](#)

Antihistamines

- for amyloidosis, [34](#)
- for angioedema, [843](#)
- for aquagenic pruritus, [376](#)
- for atopic dermatitis, [55](#), [60](#)
- for atopic eruption of pregnancy, [667](#)
- for discoid eczema, [206](#)
- for drug eruptions, [214](#)
- for erythropoietic protoporphyria, [261](#)
- for Gianotti-Crosti syndrome, [293](#)
- for Grover disease, [835](#)
- for intrahepatic cholestasis of pregnancy, [665–666](#)
- for lichen planus, [441](#)
- for lichen simplex chronicus, [448](#)
- nonsedating, [373t](#)
- for papular urticaria, [590](#)
- for pemphigoid gestationis, [663](#)
- for pityriasis lichenoides et varioliformis acuta, [635](#)
- for pompholyx, [319](#)

- for prurigo nodularis, [672](#)
 - for pruritus ani, [686](#)
 - for pruritus vulvae, [688](#)
 - for psychogenic excoriation, [708](#)
 - sedating, [373t](#)
 - for urticaria, [841](#), [841t](#)
 - for Wells syndrome, [869](#)
- Antihypertensive agents, subacute cutaneous lupus erythematosus induced by, [797](#)
- Antiinfective agents, *See* [Antibiotics](#), [Antifungals](#), [Antimicrobials](#)
- Antiinflammatory agents
- for epidermolysis bullosa acquisita, [229](#)
 - for necrobiosis lipoidica, [548](#)
 - for neurofibromatosis type 1, [559](#)
 - for seborrheic eczema, [773–774](#)
- See also* [Nonsteroidal antiinflammatory drugs](#)
- Antiinterleukin-1 receptor antagonist anakinra, for Sweet syndrome, [808](#)
- Antimalarials
- for dermatomyositis, [200](#)
 - for discoid lupus erythematosus, [209–210](#)
 - for erythema multiforme, [244](#)
 - for granuloma annulare, [305](#)
 - for Jessner lymphocytic infiltrate, [384](#)
 - for lupus panniculitis, [584](#), [586](#)
 - for lymphocytoma cutis, [472](#)
 - for subacute cutaneous lupus erythematosus, [797–798](#)
 - smoking and, [797](#)
 - for Wells syndrome, [868](#)

Antimicrobial mouth rinse, for aphthous stomatitis, [50](#)

Antimicrobials

for decubitus ulcer, [185](#)

for lichen planus, [443](#)

for *Mycobacterium ulcerans* infection, [528](#)

See also [Antibiotics](#), [Antifungals](#), [Antivirals](#)

Antinuclear antibodies (ANAs)

for discoid lupus erythematosus, [209](#)

for polymorphic light eruption, [643–644](#)

Antioxidants

for erythropoietic protoporphyria, [262](#)

for polymorphic light eruption, [645](#)

Antiphospholipid syndrome, [46–48](#), [46f](#)

Antiplatelet therapy, for necrobiosis lipoidica, [549](#)

Antipruritics

for Grover disease, [834](#)

for perforating dermatoses, [616](#)

for pityriasis rubra pilaris, [629](#)

Antipsychotics

for delusional parasitosis, [188–189](#)

for psychogenic excoriation, [708](#)

Antiretroviral therapy

for histoplasmosis, [347](#)

for HIV-associated pityriasis rubra pilaris, [631](#)

for Kaposi sarcoma, [391](#)

paronychia associated with, [601](#)

for pompholyx, [319–321](#)

for porphyria cutanea tarda, [652](#)

for reactive arthritis, [728](#)

Antiseptics

for atopic dermatitis, [56](#)

for impetigo, [371](#)

for molluscum contagiosum, [508](#)

Antithrombotics

for antiphospholipid syndrome, [47](#)

for Kawasaki disease, [397](#)

for Sneddon syndrome, [457](#)

α_1 -Antitrypsin deficiency panniculitis, [585](#), [589](#)

Antituberculous therapy

for erythema induratum of Bazin, [587](#)

for lichen nitidus, [437](#)

for *Mycobacterium kansasii* infection, [529](#)

Antivenoms, for jellyfish stings, [383](#)

Antivirals

for herpes genitalis, [334–335](#)

for herpes labialis, [337](#)

for hydroa vacciniforme, [352](#)

for pityriasis rosea, [639](#)

for postherpetic neuralgia, [341](#)

Anxiolytic medications, for dermatitis artefacta, [191](#)

Aortic regurgitation, in relapsing polychondritis, [736](#)

Aortic valve inflammation, in relapsing polychondritis, [733](#)

Aphthous stomatitis, [49–53](#), [49f](#)

Apligraf, for epidermolysis bullosa, [227](#)

Apocrine gland, Fox-Fordyce disease and, [284](#)

Apremilast

- for Behçet disease, [93](#)
- for nail psoriasis, [545](#)
- for psoriasis, [702](#)
- for sarcoidosis, [752](#), [755](#)

Aquagenic pruritus, [376](#), [684–685](#)

Arginine, for xerosis, [879](#)

L-arginine, for Raynaud's phenomenon, [724–725](#)

Argon laser

- for granuloma faciale, [308](#)
- for lymphocytoma cutis, [474](#)
- for Peutz-Jeghers syndrome, [621](#), [623](#)
- for pyogenic granuloma, [716–717](#)
- for rhinophyma, [737](#)
- for sebaceous hyperplasia, [770](#)
- for verrucous epidermal nevus, [221–222](#)
- for xanthomas, [871](#)

Argon plasma coagulation, for hereditary hemorrhagic telangiectasia, [331](#)

Aripiprazole

- for delusional parasitosis, [189](#)
- for dermatitis artefacta, [191](#)
- for psychogenic excoriation, [708](#), [710](#)

Aromatherapy, for alopecia areata, [33](#)

Aromatic diamidine, for leishmaniasis, [418](#)

Arotinoid ethylester, for erythrokeratoderma variabilis, [257](#)

Arterial ulcers, [414](#)

Arthropathy, in human parvovirus B19 infection, [603](#)

Artificial dermis, for warts, [856](#)

Artificial tears, for ocular rosacea, [750](#)

Ascorbic acid

- for aphthous stomatitis, [52](#)
- for capillaritis, [132](#)
- for complex regional pain syndrome, [731–732](#)
- for decubitus ulcers, [182](#)
- for erythropoietic protoporphyria, [262](#)
- for miliaria and hypohidrosis, [507](#)
- for porphyria cutanea tarda, [652](#)
- for striae, [796](#)

Ashy dermatosis, [659](#)

Asphyxiation therapy, for myiasis, [10162#s0085](#)

Aspiration biopsy, for subcutaneous fat necrosis of newborn, [805](#)

Aspirin

- alcohol-induced flushing, [273](#)
- for antiphospholipid syndrome, [47](#)
- for erythromelalgia, [259](#)
- for Fabry disease, [268](#)
- for herpes genitalis, [335](#)
- for Kawasaki disease, [395](#)
- for lichen simplex chronicus, [448](#)
- for livedoid vasculopathy, [461](#)
- for malignant atrophic papulosis, [482](#)
- for necrobiosis lipoidica, [548](#)
- nicotinic acid-induced flushing, [273](#)
- for Raynaud's phenomenon, [724](#)
- for Sneddon syndrome, [458](#)

Astemizole, for lichen nitidus, [436](#)

Astringent, for paronychia, [600](#)

Asymmetric periflexural exanthema (unilateral lateral thoracic syndrome), [603](#)

AT1001, for Fabry disease, [271](#)

Atopic dermatitis, [54–62](#), [54f](#)

- in adult, [59](#)
- in children, [58](#), [60](#)
- discoid eczema and, [206](#)
- Gianotti-Crosti syndrome and, [294](#)
- miliaria and, [505–506](#)

Atopic eruption of pregnancy, [666–667](#)

“Atopic winter feet” ((juvenile plantar dermatosis), [386](#)

Atopy

- in juvenile plantar dermatosis, [386](#)
- in perioral dermatitis, [619](#)

Atrophic parapsoriasis, *See* [Large plaque parapsoriasis](#)

Atrophie blanche, [461](#)

Atrophoderma vermiculatum, [407](#)

Atropine, for syringomas, [815](#)

Atypical fibroxanthoma (AFX), [63–65](#), [63f](#)

Atypical keratosis pilaris, practical management of, [407](#)

Atypical nevi, [66–69](#), [66f](#)

Auranofin

- for Jessner lymphocytic infiltrate, [385](#)
- for nodular vasculitis, [587](#)

Auricular acupuncture, for warts, [858](#)

Auricular chondritis, [733](#)

Auricular pressure-relieving device, for chondrodermatitis nodularis helcis chronicus, [148](#)

Australian lemon myrtle (*Backhousia citriodora*), for molluscum

contagiosum, [510](#)

Autoantibodies

for dermatomyositis, [199](#)

for epidermolysis bullosa acquisita, [229](#)

for pemphigoid gestationis, [663](#)

Autoimmune blistering disease, antiphospholipid antibodies with, [117](#)

Autoimmune connective tissue disease, with calcinosis cutis, [125](#)

Autoimmune diseases, vitiligo and, [860](#)

Autoimmune progesterone dermatitis, [70–72](#), [70f](#), [235](#)

Autoimmunity, pretibial myxedema with, [669](#)

Autologous blood, for Raynaud's syndrome, [725](#)

Autologous hematopoietic stem cell transplantation (AHSCT), for diffuse cutaneous systemic sclerosis, [767](#)

Autologous transplantation, for vitiligo, [862](#)

Autosomal recessive congenital ichthyosis, [366](#)

Avelumab, for Merkel cell carcinoma, [498](#)

Aversion therapy, for psychogenic excoriation, [710](#)

Axillary hyperhidrosis, [355](#)

Azacytidine, for Sweet syndrome, [809](#)

Azathioprine

for allergic contact dermatitis, [28](#)

for alopecia areata, [32](#)

for atopic dermatitis, [56](#), [61](#)

for autoimmune progesterone dermatitis, [72](#)

for Behçet disease, [92](#)

for bullous pemphigoid, [116](#), [118](#)

for chronic actinic dermatitis, [156](#)

for discoid eczema, [208](#)

for epidermolysis bullosa acquisita, [231](#)
for erythema multiforme, [243](#)
for hydroa vacciniforme, [351](#)
for Langerhans cell histiocytosis, [409](#)
for leprosy reaction, [428](#)
for leukocytoclastic vasculitis, [431](#)
for lichen planus, [443](#)
 oral, [574–575](#)
for malignant atrophic papulosis, [481](#)
for mucous membrane pemphigoid, [519](#)
for pemphigoid gestationis, [664](#)
for pemphigus, [614](#)
for pemphigus vulgaris, [613–614](#)
for polymorphic light eruption, [644](#)
for pompholyx, [321](#)
for pretibial myxedema, [670](#)
for prurigo nodularis, [675](#)
for psoriasis, [704](#)
for psoriatic erythroderma and bullous pemphigoid, [252](#)
for pyoderma gangrenosum, [714](#)
for relapsing polychondritis, [734](#)
for rheumatoid arthritis-associated vasculitis, [431](#)
for sarcoidosis, [752](#), [755](#)
for subacute cutaneous lupus erythematosus, [799](#)
for Sweet syndrome, [809](#)
for systemic sclerosis, [766](#)

Azelaic acid

for acne vulgaris, [9](#)

- for alopecia areata, [33](#)
- for comedonal acne, [641](#)
- for hyperpigmentation, [660–661](#)
- for melasma, [494](#)
- for perioral dermatitis, [620](#)
- for rosacea, [745](#)

Azelastine, for mastocytoses, [490](#)

Azithromycin

- for bacillary angiomatosis, [74](#)
- for Behçet disease, [93](#)
- for cat scratch disease, [134](#)
- for chancroid, [144](#)
- for confluent and reticulated papillomatosis, [162](#)
- for erythema migrans, [466](#)
- for gonorrhea, [295](#)
- for granuloma inguinale, [309–310](#)
- for granulomatous cheilitis, [314–315](#)
- for lymphogranuloma venereum, [475](#)
- for Mediterranean spotted fever, [741](#)
- for pityriasis lichenoides et varioliformis acuta, [637](#)
- for rosacea, [746](#)
- for yaws, [625](#)

Azoles

- for paracoccidioidomycosis, [594](#)
- for pityriasis versicolor, [827](#)
- for skin dermatophytosis, [821](#)
- for tinea capitis, [816](#)
- for tinea pedis, [820](#)

B

B cell deficiency, yellow nail syndrome and, [882](#)

Babesiosis, [102](#)

Bacillary angiomatosis, [73–75](#), [73f](#)

Bacillus anthracis, [97](#)

Bacillus Calmette-Guerin, for warts, [854](#)

Backhousia citriodora (Australian lemon myrtle) oil, for molluscum contagiosum, [510](#)

Bacon therapy, for myiasis, [539](#)

Balanitis, [76–78](#), [76f](#)

Balanitis xerotica obliterans, [76–77](#)

Barrier creams

- for diaper dermatitis, [203](#)

- for health care workers, hands of, [379](#)

- for pruritus vulvae, [688](#)

- side effects of, [379](#)

Barrier repair products, for atopic dermatitis, [54](#), [60](#)

Bartonella

- bacillary angiomatosis from, [73](#)

- cat scratch disease from, [134](#)

Basal cell carcinoma, [79–83](#), [79f](#)

- chemoprevention of, [565–566](#)

- nevroid basal cell carcinoma syndrome in, [562](#)

- nevus sebaceus in, [567](#)

- radiation exposure and, [719](#)

- rhinophyma and, [738](#)

Basal cell nevus syndrome, *See* [Nevroid basal cell carcinoma syndrome](#)

Baseline nail disease, [545](#)

Basiliximab, for scleroderma, [764](#)

Bath oils, for xerosis, [878](#)

Bcl-2 antisense, for melanoma, [488](#)

“Bean-bag cells,” [585](#)

Becaplermin

- for hemangiomas, [324](#)
- for necrobiosis lipoidica, [551](#)
- for pyoderma gangrenosum, [714](#)

Becker nevus, [84–86](#), [84f](#)

Beclomethasone, for pyoderma gangrenosum, [711–712](#)

Bed bug-detecting canines, [88–89](#), [591](#)

Bed bug traps, [88](#)

Bed bugs, [87–89](#), [87f](#), [591](#)

- monitors, [88–89](#), [591](#)

Behavior therapy, for trichotillomania, [837](#)

Behçet disease, [90–93](#), [90f](#)

- erythema nodosum due to, [247](#)
- pseudofolliculitis barbae and, [691](#)
- pyoderma gangrenosum and, [714](#)

Belimumab, for subacute cutaneous lupus erythematosus, [801](#)

Benign cutaneous polyarteritis, *See* [Cutaneous polyarteritis nodosa](#)

Benign familial pemphigus (Hailey-Hailey disease), [316–318](#), [316f](#)

Benign migratory glossitis (geographic tongue), [291](#)

Benzathine penicillin

- for Behçet disease, [93](#)
- for erythema nodosum, [247](#)
- for pinta and yaws, [624](#)

- for syphilis, [812](#)
- for yaws, [625](#)
- Benzodiazepines, for psychogenic excoriation, [708](#), [710](#)
- Benzoyl peroxide
 - for acne vulgaris, [8–9](#)
 - for comedonal acne, [641](#)
 - for pitted and ringed keratolysis, [627](#)
 - for pseudofolliculitis barbae, [692–693](#)
 - for rosacea, [745](#)
 - for seborrheic eczema, [773](#)
- Benzydamine, for postherpetic neuralgia, [342](#)
- Benzyl alcohol lotion, for pediculosis capitis, [607](#)
- Benzyl benzoate
 - for rosacea, [747](#)
 - for scabies, [757](#), [759](#)
- Benzylpenicillin
 - for acute generalized exanthematous pustulosis, [25](#)
 - for cellulitis, [139](#)
- Beraprost, for Raynaud's phenomenon, [724](#)
- Berloque dermatitis, [659](#)
- Beta-blockers, for hemangiomas, [322](#)
- Beta-carotene
 - See also* [Carotene](#)
- Betamethasone
 - for acne keloidalis nuchae, [5](#)
 - for allergic contact dermatitis, [28](#)
 - for alopecia areata, [30](#), [33](#)
 - for irritant contact dermatitis, [379–380](#)

for lichen planus, [442](#)
for miliaria rubra, [506](#)
for morphea, [514](#)
for nail psoriasis, [544](#)
for necrobiosis lipoidica, [549](#)
for palmoplantar keratoderma, [580](#)
for paronychia, [601](#)
for pretibial myxedema, [669](#)
for prurigo nodularis, [673](#)
for psoriasis, [700](#)
for scleromyxedema, [434](#)
for seborrheic eczema, [774](#)
for urticaria pigmentosa, [490](#)

Betel leaf (*Piper betle*), for myiasis, [539–540](#)

Bevacizumab

for hereditary hemorrhagic telangiectasia, [331](#)
for Kaposi sarcoma, [392](#)
for neurofibromatosis type 1, [561](#)
for pseudoxanthoma elasticum, [696](#)

Bexarotene

for alopecia areata, [33](#)
for irritant contact dermatitis, [379](#)
for lymphomatoid papulosis, [480](#)
for mycosis fungoides, [254](#), [535](#)
for Sézary syndrome, [254](#)

Bichloroacetic acid, for sebaceous hyperplasia, [770](#)

Bifonazole

for cutaneous candidiasis, [172](#)

- for diaper dermatitis, [172](#)
 - for erythrasma, [248](#)
 - for rosacea, [746](#)
- Bilastine, for chronic urticaria, [841t](#)
- Bile acid
- for cholestatic pruritus, [680](#)
 - for erythropoietic protoporphyria, [263](#)
 - for intrahepatic cholestasis of pregnancy, [665](#)
- Bimatoprost, for alopecia areata, [30–31](#)
- Bioengineered living cellular construct, for diabetic foot ulcers, [415](#)
- Biofeedback
- for hyperhidrosis, [357](#)
 - for Raynaud's phenomenon, [723](#)
- Bioflavonoids, for capillaritis, [132–133](#)
- Biologic agents
- for discoid lupus erythematosus, [210](#)
 - for erythrodermic psoriasis, [253–254](#)

Chromoblastomycosis, [150–153](#), [150f](#)

Chronic actinic dermatitis, [154–157](#), [154f](#)

Chronic bullous disease of childhood, [452](#)

Chronic inducible urticaria, [842](#)

Chronic infantile neurological cutaneous and articular syndrome (CINCA), [165](#)

Chronic mucocutaneous candidiasis, [171f](#), [172](#)

Chronic paronychia, [600](#)

Chronic plaque psoriasis, [545](#)

Chronic spontaneous urticaria, [841–842](#)

Chronic venous ulcers, [415](#)

Chrysaora quinquecirrha (sea nettle), [382](#)

Chylous pleural effusion, yellow nail syndrome and, [882](#)

Cicatricial pemphigoid, [517](#)

Ciclopir oxolamine, for seborrheic eczema, [771](#)

Ciclopirox

- for diaper dermatitis, [171](#)
- for onychomycosis, [824–825](#)
- for pityriasis versicolor, [827](#)
- for seborrheic eczema, [772–773](#)
- for tinea pedis, [820–821](#)

Ciclosporin, [292](#)

- for actinic prurigo, [20](#)
- for allergic contact dermatitis, [28](#)
- for alopecia areata, [31](#)
- for aphthous stomatitis, [52](#)
- for aquagenic pruritus, [375](#)
- for atopic dermatitis, [56](#), [61–62](#), [208](#)
- for Behçet disease, [92](#)
- for bullous pemphigoid, [119](#)
- for capillaritis, [133](#)
- for chronic actinic dermatitis, [156](#)

for chronic hand eczema, [321](#)
for chronic spontaneous urticaria, [841](#)
for cutaneous vasculitis, [431](#)
for cytophagic histiocytic panniculitis, [588](#)
for Darier disease, [180](#)
for dermatitis herpetiformis, [192](#), [194](#)
for dermatomyositis, [201](#)
for eosinophilic fasciitis, [216](#), [218](#)
for epidermolysis bullosa acquisita, [231](#)
for erythema elevatum diutinum, [241](#)
for erythema multiforme, [244](#)
for erythrodermic psoriasis, [252](#)
for folliculitis, [279](#)
for graft-*versus*-host disease, [299](#)
for granuloma annulare, [305](#)
for Hailey-Hailey disease, [317](#)
for hidradenitis suppurativa, [346](#)
for hydroa vacciniforme, [351](#), [353](#)
for impetigo herpetiformis, [698](#)
for irritant contact dermatitis, [379–380](#)
for Kawasaki disease, [397](#)
for leprosy, [427](#)
for leprosy reactions, [426–427](#)
for lichen nitidus, [437](#)
for lichen sclerosus, [447](#)
for lupus panniculitis, [587](#)
for malignant atrophic papulosis, [481–482](#)
for morphea, [514](#)

for mucous membrane pemphigoid, [519](#)
for ocular rosacea, [751](#)
for oral lichen planus, [574–576](#)
for palmoplantar pustulosis, [583](#)
for papular urticaria, [592](#)
for pemphigus, [612](#)
for pityriases rubra pilaris, [630](#)
for pityriasis lichenoides chronica, [637](#)
for pityriasis lichenoides et varioliformis acuta, [636–637](#)
for polymorphic light eruption, [645](#)
for prurigo nodularis, [675](#)
pseudofolliculitis barbae associated with, [692](#)
for psoriasis, [697–699](#), [701–702](#)
 erythrodermic, [705](#)
 monitoring guidelines for, [698–699](#)
 pustular, [706](#)
for pyoderma gangrenosum, [712](#), [714](#)
for reactive arthritis, [728](#)
for relapsing polychondritis, [734](#)
for rosacea, [750](#)
for sarcoidosis, [756](#)
for scleredema, [761](#), [763](#)
for scleroderma, [764](#)
for scleromyxedema, [434](#)
sebaceous hyperplasia as side effect of, [770](#)
for Stevens-Johnson syndrome, [214–215](#), [831](#)
for subcorneal pustular dermatosis, [803](#)
for Sweet syndrome, [808](#)

for systemic sclerosis, [767](#)
for toxic epidermal necrolysis, [831](#)
for Wells syndrome, [868–869](#)

Cidofovir

for condyloma acuminata, [290](#)
for herpes genitalis, [335](#)
for herpes labialis, [337](#), [339](#)
for molluscum contagiosum, [508](#)
for orf, [577–578](#)
for smallpox, [96](#)
for vaccinia or cowpox viruses, [96](#)
for warts, [857](#)

Cilastatin

for actinomycosis, [22](#)
for cellulitis and erysipelas, [141](#)

Cilostazol, livedoid vasculopathy, [462–463](#)

Cimetidine

alcohol-induced flushing, [273](#)
for eosinophilic fasciitis, [216](#), [218](#)
for erythema multiforme, [244](#)
for erythropoietic protoporphyria, [261–262](#)
for juvenile dermatomyositis, [125](#)
for mastocytoses, [490](#)
for molluscum contagiosum, [511](#)
for porphyria cutanea tarda, [652](#)
for warts, [854](#)
xerosis and, [879](#)

Cimex lectularius, [87](#)

Cinacalcet, for calciphylaxis, [128–129](#)

Cinryze, for hereditary angioedema, [328](#)

Ciprofloxacin

for actinomycosis, [23](#)

for anthrax, [97](#)

for bacillary angiomatosis, [74](#)

for cat scratch disease, [135](#)

for cellulitis, [141](#)

for chancroid, [144](#)

for dissecting cellulitis of scalp, [212](#)

for erysipelas, [141](#)

for folliculitis, [279](#)

for granuloma inguinale, [309–310](#)

for *Mycobacterium chelonae* infection, [530](#)

for *Mycobacterium fortuitum* infection, [530t](#)

for plague, [99](#)

for tularemia, [98](#)

Circumcision

in balanitis, [76](#)

for lichen sclerosus, [446](#)

Cisplatin

for extramammary Paget disease, [266](#)

for squamous cell carcinoma, [784](#)

Citalopram, for body dysmorphic disease, [110–111](#)

Cladribine

for juvenile xanthogranuloma, [390](#)

for mastocytoses, [492](#)

Clarithromycin

- for bacillary angiomatosis, [74](#)
- for confluent and reticulated papillomatosis, [161](#)
- for erythrasma, [248–249](#)
- for fish tank granuloma, [526–527](#)
- for leprosy, [426](#)
- for Mediterranean spotted fever, [741](#)
- for *Mycobacterium abscessus* infection, [530t](#), [531](#)
- for *Mycobacterium chelonae* infection, [530](#)
- for *Mycobacterium fortuitum* infection, [530t](#)
- for *Mycobacterium ulcerans* infection, [528–529](#)
- for palmoplantar pustulosis, [582](#)
- for prurigo pigmentosa, [677](#)
- for rosacea, [747](#)
- for yellow nail syndrome, [881](#)

Classic pityriasis rubra pilaris, treatment of, [253](#)

Clavulanic acid, for paronychia, [601](#)

Cleansing, for pruritus ani, [686](#)

Climbup Interceptor, for bed bugs, [88](#)

Clindamycin

- for acne keloidalis nuchae, [4](#)
- for acne vulgaris, [8–9](#)
- for actinomycosis, [22](#)
- for erythrasma, [248](#)
- for folliculitis decalvans, [281–282](#)
- for Fox-Fordyce disease, [284–285](#)
- for hidradenitis suppurativa, [344–346](#)
- for methicillin-resistant *Staphylococcus aureus*, [279](#)
- for MRSA, [287](#), [499](#), [501](#)

for paronychia, [601](#)
for perioral dermatitis, [620](#)
for pitted and ringed keratolysis, [626–627](#)
for pseudofolliculitis barbae, [692–693](#)
for rosacea, [745](#)

Clobetasol

for acne keloidalis nuchae, [5](#)
for actinic prurigo, [19](#)
for alopecia areata, [30](#)
for balanitis, [77](#)
for bullous pemphigoid, [116](#)
for erosive pustular dermatosis, [233](#)
for erythema multiforme, [243](#)
for granuloma annulare, [303](#)
for Jessner lymphocytic infiltrate, [385](#)
for lichen sclerosus, [446](#)
for lichen simplex chronicus, [449–450](#)
for lupus erythematosus profundus, [586](#)
for lymphomatoid papulosis, [479](#)
for mucous membrane pemphigoid, [517](#)
for nail psoriasis, [544](#)
for oral lichen planus, [575](#)
for palmoplantar pustulosis, [583](#)
for paronychia, [600](#)
for polymorphic eruption of pregnancy, [662](#)
for psoriasis, [699–700](#)
for reactive arthritis, [727](#)
for sarcoidosis, [756](#)

for seabather's eruption, [383](#)

for seborrheic eczema, [774](#)

for vitiligo, [860](#)

in vitiligo, [363](#)

Clobetasone butyrate, for balanitis, [77](#)

Clofazimine

for aphthous stomatitis, [52](#)

for erythema dyschromicum perstans, [238](#), [238t](#)

for granuloma faciale, [308](#)

for granulomatous cheilitis, [312](#), [314](#)

for leprosy, [426](#)

for Melkersson-Rosenthal syndrome, [314](#)

for necrobiosis lipoidica, [549](#)

for pyoderma gangrenosum, [714](#)

for Sweet syndrome, [808](#)

Clomipramine

for body dysmorphic disorder, [112](#)

for psychogenic excoriation, [708](#), [710](#)

for trichotillomania, [837](#)

Clonazepam

for burning mouth syndrome, [122](#)

for hyperhidrosis, [357](#)

Clonidine

for flushing, [273](#)

for hyperhidrosis, [356](#)

for rosacea, [749–750](#)

Clothing

body lice, [609](#)

- for Lyme disease prevention, [464](#)
- for miliaria, [505](#), [507](#)
- polymorphic light eruption and, [644](#)
- Rocky Mountain spotted fever and, [739](#)
- xeroderma pigmentosum and, [873–874](#)

Clothing louse (*Pediculus humanus*), [606](#)

Clotrimazole

- for diaper dermatitis, [204](#)
- for erythrasma, [248](#)
- for paronychia, [601](#)
- for pitted and ringed keratolysis, [626](#)

Clotrimazole-betamethasone dipropionate, for diaper dermatitis, [204](#)

Coagulation abnormalities, livedoid vasculopathy, [460–461](#)

Cobimetinib, for melanoma, [484–485](#), [487](#)

Coccidioides, [158](#)

Coccidioidomycosis, [158–160](#), [158f](#)

Cognitive behavior therapy (CBT)

- for body dysmorphic disease, [112](#)
- for burning mouth syndrome, [122](#)
- for psychogenic excoriation, [708](#), [710](#)
- for vulvodynia, [865–866](#)

Colchicine

- for α_1 -antitrypsin deficiency panniculitis, [589](#)
- for aphthous stomatitis, [51](#)
- for Behçet disease, [90](#)
- for calcinosis cutis, [124](#)
- for capillaritis, [133](#)
- for cutaneous leukocytoclastic vasculitis, [430](#)

- for dermatitis herpetiformis, [194](#)
- for epidermolysis bullosa acquisita, [229](#), [231](#)
- for erythema elevatum diutinum, [239](#)
- for erythema nodosum, [246](#)
- for linear IgA bullous dermatosis, [451–452](#)
- for nodular vasculitis, [587](#)
- for psoriasis, [704](#)
 - pustular, [707](#)
- for pyoderma gangrenosum, [714](#)
- for relapsing polychondritis, [734](#)
- for Schamberg's disease, [133](#)
- for scleredema, [762](#)
- for scleroderma, [766](#)
- for Sweet syndrome, [807](#)

Cold avoidance, for livedo reticularis, [457](#)

Cold-induced pain, in cutaneous leiomyoma, [417](#)

Cold urticaria, in aquagenic pruritus, [375](#)

Colesevelam, for cholestatic pruritus, [680](#)

Collagen

- for acne vulgaris, [11](#)
- for angular cheilitis, [45](#)
- for pseudoxanthoma elasticum, [696](#)

Collagen sealant injection, for stoma care, [792](#)

Colloidal oatmeal skin protectant, for xerosis, [880](#)

Colonoscopy, for gastrointestinal polyps, [621](#)

Colorectal neoplasm, pruritus ani and, [687](#)

Colorimetric evaluation, for chloasma, [659–660](#)

Colostomies, [790](#)

Combination therapy, for psoriasis, [698](#), [703](#)

Combined oral contraceptives (OCPs)

- for acne, [641](#)
- for hirsutism, [359](#), [641](#)
- for polycystic ovary syndrome, [640](#)

Combined UVA1-retinoid-corticosteroid treatment, for eosinophilic fasciitis, [218](#)

Complete decongestive physiotherapy, *See* [Complex decongestive therapy](#)

Complex decongestive therapy (CDT)

- contraindications to, [471](#)
- for lymphedema, [470](#)
- for pretibial myxedema, [668](#), [670](#)

Complex regional pain syndrome, [10217#f0010](#), [730–732](#)

- differential diagnoses, [730](#)
- management strategy for, [730–731](#)
- prevention of, [730–732](#)
- signs and symptoms of, [730](#)

Compression

- for jellyfish stings, [383](#)
- for lipodermatosclerosis, [454](#)
- for lymphedema, [471](#)
- for pretibial myxedema, [668–669](#)
- for venous leg ulcers, [414–415](#)

Condoms, for herpes genitalis prevention, [336](#)

Condyloma acuminata, [288–290](#), [288f](#)

Condylomata lata, [811](#)

Confectioner's sugar, in MRSA, [503](#)

Confluent and reticulated papillomatosis, [161–164](#), [161f](#)

Confocal scanning laser microscopy, for sebaceous hyperplasia, [770](#)

Congenital adrenal hyperplasia, acanthosis nigricans with, [2](#)

Congenital erythrodermic psoriasis, [251](#)

Congenital linear Becker's nevus, [86](#)

Conglobate acne, *See* [Acne vulgaris](#)

Conjunctivitis, xeroderma pigmentosum and, [875](#)

Connexin gene mutations, erythrokeratoderma and, [255](#)

Contact allergens, in pompholyx, [320](#)

Contact dermatitis

- as erythema annulare centrifugum, [235](#)
- pigmented, [659](#)
- pruritus ani and, [686](#)

Contact hypersensitivity, in patients, with orofacial granulomatosis, [313](#)

Continuous-wave/pulsed carbon dioxide laser, for pyogenic granuloma, [717](#)

Contractures, dermatomyositis and, [198](#)

Cooling lotions, for intrahepatic cholestasis of pregnancy, [665](#)

Copaiba oil, for acne vulgaris, [9](#)

Copper bromide laser, for striae, [795](#)

Copper vapor laser, for Fabry disease, [270](#)

Cor806.805 (Tetrix cream), for irritant contact dermatitis, [379](#)

Cordylobia anthropophaga (tumbu fly), myiasis and, [538](#)

Corticosteroids

- for acanthosis nigricans, [2](#)
- for acne keloidalis nuchae, [4](#)
- for actinic prurigo, [20](#)
- for acute generalized exanthematous pustulosis, [25](#)
- for allergic contact dermatitis, [27](#)

for alopecia areata, [30–31](#)
for amyloidosis, [34](#)
for angioedema, [843](#)
for angiolymphoid hyperplasia with eosinophilia, [41](#)
for antiphospholipid syndrome, [48](#)
for aphthous stomatitis, [50](#)
for atopic dermatitis, [55](#), [58](#)
for atopic eruption of pregnancy, [667](#)
for autoimmune progesterone dermatitis, [70](#)
for balanitis, [77](#)
for Behçet disease, [90](#)
for bullous pemphigoid, [117](#)
for calcinosis cutis, [125](#)
for calciphylaxis, [129](#)
for capillaritis, [131](#)
for chilblains, [146](#)
for chondrodermatitis nodularis helices chronicus, [147](#)
for chronic actinic dermatitis, [154](#)
for complex regional pain syndrome, [732](#)
for cryoglobulinemic vasculitis, [432](#)
for cryopyrin associated periodic syndromes, [165](#), [167](#)
for cutaneous candidiasis, [171](#)
for cutaneous polyarteritis nodosa, [177](#)
for dermatitis herpetiformis, [192](#)
for dermatomyositis, [198](#)
for diaper dermatitis, [204](#)
for diffuse cutaneous systemic sclerosis, [766](#)
for discoid eczema, [206](#)

for discoid lupus erythematosus, [209](#)
for dissecting cellulitis of scalp, [211](#)
for eosinophilic fasciitis, [216](#)
for epidermolysis bullosa acquisita, [230](#)
for erosive pustular dermatosis, [233](#)
for erythema annulare centrifugum, [237](#)
for erythema dyschromicum perstans, [238](#), [238t](#)
for erythema elevatum diutinum, [239](#)
for erythema multiforme, [243](#)
for erythroderma, [250](#), [253](#)
for erythrokeratoderma, [257](#)
for erythrokeratoderma variabilis, [256](#)
for follicular mucinosis, [275](#)
for folliculitis decalvans, [281](#)
for Fox-Fordyce disease, [284](#)
for geographic tongue, [291](#)
for Gianotti-Crosti syndrome, [294](#)
for graft-*versus*-host disease
 acute, [299](#)
for granuloma annulare, [303](#)
for granuloma faciale, [308](#)
for granulomatous cheilitis, [312](#)
for Grover disease, [834](#)
for Hailey-Hailey disease, [316](#)
for hemangiomas, [322–324](#)
for herpes labialis, [338](#)
for herpes zoster, [340](#)
for inflammatory linear verrucous epidermal nevus, [222](#)

for irritant contact dermatitis, [379](#)
for Jessner lymphocytic infiltrate, [384](#)
for juvenile xanthogranuloma, [390](#)
for Kawasaki disease, [397](#)
for keloids, [398–399](#)
for keratosis pilaris, [405](#)
for lichen planopilaris, [438](#)
for lichen planus, [441](#)
for lichen simplex chronicus, [448](#)
for linear IgA bullous dermatosis, [451](#)
for lupus pernio, [754](#)
for lymphomatoid papulosis, [479](#)
for mastocytomas, [490](#)
for morphea, [513](#)
for mucous membrane pemphigoid, [517](#)
for mycosis fungoides, [533–535](#)
for necrobiosis lipoidica, [549](#)
for notalgia paresthetica, [569](#)
for oral lichen planus, [574–575](#)
for palmoplantar keratoderma, [579](#)
for palmoplantar pustulosis, [582](#)
for papular urticaria, [590](#), [592](#)
paraneoplastic pemphigus, [612](#)
for paronychia, [600–601](#)
for pemphigoid gestationis, [663–665](#)
for pemphigus, [612](#)
for pityriasis lichenoides, [636](#)
for pityriasis lichenoides chronica, [632](#)

for pityriasis lichenoides et varioliformis acuta, [635](#)
for pityriasis rosea, [639](#)
for polymorphic eruption of pregnancy, [662](#)
for pompholyx, [319](#)
for porokeratoses, [646](#)
for postherpetic neuralgia, [343](#)
for pretibial myxedema, [668–669](#)
for prurigo nodularis, [672](#)
for pruritus ani, [687](#)
for pruritus vulvae, [688](#), [690](#)
for psoriasis, [697](#), [704](#)
 erythrodermic, [705](#)
 inverse, [698](#)
 pustular, [707](#)
 side effects of, [700](#)
for psychogenic excoriation, [708](#)
for pyoderma gangrenosum, [712](#)
for pyogenic granuloma, [718](#)
for radiation dermatitis, [719](#)
for reactive arthritis, [726](#), [728](#)
for rosacea, [750](#)
for rosacea fulminans, [751](#)
safety in pregnancy, [663](#)
for sarcoidosis, [752–753](#)
for scleredema, [761](#)
for seborrheic eczema, [771](#)
for Stevens-Johnson syndrome, [832](#)
for stoma care, [790](#)

- for striae, [794](#)
- for subacute cutaneous lupus erythematosus, [797](#)
- for subcorneal pustular dermatosis, [802–803](#)
- for subcutaneous fat necrosis of newborn, [805–806](#)
- for Sweet syndrome, [807](#)
- teratogenicity of, [664](#)
- for toxic epidermal necrolysis, [832](#)
- in toxic shock syndrome, [252](#)
- for urticaria, [841](#)
- for urticaria pigmentosa, [490](#)
- for varicella, [845](#)
- for vitiligo, [861–862](#)
- for Wells syndrome, [868–869](#)
- for xerosis, [879](#)

Corynebacterium minutissimum

- antibiotic susceptibility of, [249](#)
- erythrasma from, [248](#)

Cosmetic camouflage, [364](#)

- rosacea and, [744](#)

Cotrimoxazole, for *Mycobacterium fortuitum* infection, [530t](#)

Counseling

- drug eruptions and, [213–214](#)
- genetic, for nevoid basal cell carcinoma syndrome, [562](#)
- for herpes genitalis, [333](#), [336](#)
- for irritant contact dermatitis, [378](#)
- for polycystic ovary syndrome, [640](#)

Cowpox virus, [96](#)

Coxiella burnetii, [743](#)

Coxsackievirus A16, [851](#)

Crab louse (*Phthirus pubis*), [606](#), [609](#)

Crab yaws, [624](#)

Craniofacial hyperhidrosis, [354](#)

“Creeping eruption,” [175](#)

Crisaborole, for atopic dermatitis, [59](#)

Crohn’s disease

- epidermolysis bullosa acquisita and, [230](#)
- erythema nodosum and, [247](#)
- granulomatous cheilitis and, [312](#)
- orofacial granulomatosis associated with, [312–313](#)
- Sweet syndrome and, [808](#)

Cromolyn sodium, for mastocytoses, [490](#)

Crotamiton

- for pediculosis capitis, [608](#)
- for rosacea, [747](#)
- for scabies, [757–759](#)

Cryoanalgesia, for postherpetic neuralgia, [342](#)

Cryofiltration, for calciphylaxis, [130](#)

Cryogenic spray, for port wine stain, [654](#)

Cryoglobulinemic vasculitis, [431](#)

Cryopyrin associated periodic syndromes (CAPS), [165–167](#), [165f](#)

Cryosurgery/cryotherapy

- for actinic keratoses, [15](#)
- for alopecia areata, [32](#)
- for angiolymphoid hyperplasia with eosinophilia, [41](#)
- for basal cell carcinoma, [80](#)
- for Bowen’s disease, [115](#)

for chromoblastomycosis, [150](#), [152](#)
for condyloma acuminata, [290](#)
for cutaneous larva migrans, [176](#)
for elastosis perforans serpiginosa, [618](#)
for granuloma annulare, [303](#)
for granuloma faciale, [308](#)
for Kaposi sarcoma, [392](#)
for keloids, [398–399](#)
for keratoacanthoma, [403](#)
for leishmaniasis, [420–421](#)
for lentigo maligna, [424](#)
for lymphocytoma cutis, [474](#)
for mucocoeles, [515](#)
for myxoid cyst, [541](#)
for nevoid basal cell carcinoma syndrome, [564](#)
for orf, [577](#)
for porokeratoses, [646](#)
for prurigo nodularis, [674](#)
for psoriasis, [704](#)
for pyogenic granuloma, [716–717](#)
for rhinophyma, [738](#)
for sebaceous hyperplasia, [769](#), [769](#)
for seborrheic keratosis, [775–776](#)
for sporotrichosis, [779](#)
for squamous cell carcinoma, [780–781](#)
for steatocystoma multiplex, [789](#)
for syringomata, [814–815](#)
for verrucous epidermal nevus, [221](#)

for warts, [852–853](#), [855](#)

for xeroderma pigmentosum, [874](#)

Cryptococcosis, [168–170](#), [168f](#)

CS20 protective barrier gel, for herpes labialis, [338](#)

CT

for actinomycosis, [21](#)

for Kawasaki disease, [395](#)

for lymphedema, [470](#)

for Merkel cell carcinoma, [496](#)

for relapsing polychondritis, [733](#)

for squamous cell carcinoma, [782](#)

Culture

for furunculosis, [286](#)

for geographic tongue, [291](#)

for hidradenitis suppurativa, [344](#)

for histoplasmosis, [347](#)

for leishmaniasis, [419–421](#)

from paracoccidioidomycosis, [594](#)

for sporotrichosis, [777](#)

Curaçao criteria, for hereditary hemorrhagic telangiectasia, [329](#), [329t](#)

Curcumin, for radiation dermatitis, [720](#)

Curcuminoids, for oral lichen planus, [574](#), [576](#)

Curettage

for basal cell carcinoma, [80](#)

for Bowen's disease, [115](#)

for chondrodermatitis nodularis helices chronicus, [149](#)

for Fox-Fordyce disease, [285](#)

for keratoacanthoma, [403](#)

- for molluscum contagiosum, [509](#)
- for seborrheic keratosis, [775–776](#)
- for syringomata, [815](#)

Curettage and electrodesiccation

- for basal cell carcinoma, [563](#)
- for molluscum contagiosum, [508](#)
- for pyogenic granuloma, [716](#)
- for squamous cell carcinoma, [780](#)

Cushing syndrome, striae and, [794](#)

Cutaneous candidiasis, [171](#)

Cutaneous field stimulation, in notalgia paresthetica, [569](#)

Cutaneous hemangiomas, [322](#)

Cutaneous larva migrans, [175–176](#), [175f](#)

Cutaneous leiomyomata, [416](#)

Cutaneous leishmaniasis (CL), vaccine for, [418](#)

Cutaneous lupus erythematosus, [209–210](#)

Cutaneous manifestations, of mastocytoses, [489–492](#)

Cutaneous myiasis, [10162#s0040](#)

Cutaneous polyarteritis nodosa, [177–178](#), [177f](#)

Cutaneous small vessel vasculitis, [429](#)

Cutaneous smooth muscle neoplasms, [416–417](#)

Cutaneous T-cell lymphoma (CTCL), erythrodermic, diagnosing, [251–254](#)

Cuterebra, myiasis and, [538](#)

Cutis marmorata, [457](#)

Cutis marmorata telangiectatica congenita, [457](#)

Cyclomethicone, for pediculosis capitis, [608](#)

Cyclophosphamide

- for Behçet disease, [92](#)

- for bullous pemphigoid, [118](#)
- for cytophagic histiocytic panniculitis, [588](#)
- for diffuse cutaneous systemic sclerosis, [765–766](#)
- for mucous membrane pemphigoid, [518](#)
- for pemphigoid gestationis, [664–665](#)
- pemphigus, [612](#)
- pemphigus vulgaris, [614](#)
- for pyoderma gangrenosum, [713](#)
- for relapsing polychondritis, [734](#)
- for scleroderma, [768](#)
- for scleromyxedema, [434](#)
- for subacute cutaneous lupus erythematosus, [800](#)
- for Sweet syndrome, [808](#)
- for systemic sclerosis, [766](#)
 - interstitial lung disease with, [766–768](#)
- for toxic epidermal necrolysis, [831](#)

Cyclosporin(e), *See* [Ciclosporin](#)

Cyproterone acetate

- for acne, [641](#)
- for acne vulgaris, [9–10](#)
- for androgenetic alopecia, [39](#)
- for hidradenitis suppurativa, [344](#)
- for hypertrichosis, [359](#)

Cysteine, for erythropoietic protoporphyria, [262](#)

Cytophagic histiocytic panniculitis, [585](#), [588–589](#)

Cytoreductive agents, for mastocytoses, [489](#), [492](#)

Cytotoxic agents, for pretibial myxedema, [668](#), [670](#)

Cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4), for melanoma, [484–485](#)

D

Dacarbazine, for melanoma, [484](#), [488](#)

Daclizumab

for bullous pemphigoid, [119](#)

for Sézary syndrome, [254](#)

Dactylitis, blistering distal, [108–109](#), [108f](#)

Dalbavancin, for MRSA, [502](#)

Danazol

for autoimmune progesterone dermatitis, [70](#)

for chronic actinic dermatitis, [157](#)

for hereditary angioedema, [327](#)

for lipodermatosclerosis, [456](#)

for livedoid vasculopathy, [462](#)

Dapsone

for α_1 -antitrypsin deficiency panniculitis, [589](#)

for acne fulminans, [247](#)

for acne vulgaris, [6](#), [8](#)

for aphthous stomatitis, [51](#)

for Behçet disease, [91](#)

for bullous pemphigoid, [118](#)

for dermatitis herpetiformis, [192](#)

for discoid lupus erythematosus, [210](#)

for eosinophilic fasciitis, [216](#), [218](#)

for epidermolysis bullosa acquisita, [230](#)

for erosive pustular dermatosis, [233](#)

for erythema dyschromicum perstans, [238](#), [238t](#)

in erythema elevatum diutinum, [239](#)

for erythema multiforme, [243](#)
for erythema nodosum, [247](#)
for febrile ulceronecrotic Mucha-Habermann disease, [636](#)
for follicular mucinosis, [275](#)
for folliculitis decalvans, [281–282](#)
for folliculitis spinulosa decalvans, [408](#)
for granuloma annulare, [303](#)
for Hailey-Hailey disease, [317](#)
for Henoch-Schönlein purpura, [430](#)
for hidradenitis suppurativa, [346](#)
for leprosy, [426](#)
for leukocytoclastic vasculitis, [432](#)
for linear IgA bullous dermatosis, [451](#)
for lupus erythematosus profundus, [587](#)
for mucous membrane pemphigoid, [517–521](#)
for pemphigoid gestationis, [665](#)
for pityriasis rosea, [639](#)
for prurigo pigmentosa, [676](#)
for pyoderma gangrenosum, [712](#)
for relapsing polychondritis, [734](#)
for sarcoidosis, [756](#)
for subacute cutaneous lupus erythematosus, [799](#)
for subcorneal pustular dermatosis, [802–803](#)
for Sweet syndrome, [808](#)
for Wells syndrome, [868–869](#)
Daptomycin, for MRSA, [502](#)
Darier disease, [179–180](#), [179f](#)
Darier-Ferrand, surgical treatment of, for dermatofibrosarcoma protuberans, [196](#)

Dark field microscopy

for syphilis, [811](#)

for yaws, [625](#)

Dartoid myoma, [416](#)

Daughter yaws, [624](#)

Dazoxiben, for Raynaud's phenomenon, [724](#)

De Santis-Cacchione syndrome, xeroderma pigmentosum and, [875](#)

Dead sea, psoriasis and, [700–701](#)

Death of Onchocerciasis and Lymphatic Filariasis (DOLF), [573](#)

Debridement

for calcinosis cutis, [126](#)

for decubitus ulcers, [184–185](#)

Deck-chair sign, [250](#)

Decompression, for chondrodermatitis nodularis helices chronica, [148](#)

Decongestive physiotherapy, for yellow nail syndrome, [882](#)

Decorative cosmetics, for rosacea, [748–749](#)

Decubitus ulcer, [181–186](#), [181f](#)

Deep tendon reflexes, in xeroderma pigmentosum, [875](#)

Deep ulcers, [182](#)

Deep vein thrombosis (DVT), in necrolytic migratory erythema, [554](#)

DEET (diethyl-*m*-toluamide), [104](#)

for bites and stings, [102](#)

for Lyme disease prevention, [464](#)

Deferasirox, for porphyria cutanea tarda, [651](#)

Deferoxamine, for porphyria cutanea tarda, [651–652](#)

Defibrotide, for granuloma annulare, [306](#)

Degos disease, [481–483](#), [481f](#)

Dehydrated human amniotic membrane allograft, for diabetic foot

- ulcers, [415](#)
- Delusional parasitosis, [708](#)
- Delusions of parasitosis, [187–189](#), [187f](#)
- Demodex* folliculitis, [278](#)
- Demodex folliculorum*, [747](#)
- Demodicidosis, rosacea-like, [747](#)
- Denileukin diftitox, [533](#)
- Dental infection, discoid eczema and, [207](#)
- 1-deoxygalactonojirimycin (migalastat), for Fabry disease, [268–269](#), [271](#)
- Depigmenting agents, [660](#), [660t](#)
 - for melasma, [493](#)
- Depilatory, for hirsutism, [358](#)
- Depression
 - with body dysmorphic disease, [111–113](#)
 - prurigo nodularis and, [672](#)
- Dermabrasion
 - for actinic keratoses, [14](#)
 - for amyloidosis, [34](#)
 - for Hailey-Hailey disease, [317](#)
 - of hyperkeratotic foot, [581](#)
 - for porokeratosis of Mibelli, [648](#)
 - for syringomata, [814–815](#)
 - for xeroderma pigmentosum, [874–875](#), [877](#)
- Dermal melasma, [493](#)
- Dermatitis
 - autoimmune progesterone, [70–72](#), [70f](#)
 - chronic actinic, [154–157](#), [154f](#)
 - decubitus, [182](#)

- diaper, [171](#), [203–205](#), [203f](#)
- estrogen, [71](#)
- radiation, [719–721](#), [719f](#)
- rat mite, [591](#)
- Dermatitis artefacta (DA), [190–191](#), [190f](#), [708](#)
- Dermatitis herpetiformis (DH), [192–194](#), [192f](#)
- Dermatitis perioralis, [747](#)
- Dermatobia hominis* (botfly), myiasis and, [538](#)
- Dermatofibroma, dermatofibrosarcoma protuberans *vs.*, [196](#)
- Dermatofibrosarcoma protuberans (DFSP), [195–197](#), [195f](#), [398–401](#)
- Dermatography, for alopecia areata, [32](#)
- Dermatologic nondisease, *See* [Body dysmorphic disorder](#)
- Dermatologic toxicities, to targeted cancer therapy, [408](#)
- Dermatome shaving, for xeroderma pigmentosum, [874–875](#)
- Dermatomyositis, [198–202](#), [198f](#)
 - calcinosis associated with, [124](#)
 - erythrodermic, associated with gastric cancer, [251](#)
 - panniculitis and, [585](#)
- Dermatophyte, erythroderma due to, [252](#)
- Dermatophyte Test Strip, [824](#)
- Dermatophytosis, [171](#)
 - palmoplantar keratoderma and, [579–580](#)
- Dermatoscopy, for lichen planopilaris, [438](#)
- Dermatosis, hypopigmented variants of, [362–363](#)
- Dermatosis papulosa nigra, [775–776](#)
- Dermonecrosis, jellyfish stings and, [383](#)
- Dermoscopy
 - for atypical nevi, [67](#)

- for melanoma, [484](#), [486](#)
- for paronychia, [602](#)
- for pediculosis capitis, [606–607](#)
- for pigmented purpuric dermatoses, [132](#)
- for porokeratoses, [646–649](#)
- for seborrheic eczema, [771](#)
- for trichotillomania, [836](#)
- for xeroderma pigmentosum, [875–877](#)

Desensitization

- to penicillin, for syphilis, [812](#)
- for polymorphic light eruption, [643](#)

Desferrioxamine, for porphyria cutanea tarda, [651](#)

Desipramine

- for postherpetic neuralgia, [341t](#)
- for vulvodynia, [865](#)

Desloratadine, for chronic urticaria, [841t](#)

Desmoglein, pemphigus, [611](#)

Detergents, avoidance of, xerosis and, [878](#)

Dexamethasone

- for aphthous stomatitis, [50](#)
- for bullous pemphigoid, [118](#)
- for cholestasis of pregnancy, [681](#)
- for cryptococcosis, [168–169](#)
- for granuloma faciale, [307](#)
- for papular urticaria, [592](#)
- for porokeratosis of Mibelli, [648](#)
- for scleromyxedema, [435](#)

Dextroamphetamine sulfate, for keratosis pilaris, [408](#)

Diabetes mellitus

- with bullous pemphigoid, [117](#)
- geographic tongue and, [291](#)
- granuloma annulare associated with, [302](#)
- lower extremity amputation and death, [415](#)
- necrobiosis lipoidica and, [548–549](#)
- palmoplantar pustulosis and, [582](#)
- in polycystic ovary syndrome, [640–641](#)
- prurigo pigmentosa caused by, [676](#)
- pruritus vulvae and, [689](#)
- reactive perforating collagenosis with, [616](#)
- scleredema and, [761](#)
- tinea pedis and, [822](#)
- xerosis and, [878–879](#)

Diabetic ketoacidosis, prurigo pigmentosa associated with, [676](#)

Diabetic neuropathy, [414](#)

Dialysis

- low-calcium, for calciphylaxis, [129](#)
- for nephrogenic systemic fibrosis, [557](#)

Diaper dermatitis, [171](#), [203–205](#), [203f](#)

Dichloromethane solution, for lichen simplex chronicus, [448](#)

Diclofenac

- for actinic keratoses, [16](#)
- for porokeratosis, [648](#)

Dicloxacillin, for cellulitis and erysipelas, [141](#)

Diet, *See* [Nutritional/dietary management](#)

Dietary fish oil

- for acanthosis nigricans, [3](#)

for hydroa vacciniforme, [351](#), [353](#)

Diethyl-m-toluamide (DEET), for bed bugs, [592](#)

Diethyl phenyl-acetamide (DEPA), for bed bugs, [592](#)

Diffuse and erythrodermic cutaneous mastocytosis, [489](#)

Diffuse cutaneous systemic sclerosis, [764–766](#)

Digital artery sympathectomy, for Raynaud's phenomenon, [725](#)

Digital infrared thermal imaging, for pretibial myxedema, [668–669](#)

Digital mucus cyst, *See* [Myxoid cyst](#)

Dihydroxyacetone, for erythropoietic protoporphyria, [261](#)

1 alpha 25-Dihydroxyvitamin D₃, *See* [Tacalcitol](#)

Diltiazem

- for calcinosis cutis, [125](#)
- for chilblains, [146](#)
- for dermatomyositis, [201](#)
- for hyperhidrosis, [357](#)
- for Raynaud's phenomenon, [723](#)

Dimethyl phthalate (DMP), for bed bugs, [592](#)

Dinitrochlorobenzene, for lichen nitidus, [437](#)

Diode laser

- for acne vulgaris, [10](#)
- for burning mouth syndrome, [123](#)
- for dissecting cellulitis of scalp, [212](#)
- for herpes labialis, [337](#)
- for keloids, [400](#)
- for keratosis pilaris, [406t](#)
- for lymphangioma circumscriptum, [469](#)
- oral lichen planus, [576](#)
- for pseudofolliculitis barbae, [693](#)

- for sebaceous hyperplasia, [770](#)
- for seborrheic keratosis, [776](#)
- for steatocystoma multiplex, [789](#)

Diphencyprone

- for alopecia areata, [30](#), [32](#)
- for molluscum contagiosum, [510](#)
- for viral warts, [852](#), [854](#)

Diphenhydramine

- alcohol-induced flushing, [273](#)
- for papular urticaria, [590](#)
- for polymorphic eruption of pregnancy, [663](#)

Diphenylcyclopropenone

- for alopecia areata, [29](#)
- for warts, [854](#)

Dipropionate, for lichen planus, [442](#)

Dipyridamole

- for livedoid vasculopathy, [461](#)
- for malignant atrophic papulosis, [481–482](#)
- for necrobiosis lipoidica, [548](#)
- for Raynaud's phenomenon, [724](#)

Direct immunofluorescence (DIF), for lupus panniculitis, [584](#)

Direct microscopy, [820](#)

Discharge, gonorrhea and, [295–297](#)

Discoid eczema, [206–208](#), [206f](#)

Discoid lupus erythematosus, [209–210](#), [209f](#), [797](#)

- lupus panniculitis and, [584](#)

Disodium cromoglycate, for mastocytoses, [489–490](#)

Dissecting cellulitis of scalp, [211–212](#), [211f](#)

Disseminated gonococcal infection, [295](#), [297](#)

Disseminated histoplasmosis, [347–349](#)

Disseminated superficial actinic porokeratosis, [646](#)

Distal subungual onychomycosis, [823](#)

Dithranol, *See* [Anthralin](#)

DNA testing, for xeroderma pigmentosum, [873](#)

Docetaxel

- for atypical fibroxanthoma, [65](#)
- for extramammary Paget disease, [266](#)

Docosanol, for herpes labialis, [337](#), [339](#)

Donovan bodies, [309](#)

Donovanosis, [309–311](#), [309f](#)

Doppler ultrasound, for morphea, [513](#)

Doughnut pillow, for chondrodermatitis nodularis helices chronicus, [148](#)

Doxazosin, for leiomyoma, [416](#)

Doxepin

- for discoid eczema, [207](#)
- for lichen simplex chronicus, [448](#)
- for psychogenic excoriation, [708–709](#)
- for renal itch, [682](#)

Doxorubicin

- for cytophagic histiocytic panniculitis, [588](#)
- for necrolytic migratory erythema, [556](#)

Doxycycline

- for α_1 -antitrypsin deficiency panniculitis, [589](#)
- for actinomycosis, [22](#)
- for anthrax, [97](#)

for bacillary angiomatosis, [74](#)
for confluent and reticulated papillomatosis, [162](#)
for epidemic typhus, [741](#)
erythema migrans borreliosis, [466](#)
for granuloma annulare, [305](#)
for granuloma inguinale, [309–310](#)
for Hailey-Hailey disease, [316–317](#)
for leishmaniasis, [418](#)
Lyme disease, [464](#), [466](#)
for lymphangioma circumscriptum, [468](#)
for lymphocytoma cutis, [472](#)
for lymphogranuloma venereum, [475–476](#)
for MRSA, [279](#), [499](#)
for murine typhus, [741](#)
for ocular rosacea, [751](#)
for onchocerciasis, [571–573](#)
for paronychia, [601](#)
for perioral dermatitis, [619](#)
for plague, [99](#)
for pompholyx, [319](#)
for prurigo pigmentosa, [677](#)
for Q fever, [742](#)
for reactive arthritis, [726](#)
for reactive perforating collagenosis, [617](#)
for rickettsial spotted fevers, [739](#)
for rickettsialpox, [742](#)
for rosacea, [745](#)
for rosacea lymphedema, [750](#)

- for scrub typhus, [741](#)
- for Sweet syndrome, [808](#)
- for syphilis, [811](#)
- for tularemia, [98](#)
- for yaws, [625](#)

Drainage

- of abscess, in MRSA, [500–501](#)
- for furunculosis, [286](#)
- for myxoid cyst, [541](#)

DRESS syndrome, [214](#)

Dressings

- for decubitus ulcers, [186](#)
- for epidermolysis bullosa, [226](#)
- for leg ulcers, [414](#)
- protective, for dermatitis artefacta, [190](#)

Driclor, for pitted and ringed keratolysis, [626](#)

Dronabinol (Δ^9 -tetrahydrocannabinol), for cholestatic pruritus, [681](#)

Drooling, angular cheilitis and, [45](#)

Drospirenone, for acne, [641](#)

Drug-associated/induced conditions

- in acute generalized exanthematous pustulosis, [24](#)
- in bullous pemphigoid, [117](#)
- in capillaritis, [131](#)
- in cicatricial pemphigoid, [117](#)
- in discoid eczema, [206](#)
- in lichenoid reaction, [574](#)
- in paronychia, [600](#)
- in pemphigoid, [117](#)

Drug eruptions, [213–215](#), [213f](#)

Drug hypersensitivity reaction, graft-*versus*-host disease, [298–300](#)

Drug-induced burning mouth syndrome, [121](#)

Drug-induced hypersensitivity syndrome (DIHS), human herpesvirus 6 and, [849](#)

Drug-induced purpura simplex, [132](#)

Drug-induced skin injury (DISI), [214–215](#)

Drug withdrawal, in acute generalized exanthematous pustulosis, [24](#), [25t](#)

“Dry flushing,” [272](#)

Duct tape, for warts, [857](#)

Duct tape occlusion, for molluscum contagiosum, [510](#)

Duloxetine

- for burning mouth syndrome, [122](#)
- for cutaneous leiomyoma, [417](#)

Dust mite reduction, for atopic dermatitis, [60](#)

Dutasteride

- for androgenetic alopecia, [39](#)
- for hirsutism, [359](#)

Dutch Cutaneous Lymphoma Group, [478](#)

Dye laser, for elastosis perforans serpiginosa, [618](#)

Dysesthesia, idiopathic flushing with, [274](#)

Dysmorphophobia, *See* [Body dysmorphic disorder](#)

Dysplastic nevi, [66–67](#), [66f](#)

Dysport, *See* [Botulinum toxin A](#)

Dystrophic psoriatic fingernails, [546](#)

E

Ear

chondrodermatitis nodularis helices chronicus in, [147](#), [147f](#)

relapsing polychondritis in, [733](#)

Ear lobe, lupus vulgaris of, [839](#)

Early onset prurigo of pregnancy (atopic eruption of pregnancy), [666–667](#)

Earrings, gold, lymphocytoma cutis reactions to, [473](#)

Ebastine, for mosquito-bite allergy, [592](#)

Ebola virus disease, [100–101](#)

Ecallantide, for hereditary angioedema, [327](#)

Eccrine glands

in hyperhidrosis, [354](#)

nonneoplastic disorders of, [505–507](#)

Echinacea, for warts, [858](#)

Echinocandins, for coccidioidomycosis, [159](#)

Echocardiography, for Kawasaki disease, [395](#)

Econazole nitrate, for tinea pedis, [821](#)

Ecthyma contagiosum, [577](#)

Ectropion of the lids, xeroderma pigmentosum and, [875](#)

Eculizumab

for antiphospholipid syndrome, [48](#)

for malignant atrophic papulosis, [481–482](#)

Edwardsiella lineata (sea anemone), [381–382](#)

Efinaconazole, for onychomycosis, [825–826](#)

Eflornithine

for facial hair, [641](#)

- for hirsutism, [359](#)
- for pseudofolliculitis barbae, [693](#)
- Ehrlichia chaffeensis*, [743](#)
- Ehrlichia equi*, [743](#)
- Ehrlichiosis, [743](#)
- Elastosis perforans serpiginosa, [616–618](#)
- Elective lymph node dissection, for melanoma, [486](#)
- Elective lymphadenectomy, for melanoma, [484](#)
- Elective neck dissection, for squamous cell carcinoma, [783](#)
- Electroacupuncture, for lichen simplex chronicus, [448](#)
- Electrocautery
 - for chondrodermatitis nodularis helices chronicus, [149](#)
 - for condyloma acuminata, [290](#)
 - for pyogenic granuloma, [716](#)
 - for syringoma, [814](#)
- Electrochemotherapy
 - for basal cell carcinoma, [564](#)
 - for nevoid basal cell carcinoma syndrome, [564](#)
- Electrocoagulation, for Fox-Fordyce disease, [285](#)
- Electrodesiccation
 - for atypical fibroxanthoma, [63–64](#)
 - for basal cell carcinoma, [80](#), [563](#)
 - for condyloma acuminata, [289](#)
 - for keratoacanthoma, [403](#)
 - for seborrheic keratosis, [775](#)
 - for syringomata, [815](#)
- Electrolysis
 - for Becker nevus, [85](#)

for hirsutism, [358–359](#)

Electromyographic biofeedback, for vulvodynia, [866](#)

Electron beam therapy

- for Darier disease, [180](#)
- for Hailey-Hailey disease, [317–318](#)
- for scleredema, [761–762](#)
- for scleromyxedema, [435](#)

Electron microscopy, for epidermolysis bullosa, [227](#)

Electrosurgery

- for condyloma acuminata, [290](#)
- for Darier disease, [179](#)
- for neurofibromatosis type 1, [560](#)
- for rhinophyma, [737](#)
- for syringomata, [814](#)
- for warts, [856](#)

Elephantiasis, [670](#)

Eliglustat tartrate, for Fabry disease, [269](#)

Elimination diet, for vulvodynia, [867](#)

ELISA

- for epidermolysis bullosa acquisita, [229](#)
- for leishmaniasis, [419](#)
- for pemphigoid gestationis, [663–664](#)

Embedded hair removal, for pseudofolliculitis barbae, [691](#)

EMLA

- for molluscum contagiosum, [509](#)
- for port wine stain, [655](#)

Emollients

- for atopic dermatitis, [54](#), [58](#)

for atopic eruption of pregnancy, [667](#)
for balanitis, [76](#)
for chronic actinic dermatitis, [154](#)
for discoid eczema, [206](#)
for erythroderma, [250](#)
for erythrodermic psoriasis, [705](#)
for erythrokeratodermas, [255](#)
for Grover disease, [834–835](#)
for ichthyosis, [365](#)
for intrahepatic cholestasis of pregnancy, [666](#)
for irritant contact dermatitis, [379](#)
for juvenile plantar dermatosis, [386](#)
for parapsoriasis, [598](#)
for pityriases rubra pilaris, [629](#)
for progressive symmetric erythrokeratoderma, [256](#)
for pruritus, [678](#)
for radiation dermatitis, [719](#)
for renal itch, [682](#)
for scabies, [757](#)
for scleroderma, [764](#)
for seborrheic eczema, [771](#)
side effects of, [379](#)
for staphylococcal scalded skin syndrome, [785](#)
for xerosis, [878–880](#)

Emotional support, for nevoid basal cell carcinoma syndrome, [562](#)

End-stage renal disease, xerosis and, [880](#)

Endemic treponemal diseases, [625](#)

Endemic typhus (murine typhus), [741](#)

Endermologie, for cellulite, [138](#)

Endobronchial ultrasound, for relapsing polychondritis, [734](#)

Endocarditis, Q fever, [742](#)

Endogenous dyshidrotic eczema, [319–321](#), [319f](#)

Endometrial cancer, in polycystic ovary syndrome, [641](#)

Endoscopy, for hereditary hemorrhagic telangiectasia, [330](#)

Endothrix infections, [816](#)

Enoxaparin, for vulvodynia, [866](#)

Enteroviruses, [851](#)

Environment, xeroderma pigmentosum and, [873–874](#)

Enzymatic debridement, for decubitus ulcers, [182](#)

Enzyme immunoassay, for syphilis, [811](#)

Enzyme replacement therapy

- for α_1 -antitrypsin deficiency panniculitis, [585](#)
- for Fabry disease, [268](#), [270](#)

Eosinophilia-myalgia syndrome, [216](#)

Eosinophilic fasciitis, [216–219](#), [216f](#)

- management strategy for, [216–219](#)

Epidemic typhus, [741](#)

Epidermal grafting, for vitiligo, [862](#)

Epidermal growth factor receptor (EGFR) inhibitors, for folliculitis, [278](#)

Epidermal growth factors, xerosis and, [879](#)

Epidermal melasma, [493](#)

Epidermal nevi, [220–223](#), [220f](#)

Epidermal nevus syndrome, [220–221](#)

Epidermal permeability barrier, in keratosis pilaris, [407](#)

Epidermodysplasia verruciformis, [224–225](#), [224f](#)

Epidermolysis bullosa, [226–228](#), [226f](#)
Epidermolysis bullosa acquisita, [229–232](#), [229f](#)
 congenital, [230](#)
Epidermolytic hyperkeratosis, [220–221](#)
Epidermolytic palmoplantar keratoderma of Vörner, [581](#)
Epidermophyton, dermatophytosis and, [820](#)
Epidermophyton floccosum, [820](#)
Epilation
 for dissecting cellulitis of scalp, [211](#)
 for folliculitis, [278](#)
 for hirsutism, [358–359](#)
Epiluminescence microscopy, for *Sarcoptes scabiei*, [758–760](#)
Epinephrine, for warts, [857](#)
Epistaxis, in hereditary hemorrhagic telangiectasia, [329–330](#)
Eponychial marsupialization, for paronychia, [602](#)
Epoxy allergy, in construction industry, [27](#)
Epsilon aminocaproic acid, for hereditary angioedema, [328](#)
Epstein-Barr virus, hydroa vacciniforme and, [348](#), [351–352](#)
Erbium:YAG laser
 for Becker nevus, [85](#)
 for calcinosis cutis, [126–127](#)
 for Darier disease, [180](#)
 for elastosis perforans serpiginosa, [618](#)
 for keratosis pilaris, [406t](#)
 for rhinophyma, [738](#)
 for sebaceous hyperplasia, [770](#)
 for seborrheic keratosis, [776](#)
 for syringomata, [814–815](#)

- for verrucous epidermal nevus, [222](#)
- for warts, [856](#)
- for xanthelasma palpebrarum, [871](#)
- for Zoon's balanitis, [78](#)
- Erlotinib, for keratoacanthoma, [404](#)
- Erosive pustular dermatosis, [233–234](#), [233f](#)
- Eruptive macular pigmentation, idiopathic, [238](#)
- Eruptive xanthomas, [870](#)
- Er:YAG laser, *See* [Erbium:YAG laser](#)
- Erysipelas, [139–142](#), [139f](#)
- Erythema, decubitus ulcer and, [182](#)
- Erythema annulare centrifugum, [235–237](#), [235f](#)
- Erythema dyschromicum perstans, [238](#), [238f](#), [659](#)
- Erythema elevatum diutinum, [239–241](#), [239f](#)
 - management strategy in, [239–241](#)
- Erythema induratum of Bazin, [584–585](#), [587](#)
- Erythema induratum of Whitfield, [584–585](#)
- Erythema infectiosum (fifth disease), [603](#)
- Erythema migrans borreliosis, Lyme disease and, [466](#)
- Erythema multiforme, [242–244](#), [242f](#)
 - oral, [243](#)
 - orf, [577](#)
- Erythema multiforme major, [243](#)
- Erythema nodosum, [245–247](#), [245f](#), [584](#)
- Erythema nodosum leprosum, [426–427](#)
- Erythrasma, [248–249](#), [248f](#)
- Erythroderma, [250–254](#), [250f](#)
 - cutaneous diseases in, [251t](#)

drug-induced, [251t](#)

Erythrodermic bullous pemphigoid, [251](#)

Erythrodermic chronic actinic dermatitis, for tacrolimus, [253](#)

Erythrodermic cutaneous T-cell lymphoma, diagnosing, [251–254](#)

Erythrodermic dermatomyositis, associated with gastric cancer, [251](#)

Erythrodermic psoriasis, [705–706](#)

Erythrokeratodermas, [255–257](#), [255f](#)

Erythrokeratodermia variabilis, [256](#)

Erythromelalgia, [258–260](#), [258f](#)

Erythromelalgia Association Survey, [259](#)

Erythromycin

- for acne keloidalis nuchae, [4](#)
- for acne vulgaris, [8](#)
- for actinomycosis, [22](#)
- for bacillary angiomatosis, [73](#)
- for blistering distal dactylitis, [108](#)
- for bullous congenital ichthyosiform erythroderma, [253](#)
- for cat scratch disease, [135](#)
- for chancroid, [144](#)
- for confluent and reticulated papillomatosis, [161](#)
- for erythema nodosum, [247](#)
- for erythrasma, [248–249](#)
- for granuloma inguinale, [309–310](#)
- for impetigo, [370–371](#)
- for linear IgA bullous dermatosis, [453](#)
- for lymphogranuloma venereum, [475–476](#)
- for miliaria rubra, [507](#)
- for *Mycobacterium kansasii* infection, [529](#)

- for paronychia, [602](#)
- for perioral dermatitis, [620](#)
- for pitted and ringed keratolysis, [626](#)
- for pityriasis lichenoides et varioliformis acuta, [635–636](#)
- for pityriasis rosea, [638–639](#)
- for psoriasis, [704](#)
- for rosacea, [745](#)
- for yaws, [625](#)

Erythroplasia of Queyrat, [114–115](#), [114f](#)

Erythropoietic protoporphyria, [261–264](#), [261f](#)

Erythropoietin

- for epidermolysis bullosa, [226](#)
- for porphyria cutanea tarda, [652](#)

Escitalopram, for psychogenic excoriation, [710](#)

Esophagogastroduodenoscopy, for gastrointestinal polyps, [621](#)

Essential pruritus vulvae, [688](#)

Esthetic laser, for elastosis perforans serpiginosa, [618](#)

Estrogen dermatitis, [71](#)

Estrogen-progesterone, for hereditary hemorrhagic telangiectasia, [331](#)

Estrogen therapy

- for autoimmune progesterone dermatitis, [70](#)
- for hereditary hemorrhagic telangiectasia, [331](#)

Etanercept

- for aphthous stomatitis, [52](#)
- for Behçet disease, [92](#)
- for bullous pemphigoid, [119](#)
- for dermatomyositis, [202](#)
- for diffuse scleroderma, [767](#)

for erythema annulare centrifugum, [235](#)
for erythema nodosum, [247](#)
for erythema nodosum leprosum, [428](#)
for erythrodermic psoriasis, [254](#)
for graft-*versus*-host disease, [299](#)
for granuloma annulare, [306](#)
for Grover disease, [835](#)
for Hailey-Hailey disease, [318](#)
in inducible urticaria, [376](#)
for inflammatory linear verrucous epidermal nevus, [223](#)
for leprosy reaction, [426](#)
for mucous membrane pemphigoid, [520](#)
for nail psoriasis, [545](#)
for necrobiosis lipoidica, [551](#)
for pityriases rubra pilaris, [630](#)
for pityriasis lichenoides chronica, [634](#)
for pompholyx, [321](#)
for psoriasis, [702](#)
 erythrodermic, [705](#)
 pustular, [706](#)
for pyoderma gangrenosum, [713](#)
for reactive arthritis, [728](#)
for relapsing polychondritis, [734](#)
for sarcoidosis, [752](#), [754](#)
for Sneddon-Wilkinson disease, [804](#)
for Sweet syndrome, [808](#)

Ethambutol

for erythema induratum of Bazin, [587](#)

- for *Mycobacterium ulcerans* infection, [529](#)
- for tuberculosis, [838–839](#)
- Ethosomes-based topical delivery system, [104](#)
- Ethylestrenol, for malignant atrophic papulosis, [482](#)
- Etidronate, for juvenile dermatomyositis, [125](#)
- Etoposide
 - for cytophagic histiocytic panniculitis, [588](#)
 - for Kaposi sarcoma, [393](#)
 - for Langerhans cell histiocytosis, [409](#)
- Etretinate
 - for aphthous stomatitis, [10016#s0160](#)
 - for confluent and reticulated papillomatosis, [164](#)
 - for erythrodermic psoriasis, [706](#)
 - for Grover disease, [835](#)
 - for lichen nitidus, [437](#)
 - for lichen planopilaris, [439](#)
 - for nevoid basal cell carcinoma syndrome, [566](#)
 - for porokeratosis, [647](#)
 - for pustular psoriasis, [706–707](#)
 - for reactive arthritis, [728](#)
 - for subcorneal pustular dermatosis, [802–803](#)
- Eumycetoma, [522–525](#), [522f](#)
- Evening primrose oil, for Raynaud's phenomenon, [725](#)
- Everolimus, for necrolytic migratory erythema, [556](#)
- Evidence-based therapy, for sarcoidosis, [753](#)
- Exanthematous drug eruptions, [214](#)
- Exanthematous pustulosis, acute generalized, [24–25](#), [24f](#)
- Excess hair, reduction of, in Becker nevus, [b85](#)

Excimer laser

- for alopecia areata, [33](#)
- for granuloma annulare, [303](#)
- for lichen planopilaris, [439–440](#)
- for lymphomatoid papulosis, [480](#)
- for mycosis fungoides, [535](#)
- for palmoplantar pustulosis, [583](#)
- for psoriasis, [697](#), [703](#)
- for striae, [794–795](#)
- for vitiligo, [861–862](#)

Excision, *See* [Surgery](#)

Exercise

- eruption induction, with miliaria, [506](#)
- for juvenile plantar dermatosis, [386](#)
- for lymphedema, [471](#)

Exfoliative dermatitis, *See* [Erythroderma](#)

Exfoliative toxin, in staphylococcal scalded skin syndrome, [785–786](#)

External beam radiation therapy, for dissecting cellulitis of scalp, [212](#)

Extracorporeal monocyte granulocytapheresis, for erythema nodosum, [247](#)

Extracorporeal photochemotherapy (photopheresis), [253](#)

- for eosinophilic fasciitis, [218](#)
- for epidermolysis bullosa acquisita, [229](#)
- for febrile ulceronecrotic Mucha-Habermann disease, [637](#)
- for graft-*versus*-host disease, [299](#)
- for mycosis fungoides, [535](#)
- for nephrogenic systemic fibrosis, [558](#)
- for pityriases rubra pilaris, [631](#)
- for scleredema, [763](#)

for scleromyxedema, [434](#)
Extramammary Paget disease, [265–267](#), [265f](#)
Eye(s), *See* [Ocular involvement](#)
Eye lubricants, for xeroderma pigmentosum, [875](#)
Eyelid reconstruction, for xanthomas, [871](#)
Ezetimibe, for alopecia areata, [33](#)

F

Fabry disease, [268–271](#), [268f](#)

Fabry Outcome Survey, [269–270](#)

Face

flushing of, [272](#)

granuloma faciale on, [307](#)

port wine stain on, [653](#)

psoriasis of, [697](#)

Facial massage, for rosacea, [744](#)

Facial swelling, rosacea and, [750](#)

Factitious dermatitis, [191](#)

Factor V Leiden mutation, livedoid vasculopathy, [461](#)

Famciclovir

for herpes genitalis, [333–335](#)

for herpes labialis, [337–339](#)

for herpes zoster, [340–341](#)

for varicella, [845](#)

Familial Becker's nevus, [84](#)

Familial cold autoinflammatory syndrome (FCAS), [165](#)

Familial erythromelalgia, [259](#)

Familial hypercholesterolemia, xanthomas and, [871](#)

Familial leiomyomas, [416](#)

Familial multiple leiomyomata, [416](#)

Familial reactive perforating collagenosis, [616–617](#)

Family, effect on, of xeroderma pigmentosum, [874](#)

Family history, of herpes zoster, [342](#)

Far infrared rays, for sporotrichosis, [779](#)

Farnesyl transferase inhibitors, for neurofibromatosis type 1, [559](#)

Fasciitis, eosinophilic, [216–219](#), [216f](#)

Fat necrosis of newborn, subcutaneous, [805–806](#), [805f](#)

Fatty acid infusion, for necrolytic migratory erythema, [556](#)

Fatty acid levels, reduced, in necrolytic acral erythema, [552](#)

Febrile ulceronecrotic Mucha-Habermann disease, [635–636](#)

Fecal incontinence, pruritus ani and, [686](#)

Fecal protoporphyrin excretion, in erythropoietic protoporphyria, [263](#)

Female hair restoration, for androgenetic alopecia, [39](#)

Ferritin, porphyria cutanea tarda and, [651](#)

Ferrochelatase-deficient protoporphyria patients, erythropoietic protoporphyria in, [263](#)

Ferrodepletion, for porphyria cutanea tarda, [650](#)

Ferrous fumarate, for erythropoietic protoporphyria, [263](#)

Ferrous sulfate, for erythropoietic protoporphyria, [263](#)

Fetal complications, in intrahepatic cholestasis of pregnancy, [665–666](#)

Fetal varicella syndrome, [844](#)

Fetus

- anomalies, due to rubella, [848](#)
- human parvovirus B19 infection in, [604](#)

Fexofenadine, for chronic urticaria, [841t](#)

Fibrinolytic treatment, for malignant atrophic papulosis, [482](#)

Fibroblast lysate, for vulvodynia, [866](#)

Fifth disease (erythema infectiosum), [603](#)

Filaggrin gene (*FLG*), ichthyosis and, [365](#)

Film dressing, on radiation dermatitis, [720](#)

Finasteride

- for androgenetic alopecia, [38–39](#)
- for hirsutism, [359](#), [642](#)

Fine-needle aspiration, for subcutaneous fat necrosis of newborn, [805–806](#)

Fish oil supplementation

for acanthosis nigricans, [3](#)

for Raynaud's phenomenon, [725](#)

Fish tank (swimming pool) granuloma, [526](#)

FK-506, for psoriasis, [704](#)

FloSeal, for rhinophyma, [738](#)

Flubendazole, for onchocerciasis, [573](#)

Flucloxacillin

for acne keloidalis nuchae, [4](#)

for cellulitis, [141](#)

for miliaria rubra, [506](#)

for staphylococcal scalded skin syndrome, [787](#)

Fluconazole

for blastomycosis, [106](#)

for coccidioidomycosis, [158–159](#)

for cryptococcosis, [168](#), [170](#)

for cutaneous candidiasis, [171](#)

for diaper dermatitis, [205](#)

for histoplasmosis, [347](#), [349](#)

for leishmaniasis, [420](#)

for onychomycosis, [823](#), [825](#)

for paracoccidioidomycosis, [593](#), [595–596](#)

for pityriasis versicolor, [827–828](#)

for sporotrichosis, [777](#), [779](#)

for tinea capitis, [816](#), [818](#)

for tinea corporis, [820](#)

for tinea cruris, [820](#)

- for tinea pedis, [820](#), [822](#)
- for yellow nail syndrome, [881–882](#)
- 5-flucytosine
 - for chromoblastomycosis, [152](#)
 - for cryptococcosis, [168](#)
- Fluid replacement
 - for Stevens-Johnson syndrome, [830](#)
 - for toxic epidermal necrolysis, [830](#)
- Fluindione, for livedoid vasculopathy, [461](#)
- Fluocinolone, for melasma, [493–495](#)
- Fluocinolone acetonide, for melasma, [660](#)
- Fluocinonide
 - for inflammatory linear verrucous epidermal nevus, [222–223](#)
 - for lichen nitidus, [436](#)
 - for pretibial myxedema, [669](#)
- Fluorescent treponemal antibody absorbed (FTA-ABS) test, for syphilis, [811](#)
- Fluorodeoxyglucose (FDG)-positron emission tomography (PET), for Merkel cell carcinoma, [496](#)
- Fluoroquinolones
 - for gonorrhea, [296](#)
 - for lymphogranuloma venereum, [475](#)
 - for *Mycobacterium ulcerans* infection, [528–529](#)
 - for rickettsial spotted fever, [741](#)
 - for rosacea, [750](#)
- 5-fluorouracil (5-FU)
 - for actinic keratoses, [15](#), [17](#)
 - for basal cell carcinoma, [82](#)
 - for Bowen's disease, [115](#)

- for extramammary Paget disease, [266](#)
- for Hailey-Hailey disease, [318](#)
- for keloids, [399](#)
- for keratoacanthoma, [403](#)
- for nail psoriasis, [546](#)
- for necrolytic migratory erythema, [556](#)
- for nevoid basal cell carcinoma syndrome, [564–565](#)
- for palmoplantar keratoderma, [579](#)
- for porokeratosis of Mibelli, [647](#)
- for psoriasis, [703](#)
- for sarcoidosis, [756](#)
- for squamous cell carcinoma, [781](#)
- for verrucous epidermal nevus, [222](#)
- for warts, [857](#)
- for xeroderma pigmentosum, [874](#), [876](#)

Fluoxetine

- for body dysmorphic disease, [112](#)
- for itch associated with hematologic disorders, [685](#)
- for psychogenic excoriation, [709–710](#)
- for Raynaud's phenomenon, [724](#)
- for trichotillomania, [837](#)

Flurandrenolide tape

- for lichen simplex chronicus, [448–449](#)
- for stoma care, [790](#)

Flushing, [272–274](#), [272f](#)

- of rosacea, [274](#), [749](#)

Flutamide, for hirsutism, [359](#), [642](#)

Fluticasone propionate

- for atopic dermatitis, [58–59](#)
- for relapsing polychondritis, [735](#)
- Fluvastatin, for antiphospholipid syndrome, [48](#)
- Fluvoxamine
 - for body dysmorphic disease, [112](#)
 - for psychogenic excoriation, [709–710](#)
- Folic acid antagonists, for pustular psoriasis, [707](#)
- Follicular cheilitis, in actinic prurigo, [19](#)
- Follicular lichen planus, [438](#)
- Follicular lymphomatoid papulosis, [478](#)
- Follicular mucinosis, [275–277](#), [275f](#)
- Follicular occlusion triad, [211](#)
- Follicular unit extraction (FUE), for androgenetic alopecia, [38](#)
- Folliculitis, [278–280](#), [278f](#)
 - stoma and, [790](#)
- Folliculitis decalvans, [281–283](#), [281f](#)
- Folliculitis nuchae scleroticans, [5](#)
- Folliculitis spinulosa decalvans, [408](#)
- Fonsecaea pedrosoi*, [150](#), [152](#)
- Food handlers, paronychia and, [601](#)
- Footwear, nonocclusive, juvenile plantar dermatosis in, [386](#)
- Formaldehyde
 - for hyperhidrosis, [354](#)
 - for pitted and ringed keratolysis, [626](#)
- Formalin
 - for pitted and ringed keratolysis, [626](#)
 - for warts, [856](#)
- Formic acid, for warts, [855](#)

Foscarnet

for herpes genitalis, [335](#)

for herpes labialis, [338](#)

for herpes zoster, [340](#)

for human herpesvirus 6, [849](#)

for varicella, [845](#)

Fox-Fordyce disease, [284–285](#), [284f](#)

Fractional bipolar radiofrequency energy, for acne vulgaris, [11](#)

Fractional laser therapy

for melasma, [495](#)

for primary cutaneous amyloidosis, [35](#)

for pseudoxanthoma elasticum, [696](#)

Fractional microneedling radiofrequency (FMR), for acne vulgaris, [11](#)

Fractional photothermolysis

for porokeratosis, [648](#)

for striae, [795](#)

Francisella tularensis, [98](#)

Freckles, [658](#)

Frequency-doubled Q-switch ND-YAG laser, for urticaria pigmentosa, [491](#)

Frequency-modulated electromagnetic neural stimulation, for scleredema, [763](#)

Fresh frozen plasma, for hereditary angioedema, [327](#)

Frontal fibrosing alopecia, [438](#)

Frozen section ‘jelly roll’ technique, for bullous congenital ichthyosiform erythroderma, [251](#)

Full-thickness grafting, for granuloma faciale, [308](#)

Fumaric acid ester(s)

for granuloma annulare, [305](#)

- for necrobiosis lipoidica, [551](#)
- for palmoplantar pustulosis, [583](#)
- for pityriasis rubra pilaris, [631](#)
- for psoriasis, [704](#)
- for sarcoidosis, [755](#)

Fungal infections (mycoses)

- in erythrasma, [248](#)
- in palmoplantar keratoderma, [579](#)
 - see also individual infections*

Furosemide, for subcutaneous fat necrosis of newborn, [805](#)

Furunculosis (boils), [286–287](#), [286f](#)

Fusidic acid

- for erythrasma, [248](#)
- for folliculitis decalvans, [282](#)
- for impetigo, [371](#)
- for ocular rosacea, [751](#)
- for pitted and ringed keratolysis, [626](#)
- for rosacea, [750](#)

G

Gabapentin

- for brachioradial pruritus, [679](#)
- for burning mouth syndrome, [122](#)
- for complex regional pain syndrome, [731–732](#)
- for erythromelalgia, [259](#)
- for Fabry disease, [270](#)
- for hot flashes, [273](#)
- for leiomyoma, [416](#)
- for lichen simplex chronicus, [448](#)
- for multiple piloleiomyoma-related pain, [417](#)
- for notalgia paresthetica, [569](#), [679](#)
- for postherpetic neuralgia, [341](#), [341t](#)
- for prurigo nodularis, [675](#)
- for vulvodynia, [865](#)

Gadolinium-containing contrast agents (GCCAs)

- contraindications to, [557](#)
- for nephrogenic systemic fibrosis, [557](#)

α -galactosidase A deficiency, Fabry disease and, [268](#)

Gall bladder, carcinoma of, scleredema and, [761](#)

Galvanic electrolysis, for hirsutism, [358–359](#)

Ganciclovir

- for erythema multiforme, [243](#)
- for HHV-6 encephalitis, [849](#)
- for Kaposi sarcoma, [393](#)

Gangosa, [624](#)

Ganoderma lucidum (reishi mushroom), [756](#)

Garlic gel, for alopecia areata, [33](#)

Gastric adenocarcinoma, acanthosis nigricans and, [1](#)

Gastrointestinal bleeding, in hereditary hemorrhagic telangiectasia, [331](#)

Gastrointestinal polyps, Peutz-Jeghers syndrome and, [621](#)

Gemcitabine

- for atypical fibroxanthoma, [65](#)
- for Kaposi sarcoma, [393](#)

Gene therapy, for epidermolysis bullosa, [228](#)

General anesthesia, for port wine stain, [655](#)

General nail care, for nail psoriasis, [543](#)

Generalized hyperhidrosis, [354](#)

Genetic testing

- for nevoid basal cell carcinoma syndrome, [562](#)
- for Peutz-Jeghers syndrome, [621](#)

Genetics

- of acanthosis nigricans, [2](#)
- of acrodermatitis enteropathica, [12–13](#)

Genital herpes (herpes genitalis), [333–336](#), [333f](#)

Genital leiomyoma, [416](#)

Genome analyses, for *Treponema pallidum*, [625](#)

Gentamicin

- for bacillary angiomatosis, [75](#)
- for gonorrhea, [297](#)
- for granuloma inguinale, [309–310](#)
- for hidradenitis suppurativa, [344](#)
- for pitted and ringed keratolysis, [626](#)
- for plague, [99](#)
- for tularemia, [98](#)

Gentian violet, for angular cheilitis, [45](#)

Geographic tongue, [291–292](#), [291f](#)

Germline mutations, detection of, in Peutz-Jeghers syndrome, [621–623](#)

Gianotti-Crosti syndrome, [293f](#), [603](#)

Giant orf, [577–578](#)

Giant seborrheic keratoses, [775](#)

GJB3 (Connexin 31) mutation, [256](#)

GJB4 (Connexin 30.3) mutation, [256](#)

GLA gene mutation, [269](#)

Glaucoma, port wine stain and, [653](#)

Gleevec, for diffuse cutaneous systemic sclerosis, [767](#)

Global peptide profiling, in cutaneous lupus erythematosus, [209](#)

Glossitis areata migrans, [291](#)

Glossodynia (burning mouth syndrome), [120–123](#), [120f](#)

Gloves, for irritant contact dermatitis, [379](#)

Glucagon cell adenomatosis, [555](#)

Glucagonoma, [554](#)

Glucocorticoids, *See* [Corticosteroids](#)

Glucose transporter-1 (GLUT-1), for hemangiomas, [323](#)

Glutaraldehyde

- for hyperhidrosis, [628](#)
- for pitted and ringed keratolysis, [626](#)
- for warts, [856–857](#)

Gluten-free diet

- for dermatitis herpetiformis, [193](#)
- for erythema elevatum diutinum, [241](#)
- for palmoplantar pustulosis, [583](#)

Gluten sensitivity, [583](#)

Glycerol

for ichthyosis, [366](#)

for xerosis, [880](#)

Glyceryl trinitrate

for leiomyoma, [416](#)

for Raynaud's phenomenon, [723](#)

Glycolic acid

for acanthosis nigricans, [2–3](#)

for acne vulgaris, [9–10](#)

for epidermodysplasia verruciformis, [225](#)

for melasma, [493](#)

for pseudofolliculitis barbae, [691](#), [693](#)

for striae, [794](#), [796](#)

for warts, [855](#)

Glycopyrrolate, for hyperhidrosis, [354](#), [356](#)

Glycopyrronium bromide, for hyperhidrosis, [354](#)

GnRH analogs

for hirsutism, [359](#)

for pruritus vulvae, [690](#)

Goeckerman regimen, for psoriasis, [701](#)

Gold earrings, lymphocytoma cutis reactions to, [473](#)

Gold therapy

for discoid eczema, [206](#)

for lupus erythematosus profundus, [586](#)

for nodular vasculitis, [587](#)

Golimumab

for nail psoriasis, [545–546](#)

for psoriasis, [704](#)

Gonadotropin-releasing hormone (GnRH) agonists, for autoimmune progesterone dermatitis, [70](#)

Gonococcal cervicitis, [295](#)

Gonococcal urethritis, [295](#)

Gonorrhea, [295–297](#), [295f](#)

- special considerations in, [297](#)
- treatment failure in, [297](#)

Gorlin syndrome, *See* [Nevoid basal cell carcinoma syndrome](#)

Gorlin-Goltz syndrome, *See* [Nevoid basal cell carcinoma syndrome](#)

Gottron's erythroderma congenitalis progressiva symmetrica, [257](#)

Gougerot-Carteaud syndrome, [161](#)

Graft-*versus*-host disease, [298–301](#), [298f](#)

- acute, [298](#)
- chronic, [300](#)

Graft *versus* lymphoma (GVL) effect, [537](#)

Graham-Little syndrome, [438](#)

Granisetron, for rosacea, [750](#)

Granulocyte and monocyte adsorption apheresis

- for Behçet disease, [93](#)
- for pyoderma gangrenosum, [713](#)

Granulocyte colony-stimulating factor

- for cellulitis, [141–142](#)
- for epidermolysis bullosa, [228](#)

Granulocyte macrophage-colony stimulating factor, for pyoderma gangrenosum, [714](#)

Granuloma annulare, [302–306](#), [302f](#)

- generalized, [304–306](#)
- localized, [302–304](#)

Granuloma faciale, [307–308](#), [307f](#)

Granuloma inguinale, [309–311](#), [309f](#)
Granulomatous cheilitis, [312–315](#), [312f](#)
Granulomatous pigmented purpuric dermatosis, [132](#)
Graves disease, pretibial myxedema and, [668](#)
Gray baby syndrome, [739](#)
Gray dermatosis, [659](#)
Grenz ray therapy
 for irritant contact dermatitis, [380](#)
 for lentigo maligna, [424](#)
 for psoriasis of scalp, [704](#)
Griseofulvin
 for eosinophilic fasciitis, [216](#)
 for tinea capitis, [816–818](#)
 for Wells syndrome, [868](#)
Grover disease (transient acantholytic dermatosis), [834–835](#), [834f](#)
Guttate psoriasis, [698](#)

H

H₁ antihistamines

- for angioedema, [843](#)
- for erythrokeratoderma, [255](#), [257](#)
- for mastocytoses, [489](#)
- for polymorphic eruption of pregnancy, [662](#)
- for urticaria, [841](#)

Habit reversal

- for lichen simplex chronicus, [448](#)
- for psychogenic excoriation, [708](#), [710](#)
- for trichotillomania, [836](#)

Haemophilus ducreyi, chancroid from, [144](#)

Hailey-Hailey disease (benign familial pemphigus), [316–318](#), [316f](#)

HAIR-AN (hyperandrogenism, insulin resistance, and acanthosis nigricans) syndrome, [2](#)

Hair clippers, for pseudofolliculitis barbae, [691](#)

Hair growth, disorders of, [407](#)

Hair removal

- Becker nevus and, [85](#)
- hirsutism and, [358–359](#)
- hypertrichosis and, [358–359](#)
- laser, [359](#)

Hair transplant surgery, for androgenetic alopecia, [38](#)

Halobetasol

- for lichen simplex chronicus, [449–450](#)
- for lymphomatoid papulosis, [479](#)

Halofuginone, for Kaposi sarcoma, [393](#)

Hamartomatous polyposis syndromes, [622](#)

Hand(s)

- allergic contact dermatitis in, [26](#)
- irritant contact dermatitis in, [378](#), [378f](#)

Hand, foot, and mouth disease, [851](#)

Hand and foot eczema, [319–321](#), [319f](#)

Hand mycetoma, [523–525](#)

Hansen disease (leprosy), [362](#), [426–428](#), [426f](#)

Hardening, [375](#), [643](#)

Harlequin ichthyosis, [368](#)

Head louse (*Pediculus capitis*), [606](#)

Heart therapy, *See* [Thermotherapy](#)

Heart transplant, varicella in, [845](#)

Heat treatment, for bed bug infestations, [591](#)

Heating, ozonation, and exposure to ultraviolet light (H-O-U) therapy, for Raynaud's syndrome, [725](#)

Helicase-primase inhibitor, for herpes genitalis, [336](#)

Helicobacter pylori

- eradication of, for Raynaud's phenomenon, [725](#)
- palmoplantar pustulosis and, [582](#)
- rosacea and, [747](#), [751](#)

Hemangiomas, [322–324](#), [322f](#)

Hematin, for erythropoietic protoporphyria, [263](#)

Hematologic disorders

- eosinophilic fasciitis with, [216](#)
- itch associated with, [684–685](#)

Hematologic malignancy, in juvenile xanthogranuloma, [389–390](#)

Hematological deficiencies, with aphthous stomatitis, [50](#)

Hematopoietic stem cell transplantation

for erythropoietic protoporphyria, [261](#)
for mycosis fungoides and Sezary syndrome, [537](#)
Heme-albumin, for erythropoietic protoporphyria, [263](#)
Hemochromatosis (HFE) gene mutations, in porphyria cutanea tarda, [651](#)
Hemodialysis
for calciphylaxis, [129](#)
for porphyria cutanea tarda, [650](#)
Hemorrhagic fevers, viral, [100](#)
Hemosiderin, for lipodermatosclerosis, [454](#)
Henoch-Schönlein purpura, [429](#)
Heparin
for antiphospholipid syndrome, [47](#)
for dermatitis herpetiformis, [193](#)
for livedoid vasculopathy, [461](#)
for malignant atrophic papulosis, [482](#)
for necrobiosis lipoidica, [550](#)
for Raynaud's phenomenon, [725](#)
Hepatitis B virus
in Gianotti-Crosti syndrome, [293](#)
granuloma annulare associated with, [306](#)
in lymphogranuloma venereum, [475](#)
Hepatitis C virus
in erythema multiforme, [244](#)
in intrahepatic cholestasis of pregnancy, [665](#)
in lichen planus, [441–443](#)
in lymphogranuloma venereum, [475](#)
in necrolytic acral erythema, [553](#)
in oral lichen planus, [574](#)

in porphyria cutanea tarda, [650](#)

Hepatitis panel tests, for necrolytic acral erythema, [552–553](#)

Hepatocellular carcinoma, porphyria cutanea tarda and, [650](#)

Hepatoerythropoietic porphyria, [650](#)

Herbal medicine, for aphthous stomatitis, [51](#)

Herbal preparations, for oral lichen planus, [574](#)

Hereditary angioedema, [325–328](#), [325f](#)

- acute, [325–327](#)
- dental and surgical interventions, relapse prevention of, [326](#), [328](#)
- long-term prophylaxis for, [325–328](#)

Hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome), [329–332](#), [329f](#)

Hereditary leiomyomatosis, renal cell cancer and, [416](#)

Herpangina, [851](#)

Herpes genitalis (genital herpes), [333–336](#), [333f](#)

- acute reactivation episodes of, [334](#)
- prevention of, [336](#)
- primary genital infection of, [334](#)
- prophylactic treatment of, [334–335](#)

Herpes gestationis, *See* [Pemphigoid gestationis](#)

Herpes labialis, [337–339](#), [337f](#)

- prophylactic treatment of, [b339](#)

Herpes simplex vaccine, for herpes genitalis, [336](#)

Herpes simplex virus (HSV) infection

- erythema multiforme and, [242](#)
- gingivostomatitis and, [338](#)
- herpes labialis and, [337](#)

Herpes simplex virus type 2 (HSV-2), in herpes genitalis, [333](#), [335–336](#)

Herpes zoster (shingles), [340–343](#), [340f](#)

Herpes zoster vaccine, [340](#), [342](#)

Hexachlorophene body wash, for MRSA, [501](#)

Hexanicotinate inositol (Hexopal), for Raynaud's disease, [724](#)

Hexyl nicotinate cream, for chilblains, [146](#)

HFE gene mutations, porphyria cutanea tarda and, [650](#)

Hidradenitis suppurativa, [344–346](#), [344f](#)

High-dose interleukin-2 (HD-IL-2), for melanoma, [484](#), [487](#)

Highly active antiretroviral therapy (HAART)

- for epidermodysplasia verruciformis, [225](#)
- for herpes genitalis, [335](#)
- for human parvovirus B19 infection, [604](#)
- for molluscum contagiosum, [508](#), [511](#)

Hirsutism, [358–361](#), [358f](#)

- polycystic ovary syndrome and, [640–642](#)

Histiocytoid Sweet syndrome, [809](#)

Histology

- of actinic keratoses, [14](#)
- of amyloidosis, [35](#)
- of atypical nevi, [68](#)
- of basal cell carcinoma, [79](#)
- of bed bugs, [89](#)
- of cytophagic histiocytic panniculitis, [585](#)
- of decubitus ulcer, [183](#)
- of discoid lupus erythematosus, [209](#)
- of eccrine sweat ducts, [505](#)
- of eosinophilic fasciitis, [216](#)
- of erythema dyschromicum perstans, [238](#)
- of erythema multiforme, [242](#)

- of erythroderma, [250](#)
- of granuloma annulare, [302](#)
- of granuloma faciale, [307](#)
- of idiopathic eruptive macular pigmentation, [238](#)
- of livedo reticularis, [457](#)
- of melanoma, [484](#)
- of necrolytic acral erythema in, [552](#)
- of notalgia paresthetica, [569–570](#)
- of pancreatic panniculitis, [585](#)
- of paracoccidioidomycosis, [594](#)
- of pityriases rubra pilaris, [629](#)
- of sebaceous hyperplasia, [769](#)
- of staphylococcal scalded skin syndrome, [785](#)

Histopathology, *See* [Histology](#)

Histoplasma capsulatum, [347](#)

Histoplasma capsulatum var. *capsulatum*, [347](#)

Histoplasma capsulatum var. *duboisii*, [347](#)

Histoplasmosis, [347–350](#), [347f](#)

HIV/AIDS

- in acquired epidermodysplasia verruciformis, [225](#)
- in aphthous stomatitis, [51](#)
- in bacillary angiomatosis, [73](#)
- in cat scratch disease, [135](#)
- in chancroid, [143](#)
- in chronic actinic dermatitis, [155](#)
- in cryptococcosis, [168–170](#)
- in disseminated cryptococcosis, [691–692](#)
- in disseminated histoplasmosis, [347–348](#)

- in erythema elevatum diutinum, [240](#)
- in erythroderma, [252](#)
- in folliculitis, [278](#)
- in granuloma annulare, [306](#)
- in granuloma inguinale, [311](#)
- in herpes genitalis, [335](#)
- in herpes labialis, [338](#)
- in *Histoplasma capsulatum* var. *duboisii* infections, [349](#)
- in histoplasmosis, [348](#)
- in human parvovirus B19 infection, [604](#)
- in Kaposi sarcoma, [391–394](#)
- in leprosy reactions, [426](#)
- in lymphogranuloma venereum, [475](#)
- in molluscum contagiosum, [511](#)
- in myiasis, [539](#)
- in paracoccidioidomycosis, [593–596](#)
- in pityriases rubra pilaris, [631](#)
- in pityriasis lichenoides chronica, [636–637](#)
- in prurigo nodularis, [672](#)
- in pruritus, [685](#)
 - xerosis, [878](#)
- in reactive arthritis, [726–728](#)
- in seborrheic eczema, [771](#)
- in syphilis, [810–813](#)
- HLA-DRB1*15:03, [230](#)
- HLA typing, for actinic prurigo, [18](#)
- Homeopathic treatment, for renal itch, [683–684](#)
- Homozygosity mapping, in acrodermatitis enteropathica, [12–13](#)

Hookworm-related cutaneous larva migrans, [175](#)

Hormone replacement therapy (HRT), for flushing, [273](#)

Hospitalization, atopic dermatitis causing, [57–62](#)

Hot flashes, [273](#)

Hot water immersion, for jelly-fish stings, [382](#)

HR (Paroven, Venoruton; O-(beta-hydroxyethyl)-rutosides), [455](#)

5-HT₃ receptor antagonist, for rosacea, [750](#)

Hughes syndrome, *See* [Antiphospholipid syndrome](#)

Human amnion/chorion membrane, for lower extremity repair, [415](#)

Human α -galactosidase, for Fabry disease, [271](#)

Human granulocytic ehrlichiosis, [743](#)

Human herpesvirus 6 (HHV-6), roseola and, [849](#)

Human herpesvirus 7 (HHV-7), roseola and, [849](#)

Human leukocyte antigen, drug eruptions and, [213](#)

Human monocytic ehrlichiosis, [743](#)

Human papilloma virus (HPV)

- condyloma acuminata and, [288](#)
- epidermodysplasia verruciformis and, [224](#)
- warts from, [852](#)

Human parvovirus B19 infection, [603](#)

- fetal infection, [604](#)
- in pityriasis lichenoides et varioliformis acuta, [635](#)

Humira, *See* [Adalimumab](#)

Hyaluronic acid, for radiation dermatitis, [720](#)

Hydroa vacciniforme, [351–353](#), [351f](#)

Hydrocodone, for postherpetic neuralgia, [341t](#)

Hydrocolloid dressings

- for granuloma annulare, [302](#)

- for lichen simplex chronicus, [448](#)
- for lupus erythematosus profundus, [586](#)
- for necrobiosis lipoidica, [549](#)
- for palmoplantar pustulosis, [583](#)
- for reactive arthritis, [727](#)

Hydrocortisone

- for alopecia areata, [30](#)
- for atopic dermatitis, [59](#)
- for diaper dermatitis, [203](#)
- for Gianotti-Crosti syndrome, [294](#)
- for jellyfish stings, [383](#)
- for perioral dermatitis, [619–620](#)
- for pruritus ani, [687](#)
- for reactive arthritis, [727](#)
- for rosacea, [746](#)
- for seborrheic eczema, [772–774](#)
- for vitiligo, [861](#)

Hydrogel dressing, for radiation dermatitis, [720](#)

Hydrogen peroxide, for hypertrichosis, [358](#)

Hydroquinone

- for jellyfish stings, [383](#)
- for melasma, [494](#), [660](#)

(S)-1-[hydroxy-2-(phosphonylmethoxy) propyl]-cytosine, *See* [Cidofovir](#)

3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, [559](#)

α -hydroxy acids (AHAs), for xerosis, [880](#)

Hydroxychloroquine

- for alopecia totalis, [33](#)

- for antiphospholipid syndrome, [47](#)
- for chronic actinic dermatitis, [157](#)
- for cutaneous lupus erythematosus, [210](#)
- for dermatomyositis, [200](#)
- for eosinophilic fasciitis, [216](#)
- for erythema nodosum, [246](#)
- for follicular mucinosis, [276](#)
- for granuloma annulare, [305](#)
- for granulomatous cheilitis, [312](#), [315](#)
- for hydroa vacciniforme, [353](#)
- for Jessner lymphocytic infiltrate, [385](#)
- for lichen nitidus, [437](#)
- for lichen planopilaris, [439](#)
- for lupus panniculitis, [586](#)
- for lupus pernio, [754](#)
- for lymphcytoma cutis, [473](#)
- for oral lichen planus, [574](#)
- for perniosis, [146](#)
- for polymorphic light eruption, [644](#)
- for porphyria cutanea tarda, [651](#)
- for Q fever, [742](#)
- for refractory cutaneous lupus erythematosus (CLE), [798](#)
- for sarcoidosis, [752–753](#)
- for scleredema, [763](#)
- for subacute cutaneous lupus erythematosus, [798](#)
- for systemic lupus erythematosus, [798](#)

Hydroxychloroquine-induced recalcitrant, for acute generalized exanthematous pustulosis, [25](#)

Hydroxyethylrutosides, for erythropoietic protoporphyria, [262–263](#)

Hydroxypropyl cellulose film former, for aphthous stomatitis, [51](#)

Hydroxyurea

for chronic actinic dermatitis, [156](#)

for granuloma annulare, [306](#)

for psoriasis, [703](#), [706](#)

Hydroxyzine

for autoimmune progesterone dermatitis, [71](#)

for eosinophilic fasciitis, [218](#)

for jellyfish stings, [383](#)

Hygiene

for balanitis, [76](#)

for herpes genitalis, [336](#)

for impetigo, [369](#)

Hymenoptera spp., sting of, [489](#)

Hyoscine hydrobromide, for leiomyoma, [416](#)

Hyperandrogenic women, with acanthosis nigricans, [2](#)

Hyperbaric oxygen therapy

for actinomycosis, [23](#)

for calciphylaxis, [129](#)

for cellulitis and erysipelas, [142](#)

for decubitus ulcers, [186](#)

for diabetic foot ulcers, [415](#)

for livedoid vasculopathy, [462](#)

for pyoderma gangrenosum, [714–715](#)

Hypercalcemia, in subcutaneous fat necrosis of newborn, [805–806](#)

Hyperhidrosis, [354f](#), [628](#)

idiopathic, [354](#)

juvenile plantar dermatosis and, [386](#)

pompholyx and, [320–321](#)

Hyperhomocysteinemia, in livedoid vasculopathy, [461](#)

Hyperinsulinemia, acanthosis nigricans and, [1](#)

Hyperlipidemia, xanthomas and, [870](#)

Hyperparathyroidism, in pruritus, [684](#)

Hyperpigmentation

- other disorders of, [658–661](#), [658f](#)
- reduction of, in Becker nevus, [b85](#)

Hyperplasia, pretibial myxedema with, [669](#)

Hypersensitivity, drug, [214](#)

Hyperthermia, for warts, [855](#)

Hyperthyroidism, pretibial myxedema and, [668](#)

Hypertonic saline

- for leishmaniasis, [420](#)
- for lymphangioma circumscriptum, [468](#)

Hypertrichosis, [358–361](#), [358f](#)

- reduction of, in Becker nevus, [b85](#)

Hypertriglyceridemia, eruptive xanthomas and, [870](#)

Hypnosis

- for discoid eczema, [208](#)
- for pruritus vulvae, [690](#)
- for psychogenic excoriation, [708](#), [710](#)
- for rosacea, [749–750](#)
- for vulvodynia, [867](#)

Hypochlorite, for MRSA, [287](#)

Hypomelanosis, postinflammatory, [362–363](#)

Hypopigmented disorders, [362–364](#), [362f](#)

Hypopigmenting agents, [660t](#)

Hypothyroidism, xerosis and, [878](#)

Hypoxic ischemic encephalopathy (HIE), [805–806](#)

I

Ibuprofen, for Jessner lymphocytic infiltrate, [385](#)

Icatibant, for hereditary angioedema, [327](#)

Ice chips, for flushing, [273](#)

Ice packs, for jellyfish stings, [382](#)

Ichthammol-impregnated bandages, for juvenile plantar dermatosis, [387](#)

Ichthyoses, [365–368](#), [365f](#)

 acquired, [365](#)

 inherited, [365](#), [366f](#)

Ichthyosiform erythroderma, bullous congenital, [253](#)

Ichthyosis vulgaris (IV), [365](#)

Idarubicin, for scleromyxedema, [435](#)

Idiopathic eruptive macular pigmentation, [238](#)

Idiopathic erythroderma, [251](#)

Idiopathic guttate hypomelanosis, [363](#)

Idoxuridine

 for herpes labialis, [337](#)

 for orf, [577–578](#)

Ileostomies, [790](#)

Iloprost

 for Raynaud's phenomenon, [723](#), [764](#)

 for systemic sclerosis, [765](#)

Imatinib

 for dermatofibrosarcoma protuberans, [195–197](#)

 for diffuse cutaneous systemic sclerosis, [767](#)

 for mastocytoses, [491](#)

- for melanoma, [488](#)
- for nephrogenic systemic fibrosis, [558](#)
- for plexiform neurofibromas, [560](#)
- for scleroderma, [764](#)

Imidazoles, for erythrasma, [248](#)

Imipenem

- for actinomycetomas, [524](#)
- for actinomycosis, [22](#)
- for cellulitis and erysipelas, [141](#)

Imiquimod

- for actinic keratoses, [15](#)
- for alopecia areata, [33](#)
- for angiolymphoid hyperplasia with eosinophilia, [42](#)
- for balanitis, [78](#)
- for basal cell carcinoma, [81](#)
- for Bowen's disease, [115](#)
- for condyloma acuminata, [289](#)
- for elastosis perforans serpiginosa, [618](#)
- for epidermodysplasia verruciformis, [225](#)
- for erythroplasia of Queyrat, [115](#)
- for extramammary Paget disease, [266–267](#)
- for granuloma annulare, [303](#)
- for hemangiomas, [324](#)
- for herpes genitalis, [335](#)
- for Kaposi sarcoma, [393](#)
- for keloids, [400](#)
- for keratoacanthoma, [403](#)
- for leishmaniasis, [418](#), [420](#)

for lentigo maligna, [424–425](#)
for lymphangioma circumscriptum, [469](#)
for lymphomatoid papulosis, [480](#)
for melanoma, [487](#)
for molluscum contagiosum, [508](#), [510](#)
for morphea, [514](#)
for mycosis fungoides, [535](#)
for nevoid basal cell carcinoma syndrome, [564](#)
for orf, [578](#)
for porokeratosis of Mibelli, [647](#)
for port wine stain, [657](#)
for pyoderma gangrenosum, [715](#)
for pyogenic granuloma, [717](#)
for squamous cell carcinoma, [781](#), [783](#)
for warts, [854–855](#)
for xeroderma pigmentosum, [874](#), [876](#)
for Zoon's balanitis, [78](#)

Immune reconstitution inflammatory syndrome

histoplasmosis and, [347](#)
pompholyx and, [319](#)
sporotrichosis and, [777–778](#)

Immunoabsorption, for epidermolysis bullosa acquisita, [232](#)

Immunocompromised individuals

acyclovir resistance in, [845](#)
bacillary angiomatosis in, [74](#)
Bartonella infections in, [73](#)
cat scratch disease in, [135](#)
cellulitis in, [139](#)

erysipelas in, [139](#)
herpes genitalis in, [333–335](#)
herpes labialis in, [337–338](#)
histoplasmosis in, [347](#), [350](#)
orf in, [578](#)
roseola in, [849](#)
varicella in, [844–845](#)

Immunodiffusion, for paracoccidioidomycosis, [594](#)

Immunofixation electrophoresis, for erythema elevatum diutinum, [239](#)

Immunofluorescence

for epidermolysis bullosa, [227](#)
for epidermolysis bullosa acquisita, [229](#)
for Jessner lymphocytic infiltrate, [384](#)
for lichen planopilaris, [438](#)
for linear IgA bullous dermatosis, [451](#)
for paraneoplastic pemphigus, [611](#)
for polymorphic eruption of pregnancy, [662](#)
for Rocky Mountain spotted fever, [740](#)

Immunoglobulin(s)

for enteroviruses, [851](#)
for erythema multiforme, [244](#)
for folliculitis decalvans, [282–283](#)
intravenous, *See* [Intravenous immunoglobulin](#)
for measles, [850](#)
for scleredema, [762–763](#)
for yellow nail syndrome, [882](#)

Immunoglobulin A (IgA)

for dermatitis herpetiformis, [193](#)

- for epidermolysis bullosa acquisita, [230](#)
- for linear IgA bullous dermatosis, [452](#)
- for pemphigus, [802](#)

Immunoglobulin E (IgE), for scabies, [758](#)

Immunoglobulin G (IgG)

- for epidermolysis bullosa acquisita, [229](#)
- for human parvovirus B19 infection, [603](#)
- for juvenile polyarticular arthritis, [605](#)
- for measles, [850](#)
- for pemphigus, [611](#)
- for roseola, [849](#)

Immunoglobulin M (IgM)

- for measles, [850](#)
- for rubella, [848–849](#)

Immunosuppression

- for eosinophilic fasciitis, [216](#)
- for hydroa vacciniforme, [351](#)
- for mucous membrane pemphigoid, [519](#)
- for oral lichen planus, [574](#)
- for sporotrichosis, [777](#)

Immunotherapy

- for alopecia areata, [29–30](#)
- tumor, for melanoma, [486](#)

Impaired glucose tolerance, polycystic ovary syndrome and, [640–641](#)

Impetigo, [369–371](#), [369f](#), [757](#)

Impetigo herpetiformis, [698–704](#)

Imvamune, for smallpox, [95–96](#)

Incision and drainage, for paronychia, [600](#)

Indigo naturalis, for psoriasis, [703](#)

Indirect fluorescent antibody test (IFAT), for *Coxiella burnetii*, [743](#)

Indocyanine green (ICG) lymphography, for lymphedema, [470–471](#)

Indomethacin

for erythema nodosum, [246](#)

for follicular mucinosis, [276](#)

for folliculitis, [279](#)

for Jessner lymphocytic infiltrate, [385](#)

for Sweet syndrome, [807](#)

for urticarial vasculitis, [430](#)

Inducible urticarias, [372](#), [372f](#)

Infants

atopic dermatitis in, [59–60](#)

epidermolysis bullosa acquisita in, [230](#)

malignant atrophic papulosis in, [482](#)

panniculitis in, [585](#)

See also [Neonates](#)

Infection

in erythema annulare centrifugum, [235](#)

in erythema multiforme, [242](#)

in erythema nodosum, [245](#)

in impetigo, [369](#)

in pityriasis lichenoides chronica, [632](#)

in pityriasis lichenoides et varioliformis acuta, [635](#)

in stoma care, [790](#), [791t](#)

see also individual infectious disease/agents

Inflammatory bowel disease

cutaneous polyarteritis nodosa and, [177](#)

epidermolysis bullosa acquisita and, 230

See also [Crohn's disease](#), [Ulcerative colitis](#)

Inflammatory/dysplastic epidermal nevi, 222–223

Inflammatory linear verrucous epidermal nevus (ILVEN), 220

Inflammatory rosacea, 744–748, 750

Inflammatory tinea capitis (kerion), 211–212

Infliximab

for Behçet disease, 92–93

for chronic actinic dermatitis, 157

for cutaneous polyarteritis nodosa, 178

for dissecting cellulitis of scalp, 212

for eosinophilic fasciitis, 216, 218

for erythema nodosum, 247

for erythema nodosum leprosum, 428

for erythrodermic psoriasis, 254

for folliculitis decalvans, 282

for graft-*versus*-host disease, 300

for granuloma annulare, 306

for granulomatous cheilitis, 312, 314

for hidradenitis suppurativa, 346

histoplasma and, 348

for Kawasaki disease, 397

for leprosy reaction, 426

for lupus pernio, 754

for malignant atrophic papulosis, 482–483

for morphea, 514

for mucous membrane pemphigoid, 521

for necrobiosis lipoidica, 550

- for necrotizing vasculitis, [432](#)
- for pityriases rubra pilaris, [630](#)
- for psoriasis, [702](#)
 - erythrodermic, [705](#)
 - pustular, [706](#)
- for pyoderma gangrenosum, [711](#), [713](#)
- for reactive arthritis, [728–729](#)
- for relapsing polychondritis, [735](#)
- for sarcoidosis, [752](#), [754](#)
- for scleroderma, [764](#)
- for subcorneal pustular dermatosis, [804](#)
- for tuberculosis, [839](#)

Influenza vaccination, Gianotti-Crosti syndrome and, [294](#)

Infrared light, for cellulite, [137](#)

Ingenol mebutate

- for actinic keratoses, [16–17](#)
- for basal cell carcinoma, [82](#), [565](#)
- for molluscum contagiosum, [511](#)
- for porokeratosis of Mibelli, [648](#)

Inherited ichthyoses, [251](#)

Injected triamcinolone, for myxoid cyst, [541](#)

Ink spot lentigo, [658](#)

Inosine pranobex (inosiplex)

- for alopecia areata, [32](#)
- for herpes labialis, [337](#), [339](#)

Inosiplex, for alopecia areata, [32](#)

Insect repellents, [104](#)

- for bed bugs, [592](#)

for rickettsial spotted fever, [739](#)

Insecticides

illnesses associated, [87–88](#)

resistance to, bed bugs, [87–88](#)

Insulin-like growth factor 1 antagonist, for pretibial myxedema, [670](#)

Insulin-lowering drugs, for hypertrichosis, [359](#)

Insulin resistance

with acanthosis nigricans, [2](#)

cutaneous marker of, [2](#)

polycystic ovary syndrome and, [640–641](#)

Insulin sensitizers

for hirsutism, [361](#)

for polycystic ovary syndrome, [642](#)

Intense pulse light (IPL)

for Fabry disease, [270](#)

for hypertrichosis, [359](#)

for keratosis pilaris, [406t](#)

for lymphangioma circumscriptum, [469](#)

for melasma, [495](#)

for Peutz-Jeghers syndrome, [621](#), [623](#)

for port wine stain, [656](#)

for pseudofolliculitis barbae, [691](#), [693](#)

for radiation dermatitis, [720](#)

for rosacea, [744](#), [748](#)

for sebaceous hyperplasia, [770](#)

for striae, [794–795](#)

Intensity-modulated radiation, for folliculitis decalvans, [282](#)

Intensive care, for miliaria crystallina, [506](#)

Interferon(s)

for mycosis fungoides, [535](#)

for orf, [577](#)

for squamous cell carcinoma, [781](#)

Interferon- α , [459](#)

for angiolymphoid hyperplasia with eosinophilia, [43](#)

for aphthous stomatitis, [52](#)

for basal cell carcinoma, [81](#)

for Behçet disease, [92](#)

for chronic actinic dermatitis, [157](#)

for condyloma acuminata, [290](#)

for epidermodysplasia verruciformis, [225](#)

for erythema multiforme, [244](#)

for extramammary Paget disease, [267](#)

for follicular mucinosis, [276](#)

for Kaposi sarcoma, [392](#)

for keloids, [399](#)

for keratoacanthoma, [403](#)

for lentigo maligna, [424](#)

for lymphocytoma cutis, [474](#)

for lymphomatoid papulosis, [480](#)

for malignant melanoma, [484](#)

for molluscum contagiosum, [511](#)

for necrolytic acral erythema, [553](#)

for necrolytic acral erythema, [553](#)

for plexiform neurofibromas, [561](#)

for porphyria cutanea tarda, [652](#)

for scleromyxedema, [433](#)

- for Sweet syndrome, [808](#)
- for urticaria pigmentosa, [491](#)
- for warts, [855](#)
- for Wells syndrome, [869](#)

Interferon beta-1a, for basal cell carcinoma, [81](#)

Interferon- γ

- for atopic dermatitis, [57](#), [62](#)
- for coccidioidomycosis, [160](#)
- for cryptococcosis, [170](#)
- for granuloma annulare, [303–304](#)
- for keloids, [400](#)
- for *Mycobacterium abscessus* infection, [531](#)

Interferon- γ release assays (IGRAs), for tuberculosis, [838](#)

Interleukin 1 receptor antagonist, for cytophagic histiocytic panniculitis, [589](#)

Interleukin-2

- for melanoma, [487](#)
- PEG, for basal cell carcinoma, [82](#)

Interleukin-5, for angiolymphoid hyperplasia with eosinophilia, [42](#)

Interleukin-12, for Kaposi sarcoma, [393](#)

Interleukin-36 γ (IL-1F9), for psoriasis, with erythroderma, [251](#)

Interstitial lung disease, in dermatomyositis, [199](#)

Intertriginous psoriasis, [697](#)

Intertriginous xanthomas, [870](#)

Intrahepatic cholestasis of pregnancy, [665](#)

Intralesional agents, for basal cell carcinoma, [564](#)

Intralesional insulated needles, for syringomas, [815](#)

Intralesional platelet-rich plasma, for lipodermatosclerosis, [456](#)

Intralesional sodium tetradecyl sulfate injection, for myxoid cyst, [542](#)

Intramuscular immunoglobulins

for folliculitis, [280](#)

for Kaposi sarcoma, [394](#)

Intraocular involvement, in juvenile xanthogranuloma, [389](#)

Intrauterine transfusion, for fetal human parvovirus B19 infection, [604](#)

Intravenous gamma globulin, for necrotizing vasculitis, [432](#)

Intravenous immunoglobulin (IVIG), [375](#)

for antiphospholipid syndrome, [47–48](#)

for bullous pemphigoid, [118](#)

for calcinosis cutis, [126](#)

for cutaneous polyarteritis nodosa, [178](#)

for dermatomyositis, [201](#)

for epidermolysis bullosa acquisita, [229](#)

for febrile ulceronecrotic Mucha-Habermann disease, [637](#)

for human parvovirus B19 infection, [603–604](#)

for Kawasaki disease, [396](#)

for leukocytoclastic vasculitis, [432](#)

for livedoid vasculopathy, [462](#)

for lupus panniculitis, [586](#)

for malignant atrophic papulosis, [483](#)

for mucous membrane pemphigoid, [519](#)

for necrobiosis lipoidica, [550](#)

for pemphigoid gestationis, [664](#)

for pemphigus, [614](#)

for pityriases rubra pilaris, [631](#)

for pompholyx, [319](#)

for pretibial myxedema, [668–670](#)

for prurigo nodularis, [675](#)

- for pyoderma gangrenosum, [713](#)
- for relapsing polychondritis, [734–735](#)
- for scleromyxedema, [433](#)
- for staphylococcal scalded skin syndrome, [787](#)
- for Stevens-Johnson syndrome, [831](#)
- for subacute cutaneous lupus erythematosus, [800](#)
- for subcorneal pustular dermatosis, [804](#)
- for Sweet syndrome, [808](#)
- for toxic epidermal necrolysis, [830](#)
- for transient aplastic crisis, [603–604](#)

Inverse psoriasis, [698](#)

Iontophoresis

- for hyperhidrosis, [354](#), [356](#)
- for pitted and ringed keratolysis, [626](#)

Ipilimumab, for malignant melanoma, [484](#), [487](#)

Ipsilateral breast hypoplasia, Becker's nevus with, [86](#)

Iron deficiency, in prurigo nodularis, [672](#)

Iron oxide, for erythropoietic protoporphyria, [261](#)

Iron therapy, for erythropoietic protoporphyria, [263](#)

Irritant, in diaper dermatitis, [203](#)

Irritant contact dermatitis, [378–380](#), [378f](#)

- stomas and, [791t](#)

Irritant folliculitis, [278](#)

Irukandji jellyfish (*Carukia barnesi*), [381](#)

Isavuconazole, for cryptococcosis and dimorphic mycoses, [107](#)

Ischemic limb, necrobiosis lipoidica of, [548](#)

Isolated limb infusion, for Merkel cell carcinoma, [498](#)

Isolated limb perfusion

for melanoma, [484](#), [488](#)

for Merkel cell carcinoma, [498](#)

Isoniazid

for erythema induratum of Bazin, [587](#)

for lichen nitidus, [437](#)

for *Mycobacterium ulcerans* infection, [529](#)

for tuberculosis, [838–839](#)

1-isopropyl-4-phenyl-7-methyl-2(IH), [385](#)

Isopropyl myristate, for pediculosis capitis, [608](#)

Isotretinoin, [290](#)

for acanthosis nigricans, [3](#)

for acne keloidalis nuchae, [5](#)

for acne vulgaris, [7–8](#)

for angiolymphoid hyperplasia with eosinophilia, [42](#)

for atrophoderma vermiculatum, [407](#)

for basal cell carcinoma, [81](#), [565–566](#)

for Behçet disease, [92](#)

for confluent and reticulated papillomatosis, [163](#)

for Darier disease, [179](#)

for dissecting cellulitis of scalp, [211–212](#)

for eosinophilic fasciitis, [218](#)

for epidermodysplasia verruciformis, [225](#)

for epidermolysis bullosa, [228](#)

for erythema dyschromicum perstans, [238](#), [238t](#)

for erythrokeratoderma variabilis, [257](#)

for follicular mucinosis, [276](#)

for folliculitis decalvans, [281–282](#)

for Fox-Fordyce disease, [284–285](#)

for granuloma annulare, [304](#)
for Grover disease, [835](#)
for ichthyoses, [365](#)
for Jessner lymphocytic infiltrate, [385](#)
for keratoacanthoma, [404](#)
for Kyrle disease, [617](#)
for lichen nitidus, [437](#)
for lichen planus, [441](#)
for miliaria profunda, [507](#)
for nevoid basal cell carcinoma syndrome, [566](#)
for palmoplantar keratoderma, [580](#)
for perioral dermatitis, [620](#)
for porokeratosis, [647](#)
for prurigo pigmentosa, [677](#)
for pseudofolliculitis barbae, [788](#)
for psychiatric disorders, [8](#)
for pustular psoriasis, [706–707](#)
for pyoderma gangrenosum, [715](#)
for rhinophyma, [738](#)
for rosacea, [746](#)
for rosacea fulminans, [751](#)
for rosacea lymphedema, [750](#)
for sarcoidosis, [752](#), [754](#)
for scleromyxedema, [434](#)
for sebaceous hyperplasia, [769](#)
for squamous cell carcinoma, [784](#)
for steatocystoma multiplex, [788](#)
for subacute cutaneous lupus erythematosus, [800](#)

for ulerythema ophryogenes, [408](#)

for warts, [858](#)

for xeroderma pigmentosum, [874–876](#)

Itch-scratch cycle, of lichen simplex chronicus, [448](#)

Itraconazole

for blastomycosis, [105–106](#)

for central nervous system histoplasmosis, [350](#)

for chromoblastomycosis, [151–152](#)

for coccidioidomycosis, [159](#)

for cryptococcosis, [170](#)

for eumycetoma, [523](#)

for histoplasmosis, [347–348](#)

disseminated, [349](#)

pulmonary, [350](#)

for leishmaniasis, [420](#)

for lichen nitidus, [437](#)

for onychomycosis, [823](#)

for paracoccidioidomycosis, [593](#), [596](#)

for paronychia, [601](#)

for pityriasis versicolor, [827–828](#)

for *Pityrosporum* folliculitis, [279](#)

for seborrheic eczema, [771–772](#)

for sporotrichosis, [777–778](#)

for tinea capitis, [816–818](#)

for tinea pedis, [820](#), [822](#)

for yellow nail syndrome, [881](#)

Ivermectin

for bed bugs, [89](#)

for cutaneous larva migrans, [175](#)

for folliculitis, [279](#)

for myiasis, [539](#)

for onchocerciasis, [572–573](#)

for pediculosis capitis, [607](#)

pediculosis corporis, [609](#)

phthiriasis palpebrarum, [610](#)

for rosacea, [744–745](#), [747](#)

for scabies, [758–759](#)

Ixekizumab

for nail psoriasis, [545](#)

for psoriasis, [702–703](#)

Ixodes scapularis tick, [464](#)

J

Janus kinase inhibitors, for psoriasis, [698](#)

Jarisch-Herxheimer reaction, [811](#)

Jellyfish sting, [381–383](#), [381f](#)

Jessner lymphocytic infiltrate, [384–385](#), [384f](#)

Jessner's solution

for actinic keratoses, [17](#)

for melasma, [494](#), [661](#)

Juvenile acanthosis nigricans, [2](#)

Juvenile dermatomyositis, [201](#)

calcinosis cutis with, [124](#)

Juvenile myelomonocytic leukemia (JMML), [388–389](#)

Juvenile plantar dermatosis (atopic winter feet), [386–387](#), [386f](#)

Juvenile xanthogranuloma (JXG), [388–390](#), [388f](#)

K

- Kallikrein inhibitor, for hereditary angioedema, [325](#)
- Kanuka honey, for rosacea, [748](#)
- Kaposi sarcoma, [391–394](#), [391f](#)
- Kappa opioid receptor agonists, for pruritus, [685](#)
- Kawasaki disease, [395–397](#), [395f](#)
- Keloid fillet flap, [399](#)
- Keloids, [398–401](#), [398f](#)
- Keratin gel, for epidermolysis bullosa, [227](#)
- Keratitis, in erythema elevatum diutinum, [240](#)
- Keratoacanthoma, [402–404](#), [402f](#), [783](#)
 - multiple, [403–404](#)
 - solitary, [402–403](#)
- Keratocystic odontogenic tumors, in nevoid basal cell carcinoma syndrome, [565](#)
- Keratoderma, palmoplantar, [579–581](#), [579f](#)
- Keratolytics
 - for erythrokeratoderma, [255](#), [257](#)
 - for ichthyosis, [365](#)
 - for palmoplantar keratoderma, [579](#)
 - for warts, [852](#)
- Keratosis, seborrheic, [775–776](#), [775f](#)
- Keratosis pilaris (KP), [405–408](#), [405f](#)
- Keratosis pilaris atrophicans (KPA), [405](#)
- Keratosis pilaris decalvans nonatrophicans, [407](#)
- Keratosis rubra pilaris (KRP), [408](#)
- Kerion, [818](#)

Kerion celsi, [818](#)

Ketamine, for erythromelalgia, [260](#)

Ketoconazole

for blastomycosis, [106](#), [349](#)

for *Candida*, [171](#)

for coccidioidomycosis, [159](#)

for eumycetoma, [524](#)

for histoplasmosis, [347](#), [349](#)

for leishmaniasis, [420](#)

for lichen planopilaris, [439](#)

for paracoccidioidomycosis, [593](#), [595](#)

for pityriasis versicolor, [827–828](#)

for seborrheic eczema, [771–774](#)

for sporotrichosis, [777](#)

for subcorneal pustular dermatosis, [804](#)

for tinea capitis, [816](#), [818–819](#)

for tinea pedis, [820–822](#)

Ketotifen

for eosinophilic fasciitis, [216](#)

for neurofibromas, [559–560](#)

Kidney transplant, Fabry disease and, [271](#)

Kilovoltage photons, for rhinophyma, [738](#)

Kimura disease, [41](#)

Kineret, *See* [Anakinra](#)

KIT gene, in melanoma, [488](#)

Klebsiella granulomatis, [309](#)

Koebner phenomenon

in nail psoriasis, [543](#)

- in perforating dermatoses, [616](#)
- in pyoderma gangrenosum, [711](#)
- Kojic acid, for melasma, [494](#)
- Koplik spots, [849–850](#)
- KTP laser
 - for Fabry disease, [270](#)
 - for granuloma faciale, [308](#)
 - for keratosis pilaris, [406t](#)
 - for port wine stain, [657](#)
 - for pyogenic granuloma, [716–717](#)
 - for xanthomas, [871](#)
- Kyrle disease, [616–618](#)
- Kytococcus sedentarius*, [627](#)

L

β -lactam, for MRSA, [501](#)

Lactate, for xerosis, [879](#)

Lactic acid

for erythrokeratodermas, [255](#)

for molluscum contagiosum, [510](#)

for palmoplantar keratoderma, [579](#)

for warts, [852](#), [854–855](#)

for xerosis, [878](#)

Lamotrigine, for vulvodynia, [865](#)

Langerhans cell histiocytosis, [409–413](#), [409f](#)

Langerhans cells, [409](#)

Lanolin

for miliaria profunda, [507](#)

for xerosis, [879](#)

Lanreotide

carcinoid treated with, [274](#)

for necrolytic migratory erythema, [554–555](#)

Lansoprazole, for malignant atrophic papulosis, [482](#)

Large cell transformation, mimicking lymphomatoid papulosis, [479](#)

Large plaque parapsoriasis, [598–599](#)

Laryngeal chondritis, [733](#)

Laser treatment

for acne vulgaris, [10](#)

for actinic keratoses, [17](#)

for alopecia areata, [32–33](#)

for angiolymphoid hyperplasia with eosinophilia, [42](#)

- for aphthous stomatitis, [52](#)
- for Becker nevus, [85](#)
- for cellulite, [137](#)
- for dissecting cellulitis of scalp, [211](#)
- for granuloma faciale, [308](#)
- for hypopigmented disorders, [363](#)
- for lipodermatosclerosis, [455](#)
- for lymphedema, [471](#)
- for macular amyloidosis patches, [35](#)
- for male and female pattern hair loss, [39–40](#)
- for melasma, [493](#)
- for mucous membrane pemphigoid, [521](#)
- for onychomycosis, [825](#)
- for oral lichen planus, [576](#)
- for port wine stain, [654](#)
- for pseudofolliculitis barbae, [691](#), [693–694](#)
- for pyogenic granuloma, [716–717](#)
- for Raynaud's phenomenon, [725](#)
- for sebaceous hyperplasia, [769–770](#)
- for steatocystoma multiplex, [789](#)
- for striae, [795](#)
- for verrucous epidermal nevus, [221–222](#)

Lassa fever, [101](#)

Latanoprost, for alopecia areata, [31](#)

Latent syphilis, [811](#)

Lavender oil

- for cutaneous candidiasis, [172](#)
- for pediculosis capitis, [608](#)

LDE225 (sonidegib) cream, for nevoid basal cell carcinoma syndrome, [565](#)

LED photoprevention, for polymorphic light eruption, [645](#)

Leeches

for lymphocytoma cutis, [473](#)

paronychia for, [602](#)

Leflunomide

for morphea, [514](#)

for nail psoriasis, [547](#)

for psoriasis, [704](#)

for relapsing polychondritis, [734](#)

for sarcoidosis, [752](#), [755–756](#)

Leflunomide, for keratoacanthoma, [404](#)

Leg ulcers, [414–415](#), [414f](#)

Leiomyoma, [416–417](#), [416f](#)

Leishmaniasis, [418–421](#), [418f](#)

Lenalidomide

for Behçet disease, [92](#)

for cutaneous lupus erythematosus, [210](#), [799–800](#)

for Kaposi sarcoma, [393](#)

for prurigo nodularis, [675](#)

for Sweet syndrome, [809](#)

Lentigines, [658](#)

Lentiginosis syndromes, [658](#)

Lentigo maligna (LM), [422–425](#), [422f](#)

Lentigo maligna melanoma, [422–424](#)

Lentigo simplex, [658](#)

Lepromatous leprosy, [426](#)

Leprosy (Hansen disease), [362](#), [426–428](#), [426f](#)

Leprosy reactions, [426–428](#), [426f](#)

Leukemia inhibitory factor, for eosinophilic fasciitis, [217](#)

Leukocytopheresis, for pyoderma gangrenosum, [713](#)

Leukocytoclastic vasculitis, [429–432](#), [429f](#)

Leukotriene-receptor inhibition, for mastocytoses, [491](#)

Leuprorelin

- for extramammary Paget disease, [267](#)
- for pruritus vulvae, [690](#)

Levamisole

- for lichen nitidus, [437](#)
- for oral lichen planus, [576](#)
- for pediculosis capitis, [608](#)

Levaquin, for leprosy, [426](#)

Levocetirizine

- for chronic urticaria, [841t](#)
- for mosquito bite reactions, [592](#)

Levofloxacin

- for actinomycosis, [23](#)
- for *Mycobacterium fortuitum* infection, [530](#), [530t](#)

Lichen myxedematosus, [433–435](#), [433f](#)

Lichen nitidus, [436–437](#), [436f](#)

Lichen planopilaris, [438–440](#), [438f](#)

Lichen planus, [441–444](#), [441f](#)

- oral, [574–576](#), [574f](#)

Lichen planus pigmentosus, [659](#)

Lichen sclerosus, [76](#), [362](#), [445–447](#), [445f](#)

Lichen simplex chronicus (neurodermatitis circumscripta), [448–450](#), [448f](#)

Lichenoid drug eruptions, [442](#)

Lidocaine

- for cholestatic pruritus, [680](#)
- for complex regional pain syndrome, [732](#)
- for erythromelalgia, [258–259](#)
- for molluscum contagiosum, [509](#)
- for notalgia paresthetica, [569](#)
- for postherpetic neuralgia, [340](#), [342](#)
- for prurigo nodularis, [674](#)
- for rosacea, [748](#)
- for vulvodynia, [864–865](#), [867](#)
- for warts, [857](#)

Lifestyle changes, in polycystic ovary syndrome, [641](#)

Ligation, of pyogenic granuloma, [717](#)

Light therapy, low-level, for herpes labialis, [338–339](#)

Limited cutaneous systemic sclerosis, [764](#)

Lindane

- for pediculosis capitis, [608](#)
- for scabies, [757](#), [760](#)
- toxicity, [608](#)

Linear focal elastosis, for striae, [794](#)

Linear IgA bullous dermatosis, [451–453](#), [451f](#)

Linear nevus sebaceus, treatment for, [568](#)

Linezolid

- for cellulitis and erysipelas, [141](#)
- for MRSA, [287](#), [502](#)
- for mycetoma, [525](#)

Lip, in actinic prurigo, [19](#)

Lipodermatosclerosis (sclerosing panniculitis), [454–456](#), [454f](#), [585](#)

Lipoprotein apheresis, for scleredema, [763](#)

Liposomal DNA-repair enzymes, for polymorphic light eruption, [645](#)

Liposomal tretinoin, for Kaposi sarcoma, [393](#)

Liposuction

- for Fox-Fordyce disease, [285](#)
- for hyperhidrosis, [356](#)

5-Lipoxygenase inhibitor, for acne vulgaris, [9](#)

Liquid nitrogen

- cryosurgery/cryotherapy, *See* [Cryosurgery/cryotherapy](#)
- for postherpetic neuralgia, [342](#)

Liquor carbonis detergens, for psoriasis, [699](#)

Listeria monocytogenes-based vaccine, [104](#)

Listerine, for aphthous stomatitis, [50](#)

Lithium

- for seborrheic eczema, [771–772](#)
- xerosis from, [879](#)

Lithotripsy, extracorporeal shock wave, for calcinosis cutis, [127](#)

Livedo reticularis, [457–459](#), [457f](#)

Livedoid vasculopathy (vasculitis), [460–463](#), [460f](#)

Liver biopsy, for porphyria cutanea tarda, [650](#)

Liver disease

- in erythropoietic protoporphyria, [263](#)
- in hereditary hemorrhagic telangiectasia, [330](#)

Liver function tests

- for Gianotti-Crosti syndrome, [293](#)
- for necrolytic acral erythema, [552–553](#)

Liver spots, [775](#)

Liver transplantation

for erythropoietic protoporphyria, [263–264](#)
for necrolytic acral erythema, [553](#)
for necrolytic migratory erythema, [556](#)
Loa loa, [573](#)
Lobular capillary hemangioma, [716–718](#), [716f](#)
Lobular panniculitis, [584](#)
Lobules, [584](#)
Local anesthesia, for syringomata, [814](#)
Local granulocyte-macrophage colony-stimulating factor, for
necrobiosis lipoidica, [551](#)
Localized hyperhidrosis, [354](#)
Localized Scleroderma Cutaneous Assessment Tool (LoSCAT), for
morphea, [513](#)
Locoregional cutaneous metastases, of malignant melanoma, [487](#)
Loiasis, onchocerciasis and, [571](#)
Long-pulsed 1064-nm neodymium:yttrium-aluminum-garnet laser
(LPND), for rosacea, [748](#)
Long-pulsed dye laser, for radiation dermatitis, [720](#)
Loratadine
 for chronic urticaria, [841t](#)
 for mosquito-bite allergy, [592](#)
Losartan
 for Raynaud's phenomenon, [724](#), [766](#)
 for scleroderma, [766](#)
 for systemic sclerosis, [766](#)
LouseBuster, for pediculosis capitis, [609](#)
Lovastatin, for neurofibromatosis type 1, [561](#)
Low-calcium dialysis, for calciphylaxis, [129](#)
Low-calcium diet, for subcutaneous fat necrosis of newborn, [805](#)

Low-cobalt diet, for dyshidrotic eczema, [320](#)

Low-level light therapy, for herpes labialis, [337–339](#)

Lucilia cuprina, myiasis and, [538–540](#)

Lucio phenomenon, [426](#)

“Lucky Luke” dermatitis, [203–204](#)

Luliconazole, for tinea pedis, [821](#)

Lupus panniculitis, [584](#), [586–587](#)

Lupus pernio, [753–754](#)

Lupus profundus (lupus panniculitis), [584](#)

Lupus vulgaris, [838–839](#)

Lycopene, for oral lichen planus, [574](#), [576](#)

Lyme arthritis, [465](#)

Lyme borreliosis (Lyme disease), [464–466](#), [464f](#)

- early disseminated, [464–465](#)
- early localized, [464](#)
- late, [465](#)
- prevention, [465](#)
- prophylaxis, [465](#)
- reinfection, [465](#)
- testing, [465](#)

Lymecycline, for rosacea, [745](#)

Lymphadenectomy, for malignant melanoma, [484](#), [488](#)

Lymphadenopathy, paracoccidioidomycosis and, [593](#)

Lymphangioma circumscriptum, [467–469](#), [467f](#)

- management strategies for, [467–469](#)

Lymphatic filariasis, [573](#)

Lymphedema, [470–471](#), [470f](#)

- yellow nail syndrome and, [882](#)

Lymphedema praecox, [470](#)

Lymphedema tarda, [470](#)

Lymphocyte transformation test, [214](#)

Lymphocytoma cutis, [472–474](#), [472f](#)

Lymphogranuloma venereum, [475–476](#), [475f](#)
management strategy for, [475–476](#)

Lymphoma(s)
cutaneous, classification of, [477](#)
cutaneous T-cell, [532](#)
follicular mucinosis associated with, [275](#)

Lymphomatoid papulosis, [477–480](#), [477f](#)
angioinvasive, [478](#)
follicular, [478](#)
type D, [478](#)
variants of, [477–478](#)

Lymphoscintigraphy, for lymphedema, [470](#)

LyP, *See* [Lymphomatoid papulosis](#)

M

Macrolides

for rosacea, [750](#)

Treponema pallidum, resistance to, [813](#)

Madurella mycetomatis, [522](#)

Maggot therapy, for calciphylaxis, [130](#)

Magnesium, for erythromelalgia, [260](#)

Magnetic resonance imaging (MRI), *See* [MRI](#)

Major box jellyfish (*Chironex fleckeri*), [381](#)

Malaria, [104](#)

Malassezia, [827](#)

seborrheic eczema and, [771](#)

Malathion

for pediculosis capitis, [606](#)

resistant, [607](#)

for pediculosis corporis, [609](#)

for scabies, [590](#), [758–759](#)

Malignant atrophic papulosis, [481–483](#), [481f](#)

Malignant fibrous histiocytoma (MFH), [63](#)

Malignant melanoma, [84](#)

Malignant peripheral nerve sheath tumors (MPNSTs), [559–560](#)

Malignant transformation, of oral lichen planus, [574](#)

Malnutrition, epidermolysis bullosa and, [226](#)

Manual extrusion, for molluscum contagiosum, [508](#)

Manual lymphatic drainage, for yellow nail syndrome, [882](#)

Marsupialization

in mucoceles, [516](#)

- for paronychia, [602](#)
- Masitinib, for mastocytoses, [491–492](#)
- Mass treatment programs, for onchocerciasis, [571–573](#)
- Mast cell proliferation, in mastocytoses, [489](#)
- Mastocytoses, [489–492](#), [489f](#)
- Matrix metalloproteinase inhibitor COL-3, for Kaposi sarcoma, [393](#)
- Matrix steroid injections, for yellow nail syndrome, [881](#)
- Maxacalcitol, for subcorneal pustular dermatosis, [804](#)
- Measles, mumps, rubella and varicella vaccine
 - for measles, [850](#)
 - for rubella, [848](#)
 - for varicella prophylaxis, [846](#)
 - for warts, [854](#)
- Measles (rubeola), [849](#)
- Measles vaccine, [850](#)
- Mebhydrolin, for subcorneal pustular dermatosis, [804](#)
- Mechlorethamine
 - for large plaque parapsoriasis, [599](#)
 - for lymphomatoid papulosis, [479](#)
- Medical alert bracelets, [874](#)
- Medical honey, for MRSA, [503](#)
- Medium chain fatty acid triglyceride supplements, for yellow nail syndrome, [881](#)
- Medium vessel vasculitides, [429](#)
- Megasession technique, for neurofibromatosis type 1, [560](#)
- Meglumine antimoniate, [418–421](#)
- Meibomian gland dysfunction, [750–751](#)
- Meige disease, [470](#)
- MEK inhibition, in melanoma, [484–485](#), [488](#)

MelaFind, for malignant melanoma, [484](#), [486](#)
Melaleuca alternifolia, [510–511](#)
Melaleuca oil, for pediculosis capitis, [608](#)
Melanocortin, [658](#)
Melanocyte autologous grafting, for leukoderma, [364](#)
Melanocytic lesions, in atypical nevi, [67](#)
Melanoma
 delayed detection of, [67](#)
 guidance in, [68](#)
 malignant, [484–488](#), [484f](#)
 locoregional cutaneous metastases of, [487](#)
 prevention of, [484](#)
 staging and classification, [485–488](#)
 number of nevi excised per, [67](#)
Melanosis
 periorbital, [659](#)
 Riehl, [659](#)
Melanosome transfer, inhibition of, [660t](#)
Melasma, [493–495](#), [493f](#), [658–659](#)
Melatonin, for sarcoidosis, [755](#)
Melittin, for MRSA, [503](#)
Melkersson-Rosenthal syndrome, [312–313](#)
Melphalan
 for pretibial myxedema, [670](#)
 for scleredema, [763](#)
 for scleromyxedema, [433](#)
Ménière disease, cutaneous mastocytosis and, [492](#)
Menopause-associated vasomotor symptoms, [274](#)

Menthol, for pruritus ani, [687](#)

Mepacrine

for follicular mucinosis, [275](#)

for sarcoidosis, [755](#)

Mepilex, for epidermolysis bullosa, [226](#)

Mercaptopurine, for pyoderma gangrenosum, [714](#)

6-mercaptopurine, for Langerhans cell histiocytosis, [411](#)

Merkel cell carcinoma, [496–498](#), [496f](#)

management strategy for, [496–498](#)

Metabolic disorders, of prurigo nodularis, [673](#)

Metabolic syndrome, polycystic ovary syndrome and, [640–641](#)

Metal salt, challenge with, discoid eczema, [207](#)

Metastasectomy, for pancreatic panniculitis, [588](#)

Metastatic calcification, subcutaneous fat necrosis of newborn and, [806](#)

Metastatic disease, of extramammary Paget disease, [266](#)

Metformin

for acanthosis nigricans, [2](#)

for hidradenitis suppurativa, [345](#)

for polycystic ovary syndrome, [640](#), [642](#)

Methenamine gel, for hyperhidrosis, [354](#)

Methicillin-resistant *Staphylococcus aureus* (MRSA), [499–504](#), [499f](#), [786](#)

decolonization regimens for, [499](#)

in folliculitis, [278](#)

in furunculosis, [286](#)

in impetigo, [369](#), [371](#)

nasal carriage in, [500](#)

purulent material in, [499](#)

specific investigations for, [499–503](#)

Methionine, for warts, [858](#)

Methotrexate

for allergic contact dermatitis, [28](#)

for alopecia areata, [32](#)

for atopic dermatitis, [56–57](#), [62](#)

for Behçet disease, [90](#)

for bullous pemphigoid, [118](#)

for capillaritis, [133](#)

for cutaneous polyarteritis nodosa, [178](#)

for dermatomyositis, [200](#)

for diffuse cutaneous systemic sclerosis, [765](#)

for discoid eczema, [208](#)

for eosinophilic fasciitis, [216](#)

for febrile ulceronecrotic Mucha-Habermann disease, [636](#)

for graft-*versus*-host disease, [299](#)

for granuloma annulare, [305](#)

for Hailey-Hailey disease, [318](#)

for Jessner lymphocytic infiltrate, [385](#)

for juvenile xanthogranuloma, [390](#)

for keratoacanthoma, [403](#)

for Langerhans cell histiocytosis, [409](#)

for leprosy reactions, [426–427](#)

for lupus pernio, [754](#)

for lymphomatoid papulosis, [479](#)

for morphea, [513](#)

for mucous membrane pemphigoid, [519](#)

for nail psoriasis, [545](#)

for oral lichen planus, [574](#)

- for palmoplantar pustulosis, [583](#)
- for pityriases rubra pilaris, [630](#)
- for pityriasis lichenoides chronica, [632–633](#)
- for pityriasis lichenoides et varioliformis acuta, [636](#)
- for pompholyx, [321](#)
- for psoriasis, [253](#), [697–699](#), [701–702](#)
 - erythrodermic, [705](#)
 - monitoring guidelines for, [698–699](#)
 - pustular, [707](#)
- for pyoderma gangrenosum, [714](#)
- for reactive arthritis, [726](#), [728](#)
- for relapsing polychondritis, [734](#)
- for sarcoidosis, [752–753](#)
- for scleredema, [761](#), [763](#)
- for scleroderma, [764](#)
- for scleromyxedema, [434](#)
- for subacute cutaneous lupus erythematosus, [797](#), [799](#)
- for systemic lupus erythematosus, [431](#)
- for systemic sclerosis, [765–766](#)

Methoxsalen

- for pityriasis lichenoides, [636](#)
- for pityriasis lichenoides chronica, [633](#)

8-methoxypsoralen

- for chronic palmoplantar eczema, [320](#)
- for psoriasis, [701](#)

Methyl aminolaevulinate, *See* [Photodynamic therapy](#)

Methylcobalamin, for postherpetic neuralgia, [343](#)

Methylene blue

for myxoid cyst, [542](#)

for pruritus ani, [686–687](#)

1-Methylnicotinamide, for rosacea, [747](#)

Methylprednisolone

for alopecia areata, [31](#)

for Behçet disease, [91](#)

for bullous pemphigoid, [118](#)

for cytophagic histiocytic panniculitis, [589](#)

for dermatitis-eosinophilia syndrome, [252](#)

for eosinophilic fasciitis, [216–217](#)

for erosive pustular dermatosis, [234](#)

for erythema elevatum diutinum, [241](#)

for febrile ulceronecrotic Mucha-Habermann disease, [636](#)

for graft-*versus*-host disease, [299](#)

for human parvovirus B19 infection, [605](#)

for Kawasaki disease, [395](#)

for livedo reticularis, [458](#)

for lupus panniculitis, [587](#)

for miliaria profunda, [507](#)

for morphea, [513](#)

for necrobiosis lipoidica, [551](#)

for paronychia, [601](#)

for pemphigus, [614](#)

for postherpetic neuralgia, [342](#)

for pretibial myxedema, [670](#)

for pruritus ani, [687](#)

for pyoderma gangrenosum, [712](#)

for relapsing polychondritis, [734](#)

- for Stevens-Johnson syndrome, [832](#)
- for subcorneal pustular dermatosis, [803](#)
- for subcutaneous fat necrosis of newborn, [806](#)
- for Sweet syndrome, [808](#)

Metronidazole

- for decubitus ulcers, [182](#)
- for *Demodex* folliculitis, [279](#)
- for erythema annulare centrifugum, [235](#)
- for granulomatous cheilitis, [315](#)
- for lichen planus, [442](#)
- for ocular rosacea, [750](#)
- for perioral dermatitis, [620](#)
- for rosacea, [744–748](#)
- for rosacea lymphedema, [750](#)
- for seborrheic eczema, [771](#), [773](#)
- for Sweet syndrome, [808](#)

Miconazole

- for diaper dermatitis, [204](#)
- for erythrasma, [248](#)
- for pitted and ringed keratolysis, [626](#)
- for seborrheic eczema, [773–774](#)

Microangiopathy, for lipodermatosclerosis, [455](#)

Microarray technology, for rubella, [848](#)

Micrococcus kristinae, [627](#)

Micrococcus lylae, [627](#)

Micrococcus sedentari, [626–628](#)

Microculture, for leishmaniasis, [419](#)

Microdebrider, for rhinophyma, [738](#)

Microdermabrasion

for acne vulgaris, [10](#)

for melasma, [661](#)

for striae, [796](#)

Microfilaridermias, [572](#)

Microlobule, [584](#)

Micromarsupialization, in mucoceles, [516](#)

Microscopic polyarteritis (MPA), [177](#)

Microsporum

dermatophytosis from, [820](#)

tinea capitis from, [816](#), [818](#)

Microsporum audouinii, [816](#)

Microsporum canis, [816](#), [818](#)

Microsurgery, for lymphedema, [471](#)

Microwave based device, for hyperhidrosis, [357](#)

Midborderline leprosy, [426](#)

Migalastat, for Fabry disease, [268–269](#), [271](#)

Miliaria, [505–507](#), [505f](#)

Miliaria crystallina, [505–506](#)

Miliaria profunda, [505](#), [507](#)

Miliaria rubra, [505–506](#)

Milnacipran

for burning mouth syndrome, [122](#)

for vulvodynia, [865](#)

Milroy disease, [470](#)

Miltefosine, for leishmaniasis, [420](#)

Miniature yaws, [624](#)

Minipunch grafting, for vitiligo, [862](#)

Minocycline

- for actinomycosis, [22](#)
- for Behçet disease, [92](#)
- for bullous pemphigoid, [117](#)
- for calcinosis cutis, [125–126](#)
- for confluent and reticulated papillomatosis, [161–164](#)
- for cutaneous polyarteritis nodosa, [177–178](#)
- for erythema nodosum, [247](#)
- for fish tank granuloma, [527](#)
- for follicular mucinosis, [276](#)
- for folliculitis decalvans, [282](#)
- for granuloma annulare, [304](#)
- for granulomatous cheilitis, [312](#), [315](#)
- for leprosy, [426](#)
- for livedo reticularis, [458–459](#)
- for Melkersson-Rosenthal syndrome, [315](#)
- for MRSA, [287](#)
- for mucous membrane pemphigoid, [518](#)
- for prurigo pigmentosa, [676](#)
- for pyoderma gangrenosum, [712](#)
- for rosacea, [745](#)
- for rosacea fulminans, [751](#)
- for sarcoidosis, [754](#)
- for scleroderma, [764](#)
- for steatocystoma multiplex, [788](#)
- for subcorneal pustular dermatosis, [803](#)
- for Wells syndrome, [869](#)

Minoxidil

- for alopecia areata, [30](#), [32](#)
- for androgenetic alopecia, [38](#)
- for pseudofolliculitis barbae, [691](#)

Mirtazapine, for pruritus, [685](#)

Misoprostol, for erythromelalgia, [259](#)

Mitomycin C

- for extramammary Paget disease, [266](#)
- for keloids, [400](#)
- for mucous membrane pemphigoid, [518](#)

Mizolastine, for chronic urticaria, [841t](#)

Mizoribine

- for cutaneous polyarteritis nodosa, [178](#)
- for subcorneal pustular dermatosis, [804](#)

Modified Jaipur block, for postherpetic neuralgia, [342](#)

Modified Welsh regimen, for actinomycetoma, [525](#)

Mohs micrographic surgery

- for atypical fibroxanthoma, [63](#)
- for basal cell carcinoma, [80](#)
- for basal cell carcinomas, [563](#)
- for Bowen's disease, [115](#)
- for dermatofibrosarcoma protuberans, [195–196](#)
- for extramammary Paget disease, [265](#)
- for keratoacanthoma, [402–403](#)
- for lentigo maligna, [423](#)
- for malignant melanoma, [488](#)
- for melanoma in situ, [422–423](#)
- for Merkel cell carcinoma, [496–497](#)
- for squamous cell carcinoma, [780](#), [784](#)

- for xeroderma pigmentosum, [875](#)
- Moist wound environment, maintenance of, in decubitus ulcers, [182](#)
- Moisturizers
 - for atopic dermatitis, [54](#)
 - barrier-strength, for allergic contact dermatitis, [27](#)
 - for ichthyosis, [366–367](#)
 - for irritant contact dermatitis, [378](#)
 - for xerosis, [879–880](#)
- Molecular adsorbent recirculating system, for cholestatic itch, [681](#)
- Molluscum contagiosum, [508–511](#), [508f](#)
 - scarring, [509](#)
- Mometasone
 - for allergic contact dermatitis, [27](#)
 - for alopecia areata, [31](#)
 - for balanitis, [77](#)
 - for dyshidrotic palmar eczema, [320](#)
 - for geographic tongue, [291](#)
 - for lichen sclerosis, [446](#)
 - for sarcoidosis, [753](#)
- Monobenzyl ether of hydroquinone, for vitiligo, [863](#)
- Monochloroacetic acid, for warts, [855](#)
- Monochromatic excimer light, for vitiligo, [861](#)
- Monoclonal antibodies, for anthrax, [97–98](#)
- Monoclonal gammopathy
 - scleredema and, [761](#)
 - subcorneal pustular dermatosis and, [802–803](#)
 - xanthomas and, [870](#)
- Monoclonal hypergammaglobulinemia, [762](#)

Monocyte adsorption apheresis, for pyoderma gangrenosum, [713](#)

Montelukast, for aphthous stomatitis, [53](#)

Morbihan's disease (rosacea lymphedema), [750](#)

Morphea, [512–514](#), [512f](#)

- panniculitis and, [585](#)

Mosquito-bite allergy, [592](#)

Mosquito repellents, [103](#)

Mother yaws, [624](#)

Moxidectin

- for bed bugs, [89](#)
- for onchocerciasis, [573](#)

Moxifloxacin

- for leprosy, [426](#)
- for lymphogranuloma venereum, [475](#)
- for *Mycobacterium abscessus* infection, [530t](#), [531](#)
- for plague, [100](#)
- for Q fever, [742](#)

MPNSTs, *See* [Malignant peripheral nerve sheath tumors](#)

MQX-503, for Raynaud's phenomenon, [723](#)

MRI

- for actinomycosis, [21](#)
- for cellulite, [136](#)
- for dermatomyositis, [198](#)
- for eosinophilic fasciitis, [216](#)
- for hemangiomas, [323](#)
- for Kawasaki disease, [395](#)
- for lipodermatosclerosis, [455](#)
- for lymphangioma circumscriptum, [467](#)

- for lymphedema, [470](#)
- for Merkel cell carcinoma, [496](#)
- for morphea, [513](#)
- for myxoid cyst, [541](#)
- for neurofibromatosis type 1, [559](#)
- for nevoid basal cell carcinoma syndrome, [562](#)
- for port wine stain, [653](#)
- for subcutaneous fat necrosis of newborn, [805](#)

MRSA, *See* [Methicillin-resistant *Staphylococcus aureus*](#)

mTOR inhibitors, for paronychia, [601–602](#)

Muckle-Wells syndrome (MWS), [165](#)

Mucocele, [515–516](#), [515f](#)

Mucosal manifestations, of erythema multiforme, [242](#)

Mucous extravasation cyst, [515](#)

Mucous membrane pemphigoid, [517–521](#), [517f](#)

Mucous patches, [811](#)

Mucous retention cyst, [515](#)

Multiple cutaneous and uterine leiomyoma, [416](#)

Multiple keratoacanthoma, [403–404](#)

Multiple ovoid-shape ablation method, for syringoma, [815](#)

Multiple seborrheic keratoses, [775–776](#)

Multiple type II gastric carcinoid, [274](#)

Mupirocin

- for confluent and reticulated papillomatosis, [163](#)
- for cutaneous candidiasis, [172](#)
- for epidermolysis bullosa, [227](#)
- for impetigo, [370–371](#)
- for MRSA, [286–287](#), [501](#)

- resistance to, [499–500](#)
- for paronychia, [600](#)
- for pitted and ringed keratolysis, [626–627](#)
- for staphylococcal scalded skin syndrome, [785](#)

Murine typhus, [741](#)

Muscle disease, for dermatomyositis, [201](#)

Mutation identification, neurofibromatosis type 1, [559](#)

Mycetoma, [522–525](#), [522f](#)

Mycobacterial (atypical) skin infections, [526–531](#), [526f](#)

Mycobacterium abscessus infection, [t530](#)

Mycobacterium bovis, [838](#)

Mycobacterium chelonae infection, [529](#)

Mycobacterium fortuitum infections, [t530](#)

- in furunculosis, [286](#)

Mycobacterium kansasii infections, [529](#)

Mycobacterium leprae, [426](#)

Mycobacterium marinum infections, [526](#)

Mycobacterium tuberculosis, [838](#)

Mycobacterium ulcerans infections, [528](#)

Mycolactone, [528](#)

Mycophenolate mofetil

- for atopic dermatitis, [57](#), [61–62](#)
- for bullous pemphigoid, [118](#)
- for chronic actinic dermatitis, [156](#)
- for cutaneous polyarteritis nodosa, [178](#)
- for dermatitis herpetiformis, [192](#)
- for dermatomyositis, [200](#)
- for diffuse cutaneous systemic sclerosis, [765–766](#)

- for dyshidrotic eczema, [321](#)
 - for eosinophilic fasciitis, [217](#), [219](#)
 - for epidermolysis bullosa acquisita, [230](#)
 - for erythema nodosum, [247](#)
 - for graft-*versus*-host disease, [299](#)
 - for Henoch-Schönlein purpura, [431](#)
 - for lichen planopilaris, [439](#)
 - for morphea, [514](#)
 - for mucous membrane pemphigoid, [519](#)
 - for necrobiosis lipoidica, [550](#)
 - for nodular vasculitis, [587](#)
 - for oral lichen planus, [574](#)
 - for orofacial granulomatosis, [315](#)
 - for pemphigus, [614](#)
 - for pemphigus foliaceus, [613](#)
 - for pemphigus vulgaris, [613](#)
 - for psoriasis, [703](#), [706](#)
 - for pyoderma gangrenosum, [714](#)
 - for relapsing polychondritis, [734](#)
 - for sarcoidosis, [752](#), [754](#)
 - for subacute cutaneous lupus erythematosus, [797](#)
- Mycophenolate sodium
- for atopic dermatitis, [62](#)
 - for Behçet disease, [93](#)
 - for scleroderma-related interstitial lung disease, [766](#)
 - for subacute cutaneous lupus erythematosus, [798](#)
- Mycoplasma arginini*, [217](#)
- Mycosis fungoides, [532–537](#), [532f](#)

- advanced stage (IIB-IVB), [533](#)
- diagnosis of, [532](#)
- follicular mucinosis associated with, [275](#)
- “looping back” in, [534](#)
- lymphomatoid papulosis and, [477](#), [479–480](#)
- pathogenesis of, [532](#)
- recurrence of, [533](#)
- staging in, [532](#)

Mycostatin, for diaper dermatitis, [205](#)

Myelodysplastic syndrome

- relapsing polychondritis and, [734](#)
- Sweet syndrome and, [808](#)

Myeloma, in subcorneal pustular dermatosis, [802](#)

Myelomonocytic leukemia, chilblains with, [145](#)

Myeloproliferative disorders, in erythromelalgia, [258–259](#)

Myiasis, [538–540](#), [538f](#)

Myositis-specific autoantibodies, dermatomyositis, [199](#)

Myxoedema, palmoplantar keratoderma and, [580](#)

Myxoid cyst, [541–542](#), [541f](#)

N

Nadifloxacin, for furunculosis, [287](#)

Nadolol, for flushing reactions in rosacea, [749](#)

Naftifine

for cutaneous candidiasis, [172](#)

for tinea pedis, [821](#)

Nail cosmetics, [543](#)

Nail psoriasis, [543–547](#), [543f](#)

Nailfold capillaroscopy, for Raynaud's phenomenon, [722–725](#)

Nalfurafine hydrochloride, for uremic pruritus, [683](#)

Nalmefene, for cholestatic pruritus, [680](#)

Naloxone

for cholestatic pruritus, [680](#)

for rosacea, [749](#)

Naltrexone

for aquagenic pruritus, [377](#)

for cholestatic pruritus, [680](#)

for pruritus, [685](#)

for pruritus vulvae, [689](#)

for psychogenic excoriation, [708](#), [710](#)

for renal itch, [682](#)

Napkin dermatitis, [203](#)

Naproxen, for erythema nodosum, [246](#)

Narrowband ultraviolet B

for actinic prurigo, [19](#)

for aquagenic pruritus, [375](#)

for capillaritis, [133](#)

for chronic hand eczema, [320](#)
for cutaneous mastocytosis, [490](#)
for discoid eczema, [207](#)
for graft-*versus*-host disease, [300](#)
for Hailey-Hailey disease, [318](#)
for hydroa vacciniforme, [352](#)
for indolent systemic mastocytosis, [490](#)
for irritant contact dermatitis, [380](#)
for Langerhans cell histiocytosis, [410](#)
for lichen nitidus, [436](#)
for lichen planus, [441](#)
for malignant atrophic papulosis, [483](#)
for morphea, [513](#)
for mycosis fungoides, [535](#)
for Netherton syndrome, [367](#)
for perforating dermatoses, [617](#)
for photodermatoses, [262](#)
for pityriases rubra pilaris, [629](#)
for pityriasis lichenoides chronica, [633](#)
for pityriasis lichenoides et varioliformis acuta, [636](#)
for polymorphic light eruption, [643](#)
for prurigo nodularis, [672](#)
for psoriasis, [697](#), [701](#)
for psychogenic excoriation, [708](#), [710](#)
for reactive perforating collagenosis, [617](#)
for renal itch, [682](#)
for scleredema, [762](#)
for seborrheic eczema, [773](#)

- for small plaque parapsoriasis, [598](#)
- for subcorneal pustular dermatosis, [802–803](#)
- for uremic pruritus, [682](#)

National Comprehensive Cancer Network (NCCN), [485](#)

Nd:YAG laser

- for amyloidosis, [35](#)
- for angiolymphoid hyperplasia with eosinophilia, [42](#)
- for Becker nevus, [85](#)
- for cellulite, [137](#)
- for dissecting cellulitis of scalp, [212](#)
- for folliculitis decalvans, [282](#)
- for granuloma annulare, [306](#)
- for hidradenitis suppurativa, [346](#)
- for lentigo maligna, [424](#)
- for melasma, [495](#), [661](#)
- for Peutz-Jeghers syndrome, [621–622](#)
- for porokeratosis, [647](#)
- for port wine stain, [657](#)
- for pseudofolliculitis barbae, [694](#)
- for pyogenic granuloma, [717](#)
- for rhinophyma, [738](#)
- for rosacea, [748](#)
- for striae, [795](#)
- for urticaria pigmentosa, [491](#)
- for warts, [856](#)
- for xanthelasma palpebrarum, [871](#)

Necrobiosis lipoidica, [548–551](#), [548f](#)

Necrobiotic xanthogranulomas, [870](#)

Necrolytic acral erythema, [552–553](#), [552f](#)

Necrolytic migratory erythema, [554–556](#), [554f](#)

Necrotic debris, removal of, [181](#)

Needle aspiration, for lymphogranuloma venereum, [475](#)

Neisseria gonorrhoea, causing gonorrhea, [295](#)

Nematocysts, in jellyfish sting, [381](#)

Neodymium:yttrium-aluminium-garnet laser, *See* [Nd:YAG laser](#)

Neonates

- staphylococcal scalded skin syndrome in, [785–787](#)
- varicella in, [844](#)

Neoplasms

- in erythema annulare centrifugum, [235](#)
- in nevus sebaceus, [567](#)

Nephrocalcinosis, [805–806](#)

Nephrogenic systemic fibrosis, [557–558](#), [557f](#)

Netherton syndrome, [253](#), [366](#)

Neuralgia, postherpetic, [340](#), [341t](#)

Neuraxial blocks, for herpes zoster, [342](#)

Neuroborreliosis, [465](#)

Neurodermatitis circumscripta (lichen simplex chronicus), [448–450](#), [448f](#)

Neurofibromas, [559](#)

Neurofibromatosis type 1, [559–561](#), [559f](#)

- for juvenile xanthogranuloma, [389](#)
- triple association of, [388–389](#)

Neurofibromin, [559](#)

Neurologic disease, xeroderma pigmentosum and, [875](#)

Neuropathic itch, [679](#)

Neurosyphilis, [811](#)

Neurotic (psychogenic) excoriation, [708–710](#), [708f](#)

Neutropenic fever, miliaria-rash after, [506](#)

Neutrophilic dermatosis of the dorsal hands (NDDH), [807](#)

Nevoid basal cell carcinoma syndrome, [562–566](#), [562f](#)

- chemoprevention for, [b565](#)

“Nevus flammeus,” [653–657](#)

Nevus/nevi

- atypical, [66–69](#), [66f](#)
- Becker, [84–86](#), [84f](#)

Nevus sebaceus, [567–568](#), [567f](#)

Nevus simplex (salmon patch, angel kiss), [653](#)

NF- κ B specific inhibitor DHMEQ, for antiphospholipid syndrome, [48](#)

NF1, *See* [Neurofibromatosis type 1](#)

Niacinamide

- for erythema elevatum diutinum, [239](#)
- for granuloma annulare, [305](#)
- for linear IgA bullous dermatosis, [451](#)
- for melasma, [494](#)

Nickel allergy, pruritus ani and, [686](#)

Nickel-induced contact dermatitis, [28](#)

Nicomide, for rosacea, [747](#)

Nicotinamide

- for bullous pemphigoid, [117](#)
- for dermatitis herpetiformis, [193](#)
- for erythema elevatum diutinum, [239](#)
- for mucous membrane pemphigoid, [518](#)
- for necrobiosis lipoidica, [549](#)
- for polymorphic light eruption, [644](#)

for xerosis, [879](#)

Nicotine patches

for Behçet disease, [93](#)

for erythema elevatum diutinum, [241](#)

for livedoid vasculopathy, [462](#)

for malignant atrophic papulosis, [482](#)

Nicotinic acid

flushing induction, [273](#)

for pyoderma gangrenosum, [712](#)

Nifedipine

for chilblains, [146](#)

for leiomyoma, [416–417](#)

for Raynaud's disease, [722](#)

for Raynaud's phenomenon, [722–723](#)

for scleroderma, [764](#)

NightWatch, [591](#)

Nit(s), [606](#)

Nitrite, acidified

for chilblains, [146](#)

for molluscum contagiosum, [508](#)

Nitrogen mustard

for alopecia areata, [32](#)

for Langerhans cell histiocytosis, [410](#)

for large plaque parapsoriasis, [599](#)

for mycosis fungoides, [535](#)

for pyoderma gangrenosum, [713](#)

for small plaque parapsoriasis, [598](#)

Nitroglycerin

- for aquagenic pruritus, [377](#)
- for chondrodermatitis nodularis helices chronicus, [147](#)
- for vulvodynia, [865–866](#)
- Nitroglycerine, for Raynaud's phenomenon, [723](#)
- Nivolumab, for melanoma, [485](#), [487](#)
- Nix crème rinse, for pediculosis capitis, [607](#)
- NLRP3 mutation, [165](#)
- Nocardia*, [522](#)
- Nodular vasculitis, [584](#), [587](#)
- Nodules, in port wine stain, [653](#)
- Nodulocystic acne, *See* [Acne vulgaris](#)
- Non-Hodgkin lymphomas (NHLs), mycosis fungoides and, [532](#)
- Nonablative 1550-nm fractional laser therapy, for melasma, [495](#)
- Nonablative lasers, for striae, [794](#)
- Nonblanchable erythema, in decubitus ulcers, [182](#)
- Noncoherent light, for porphyria cutanea tarda, [652](#)
- Nonsteroidal antiinflammatory drugs (NSAIDs)
 - for basal cell carcinoma, [566](#)
 - for cryopyrin associated periodic syndromes, [165](#), [167](#)
 - for hereditary hemorrhagic telangiectasia, [330](#)
 - human parvovirus B19, [603](#)
 - for leprosy reactions, [426](#)
 - for nodular vasculitis, [587](#)
 - for reactive arthritis, [726](#)
- Nordihydroguaiaretic acid, for MRSA, [503](#)
- Norfloxacin, for granuloma inguinale, [310](#)
- Nortriptyline, for postherpetic neuralgia, [341–342](#), [341t](#)
- Notalgia paresthetica (NP), [569–570](#), [569f](#), [679](#)

Nucleic acid amplification tests (NAATs)
for *Chlamydia trachomatis*, [295–296](#), [475](#)
for *Neisseria gonorrhoea*, [295–296](#)

Nucleolar antibodies, scleroderma and, [765–767](#)

Nummular eczema, [206–208](#), [206f](#)

Nutraceutical, for warts, [858](#)

Nutritional deficiency
geographic tongue and, [291](#)
necrolytic migratory erythema and, [554](#)

Nutritional/dietary management
for acrodermatitis enteropathica, [13](#)
for decubitus ulcers, [185](#)
of oculocutaneous tyrosinemia, [581](#)
for pseudoxanthoma elasticum, [695](#)

Nutritional support
for epidermolysis bullosa, [227](#)
for Stevens-Johnson syndrome, [830](#)
for toxic epidermal necrolysis, [830](#)

NVC-422, for impetigo, [370](#)

Nystatin
for cutaneous candidiasis, [172](#)
for diaper dermatitis, [204](#)
for erosive pustular dermatosis, [233](#)
for mucous membrane pemphigoid, [517](#)
for paronychia, [602](#)

O

Obesity

- causing acanthosis nigricans, [1](#)
- confluent and reticulated papillomatosis and, [162](#)

Oblimersen sodium, for melanoma, [488](#)

Observation

- in cat scratch disease, [134](#)
- dermatologic, of decubitus ulcers, [183](#)
- in follicular mucinosis, [275](#)
- in nevus sebaceus, [567](#)

Obsessive-compulsive disorder, psychogenic excoriation and, [709](#)

Occlusive dressings

- for discoid eczema, [207](#)
- for keloids, [398](#)
- for morphea, [513–514](#)
- for myiasis, [538](#)
- for prurigo nodularis, [673](#)
- for radiation dermatitis, [719](#)

Octreotate, for necrolytic migratory erythema, [555](#)

Octreotide

- carcinoid treated with, [274](#)
- for Graves' ophthalmopathy, [670](#)
- for necrolytic migratory erythema, [554–555](#)
- for pancreatic panniculitis, [588](#)
- for pretibial myxedema, [668](#), [670](#)
- for rosacea, [747](#)
- for thyroid-associated dermopathy, [670](#)

for yellow nail syndrome, [881–882](#)

Ocular involvement

in juvenile xanthogranuloma, [388](#)

in pseudoxanthoma elasticum, [695](#)

in rosacea, [744](#), [750](#)

in syphilis, [811](#)

Ocular rosacea, [750](#)

Oculocutaneous tyrosinemia, [579](#), [581](#)

Odontogenic infection, chronic pigmented purpura associated with, [132](#)

Ofloxacin

for granuloma annulare, [304](#)

for leprosy, [426](#)

for Q fever, [743](#)

Ofuji's papuloerythroderma, [252](#)

Oil baths, for xerosis, [879](#)

OK-432 therapy, for lymphangioma circumscriptum, [467–468](#)

Olanzapine

for burning mouth syndrome, [122](#)

for delusional parasitosis, [188–189](#)

for dermatitis artefacta, [191](#)

for psychogenic excoriation, [708](#), [710](#)

for trichotillomania, [837](#)

"Old age spot," [658](#)

Omalizumab, [375](#)

for bullous pemphigoid, [119](#)

for chronic spontaneous urticaria, [841](#)

for mastocytoses, [492](#)

Omega-3

- for aphthous stomatitis, [52](#)
- for hydroa vacciniforme, [353](#)
- for ocular rosacea, [751](#)
- Omeprazole, for palmoplantar pustulosis, [582](#)
- Omiderm, for staphylococcal scalded skin syndrome, [787](#)
- OnabotulinumtoxinA injections, for vulvodynia, [866](#)
- Onchocerca volvulus*, [571](#)
- Onchocerciasis, [571–573](#), [571f](#), [757–758](#)
- Onchocerciasis Control Program (OCP), [571](#)
- Onchocerciasis Elimination Program in the Americas (OEPA), [571](#)
- Ondansetron, for rosacea, [749](#), [751](#)
- Onion juice, for alopecia areata, [33](#)
- Onychomycosis, [823](#)
 - distal subungual, [823](#)
 - proximal subungual, [823](#)
 - white superficial, [823](#)
- Onychomycosis Severity Index, [824](#)
- Oophorectomy, for autoimmune progesterone dermatitis, [72](#)
- Opaque photoprotective agents, in visible light range, [261](#)
- Ophthalmia neonatorum, [297](#)
- Opiates
 - for Stevens-Johnson syndrome, [830](#)
 - for toxic epidermal necrolysis, [830](#)
- Opioids, for postherpetic neuralgia, [340](#), [341t](#)
- Oral contraceptives
 - for acne vulgaris, [7](#)
 - for autoimmune progesterone dermatitis, [70](#)
 - for Behçet disease, [93](#)

- for Fox-Fordyce disease, [284–285](#)
- for intrahepatic cholestasis of pregnancy, [665](#)
- for melasma, [493](#)
- for pemphigoid gestationis, [663](#)
- for rosacea, [747](#)
- Oral fluid assays, for measles diagnosis, [850](#)
- Oral Janus kinase inhibitor, for nail psoriasis, [547](#)
- Oral lichen planus, [574–576](#), [574f](#)
- Oral lichenoid reaction, [574](#)
- Oral methylprednisolone, for necrobiosis lipoidica, [549](#)
- Oral thermal-induced flushing, [273](#)
- OrCel, for epidermolysis bullosa, [226](#)
- Orf, [577–578](#), [577f](#)
- Organochloride insecticide, for scabies, [757](#)
- Oritavancin, for MRSA, [502](#)
- Ornithonyssus bacoti* (tropical rat mite), [591](#)
- Orofacial granulomatosis, [312–315](#)
- Osteoarticular manifestations, of palmoplantar pustulosis, [582](#)
- Osteoma cutis, Becker nevus with, [84](#)
- Osteopenia, corticosteroid-induced, [612](#)
- Osteophytes, for myxoid cyst, [541](#)
- Ovarian cancer, in polycystic ovary syndrome, [641](#)
- Ovide, for pediculosis capitis, [607](#)
- Ovulation, oral inhibitors of, for rosacea, [747](#)
- Oxacillin
 - for cellulitis and erysipelas, [141](#)
 - for staphylococcal scalded skin syndrome, [785–786](#)
- Oxalosis, [585](#)

Oxandrolone, for lipodermatosclerosis, [456](#)

Oxatomide

for pruritus senilis, [685](#)

for pruritus vulvae, [690](#)

Oxazolidinones, for *Nocardia* infection, [525](#)

Oxcarbazepine, in notalgia paresthetica, [569–570](#)

Oxybutynin

for dyshidrotic eczema, [321](#)

for hyperhidrosis, [356](#)

Oxycodone, for postherpetic neuralgia, [341t](#), [342](#)

Oxymetazoline

for rosacea, [749](#)

rosacea-associated flushing, [274](#)

Oxytetracycline

for ocular rosacea, [751](#)

for perioral dermatitis, [620](#)

for rosacea, [745](#)

Ozone therapy, for calciphylaxis, [130](#)

P

Paclitaxel

for basal cell carcinoma, [565](#)

for Kaposi sarcoma, [392](#)

for melanoma, [487](#)

Paget disease, extramammary, [265–267](#), [265f](#)

Palm and sore psoriasis, [697](#)

Palmitoylethanolamide, for vulvodynia, [866](#)

Palmoplantar keratoderma, [579–581](#), [579f](#)

Palmoplantar pustulosis, [582–583](#), [582f](#)

Pamidronate

for calcinosis cutis, [125](#)

for calciphylaxis, [129](#)

for subcutaneous fat necrosis of newborn, [805–806](#)

Pancreatic carcinoma, panniculitis caused by, [588](#)

Pancreatic duct stent, for pancreatic panniculitis, [587–588](#)

Pancreatic panniculitis, [585](#), [587–588](#)

Panniculitis, [584–589](#), [584f](#)

Panton-Valentine leukocidin *Staphylococcus aureus*, [499–504](#)

See also [Methicillin-resistant *Staphylococcus aureus* \(MRSA\)](#)

Papillomatosis, confluent and reticulated, [161–164](#), [161f](#)

Papillomatous dermatitis, [790](#)

Papular epidermal nevus, [221](#)

Papular purpuric gloves-and-socks syndrome (PPGSS), [603](#)

Papular urticaria, [590–592](#), [590f](#)

Papules, of malignant atrophic papulosis, [481](#)

Papulopustular acne, *See* [Acne vulgaris](#)

Papulopustular rosacea, [746–748](#)

Papulosis, malignant atrophic, [481–483](#), [481f](#)

Paracoccidioides brasiliensis, [593](#)

Paracoccidioidomycosis, [593–596](#), [593f](#)
dissemination of, [593](#)

Paraffin
for ichthyosis, [366](#)
for xerosis, [880](#)

Paraileostomy recontouring, for stoma care, [792](#)

Paraneoplastic pemphigus, [611](#)

Paraproteinemia, scleredema and, [763](#)

Parapsoriasis, [597–599](#), [597f](#)

Parasite, in folliculitis, [278](#)

Parasitosis, delusional, [187–189](#), [187f](#), [708](#)

Parathyroidectomy
for calciphylaxis, [128](#)
for secondary hyperparathyroidism, [684](#)

Paravertebral block, for notalgia paresthetica, [570](#)

Parkinsonism, neuroleptic-induced, seborrheic eczema and, [771](#)

Paromomycin, for leishmaniasis, [418](#), [420](#)

Paronychia, [600–602](#), [600f](#)

Paroxetine
for burning mouth syndrome, [122](#)
for itch associated with malignancy, [684](#)
for psychogenic excoriation, [709](#)
for psychogenic pruritus, [685](#)

Paroxysmal pain, in leiomyoma, [416](#)

Parvovirus infection, [603–605](#), [603f](#)

Patch testing

- for acute generalized exanthematous pustulosis, [25](#)
- for allergic contact dermatitis, [26](#)
- for autoimmune progesterone dermatitis, [71](#)
- for discoid eczema, [206](#)
- for drug eruptions, [213](#)
- for irritant contact dermatitis, [378](#)
- for peristomal dermatitis, [792](#)
- for pruritus ani, [686](#)
- for pruritus vulvae, [689](#)

Patched gene (*PTCH*) mutations, in nevoid basal cell carcinoma syndrome, [562](#)

Pathologic hyperhidrosis, [354](#)

Patient education, for atopic dermatitis, [54](#), [58](#)

Paxil, for trichotillomania, [837](#)

PCR

- for *Coxiella burnetii*, [743](#)
- for fish tank granuloma, [526](#)
- for human parvovirus B19 infection, [604](#)
- for leishmaniasis, [419](#)
- for lymphocytoma cutis, [473](#)
- for *Mycobacterium ulcerans* infection, [528](#)
- for onychomycosis, [824](#)
- for tuberculosis, [838–839](#)

PDGFB gene, dermatofibrosarcoma protuberans, [195](#)

Pediatric dermatology, corrective camouflage in, [86](#)

Pediculicides, [606](#)

- pediculosis corporis, [609](#)
- suffocation-based, [608](#)

Pediculosis, [606–610](#), [606f](#)

Pediculosis capitis, [606–609](#)

Pediculosis corporis, [609](#)

Pediculosis pubis, [609](#)

Pediculus capitis, [606](#)

Pediculus humanus (body or clothing louse), [606](#)

Pegylated interferon alfa-2b

- for malignant melanoma, [486–487](#)
- for mycosis fungoides, [535](#)

Pegylated interleukin-2, for basal cell carcinoma, [82](#), [564–565](#)

Pegylated liposomal doxorubicin, for Kaposi sarcoma, [391](#), [393](#)

Pelagia noctiluca sting, [383](#)

Pelvic floor physical therapy, for vulvodynia, [864](#)

Pembrolizumab

- for melanoma, [485](#), [487](#)
- for Merkel cell carcinoma, [498](#)

Pemphigoid, bullous, [116–119](#), [116f](#)

Pemphigoid gestationis, [663](#)

- bullous lesions in, [663](#)
- maternal prognosis in, [663](#)
- polymorphic eruption of pregnancy and, [662](#)

Pemphigoid nodularis, [674](#)

Pemphigus, [611–615](#), [611f](#)

- variants of, [611](#)

Pemphigus foliaceus, [612](#)

Pemphigus vulgaris, [611](#)

Penciclovir, for herpes labialis, [338](#)

D-penicillamine

for diffuse systemic sclerosis, [766](#)

for eosinophilic fasciitis, [216](#), [218](#)

for scleredema, [761](#), [763](#)

for scleroderma, [764](#)

Penicillin

for actinomycosis, [21–22](#)

for acute generalized exanthematous pustulosis, [24](#)

for aphthous stomatitis, [52](#)

for blistering distal dactylitis, [108](#)

for cellulitis, [139](#)

for erysipelas, [140](#)

for erythema nodosum, [247](#)

for gonorrhea, [296](#)

for impetigo, [370](#)

for psoriasis, [704](#)

for scleredema, [761](#), [763](#)

for syphilis, [811](#)

desensitization, [812](#)

Penis

extramammary Paget disease in, [265](#)

lichen sclerosus in, [447](#)

lymphangioma circumscriptum of, [468](#)

Pentamidine isethionate, for leishmaniasis, [418](#)

Pentavalent antimonials

for leishmaniasis, [418](#)

side effects of, [418](#)

Pentostatin, for graft-*versus*-host disease, [301](#)

Pentoxifylline

- for actinic prurigo, [18](#), [20](#)
- for allergic contact dermatitis, [28](#)
- for aphthous stomatitis, [51–52](#)
- for calciphylaxis, [130](#)
- for capillaritis, [133](#)
- for cutaneous polyarteritis nodosa, [178](#)
- for follicular mucinosis, [276](#)
- for granuloma annulare, [305](#)
- for leishmaniasis, [421](#)
- for leukocytoclastic vasculitis, [432](#)
- for lipodermatosclerosis, [454–456](#)
- for livedo reticularis, [458](#)
- for livedoid vasculopathy, [461](#)
- for mucous membrane pemphigoid, [521](#)
- for necrobiosis lipoidica, [549](#)
- for nephrogenic systemic fibrosis, [558](#)
- for perniosis, [146](#)
- for pretibial myxedema, [668–669](#)
- for radiation dermatitis, [720](#)
- for sarcoidosis, [756](#)
- for Schamberg's disease, [133](#)
- for Stevens-Johnson syndrome, [833](#)
- for toxic epidermal necrolysis, [830](#)
- for venous ulcers, [415](#)

PEP005 (ingenol mebutate) gel, for basal cell carcinoma, [565](#)

Perceptual retraining, for body dysmorphic disease, [111](#)

Percutaneous chemical sympathectomy, for hyperhidrosis, [355](#)

Perforating dermatoses, [616–618](#), [616f](#)

- clinicopathological features of, [616–618](#)
 - management strategy for, [616–618](#)
- Perforating folliculitis, [278](#), [616](#)
- Perianal ulceration, lymphogranuloma venereum and, [475](#)
- Perifollicular xanthoma, Fox-Fordyce disease and, [284](#)
- Periocular dermatitis, [619](#)
- Perioral dermatitis, [619–620](#), [619f](#)
 - Differential diagnoses of, [619](#)
 - management strategy for, [619–620](#)
- Periorbital hyperpigmentation, [659](#)
- Periorbital melanosis, [659](#)
- Peripheral ulcerative keratitis, [808](#)
- Peripheral vascular endothelial dysfunction, livedoid vasculopathy, [460](#)
- Peristomal pyoderma gangrenosum (PPG), [792](#)
- Peritoneal dialysis, staphylococcus scalded skin syndrome in, [787](#)
- Permethrin
 - for folliculitis, [279](#)
 - as insect repellent, [592](#)
 - for pediculosis capitis, [607](#)
 - for pediculosis corporis, [609](#)
 - for pediculosis pubis, [609](#)
 - for rosacea, [747](#)
 - for scabies, [590](#)
 - for tickborne illness, [102](#)
- Perniosis (chilblains), [145–146](#), [145f](#)
- Peroxisome proliferator-activated receptor γ -agonist, for lichen planopilaris, [440](#)
- Persistent agmination, of lymphomatoid papulosis, [480](#)

PET scans

- for dermatomyositis, [199](#)
- for Merkel cell carcinoma, [496](#)
- for neurofibromatosis type 1, [559](#)

Petrolatum-based formulations

- for diaper dermatitis, [204–205](#)
- for irritant contact dermatitis, [379](#)

Petroleum jelly, for pediculosis ciliaris, [609–610](#)

Peutz-Jeghers syndrome, [621–623](#), [621f](#)

- management strategy for, [621–623](#)

Pharmacotherapy, of trichotillomania, [837](#)

Pharyngeal infection, gonorrhea and, [297](#)

Phenformin, for malignant atrophic papulosis, [482](#)

Phenol

- for alopecia areata, [33](#)
- for molluscum contagiosum, [508](#)
- for pruritus ani, [686](#)
- for pyogenic granuloma, [718](#)
- for reactive perforating collagenosis, [617](#)

Phenoxybenzamine, for leiomyoma, [416–417](#)

Phenoxymethylpenicillin, for erysipelas, [140–141](#)

Phentolamine, for complex regional pain syndrome, [731](#)

Phenylalanine, restriction of, palmoplantar keratoderma and, [579](#)

Phenytoin

- for Fabry disease, [270](#)
- for pyoderma gangrenosum, [715](#)

Phialophora verrucosa, [152](#)

Phlebotomy therapy, for porphyria cutanea tarda, [651](#)

Phosphatidylcholine-based anticellulite gel, for cellulite, [138](#)

Phosphatidylserine-prothrombin complex antibodies, [177](#)

Phosphodiesterase-5 inhibitors

- for Raynaud's disease, [722](#)
- for Raynaud's phenomenon, [722](#)

Photo provocation testing, for hydroa vacciniforme, [351](#)

Photoaggravated pompholyx, [320](#)

Photoallergy, [26–28](#)

Photochemotherapy

- for granuloma annulare, [305](#)
- for Grover disease, [835](#)
- for large plaque parapsoriasis, [599](#)
- for mastocytoses, [490](#)
- for pityriasis lichenoides, [636](#)
- for pityriasis lichenoides chronica, [633](#)
- for polymorphic light eruption, [644](#)
- for psoriasis, [701](#)
- for severe erythrodermic acute graft-*versus* -host disease, [253](#)

Photodermatoses, with actinic prurigo, [19](#)

Photodynamic therapy (PDT), [233](#), [290](#)

- for acne vulgaris, [10](#)
- for actinic keratoses, [15–16](#)
- for angiolymphoid hyperplasia with eosinophilia, [43](#)
- for basal cell carcinoma, [82](#)
- for Bowen's disease, [114](#)
- for Darier disease, [180](#)
- for dissecting cellulitis of scalp, [211](#)
- for epidermodysplasia verruciformis, [225](#)

for erythroplasia of Queyrat, [115](#)
for extramammary Paget disease, [266](#)
for fish tank granuloma, [527](#)
for follicular mucinosis, [276](#)
for folliculitis, [278](#), [280](#)
for folliculitis decalvans, [283](#)
for granuloma annulare, [303](#)
for Hailey-Hailey disease, [318](#)
for inflammatory linear verrucous epidermal nevus, [222](#)
for Jessner lymphocytic infiltrate, [385](#)
for Kaposi sarcoma, [393](#)
for keratoacanthoma, [403](#)
for leishmaniasis, [420–421](#)
for lentigo maligna, [425](#)
for lichen sclerosus, [447](#)
for lymphocytoma cutis, [474](#)
for molluscum contagiosum, [510](#)
for mycosis fungoides, [535](#)
for necrobiosis lipoidica, [550](#)
for nevoid basal cell carcinoma syndrome, [562–564](#)
for nevus sebaceus, [568](#)
for onychomycosis, [824–825](#)
for perforating dermatoses, [618](#)
for perioral dermatitis, [620](#)
for port wine stain, [657](#)
for pyogenic granuloma, [716](#), [718](#)
for rosacea, [746](#)
for sarcoidosis, [756](#)

- for sebaceous hyperplasia, [769–770](#)
- for skin dermatophytosis, [822](#)
- for squamous cell carcinoma, [781](#), [783](#)
- for verrucous epidermal nevus, [222](#)
- for warts, [852](#), [856](#)
- for Zoon's balanitis, [78](#)
- Photoepilation lasers, for hirsutism, [359](#)
- Photopheresis
 - evidence-based practice of, [253](#)
 - for systemic sclerosis, [767](#)
- Photophobia, xeroderma pigmentosum and, [875](#)
- Photopneumatic therapy, for keratosis pilaris, [408](#)
- Photosensitivity
 - in dermatomyositis, [198](#)
 - xeroderma pigmentosum and, [873](#)
- Photosensitivity disorders, [352](#)
- Phototesting
 - for actinic prurigo, [18–19](#)
 - for atopic dermatitis, [61](#)
 - for atopic eruption of pregnancy, [667](#)
 - for erythropoietic protoporphyria, [262](#)
 - for intrahepatic cholestasis of pregnancy, [665–666](#)
 - for pityriasis lichenoides chronica, [633](#)
 - for subcorneal pustular dermatosis, [802](#)
- Photothermolysis
 - for actinic keratoses, [17](#)
 - for porphyria cutanea tarda, [650](#)
 - for port wine stain, [657](#)

Phototoxic dermatitis, [659](#)

Phthiriasis palpebrarum, [609–610](#)

Phthirus pubis (pubic/crab louse), [606](#)

Phymas, [737](#)

- rosacea and, [744](#)

Physalia physalis (Portuguese man-of-war), [381](#)

Physical therapy

- for complex regional pain syndrome, [731](#)
- for nephrogenic systemic fibrosis, [557](#)
- for scleredema, [763](#)
- for vulvodynia, [864–865](#)

Physical urticarias, in inducible urticaria, [372](#)

Physiotherapy, *See* [Physical therapy](#)

Physostigmine, pediculosis pubis, [609–610](#)

Phytoestrogens, for vasomotor menopausal symptoms, [274](#)

Picaridin, for bites and stings, [102](#)

Pigmented contact dermatitis, [659](#)

Pigmented hairy epidermal nevus, *See* [Becker nevus](#)

Pigmented purpuric dermatoses, [131–133](#), [131f](#)

Piloleiomyoma, [416](#)

Pilosebaceous unit, disorders of, [407](#)

Pimecrolimus

- for allergic contact dermatitis, [26–27](#)
- for atopic dermatitis, [55](#), [59](#)
- for balanitis, [78](#)
- for Behçet disease, [91](#)
- for chronic actinic dermatitis, [156](#)
- for chronic hand dermatitis, [320](#)

for cutaneous mastocytosis, [491](#)
for follicular mucinosis, [276–277](#)
for Fox-Fordyce disease, [285](#)
for granuloma annulare, [305](#)
for granuloma faciale, [307](#)
for Hailey-Hailey disease, [316](#)
for ichthyosis, [367](#)
for irritant contact dermatitis, [379](#)
for jellyfish stings, [383](#)
for Jessner lymphocytic infiltrate, [385](#)
for lichen nitidus, [437](#)
for lichen sclerosus, [446](#)
for lichen simplex chronicus, [449](#)
for oral lichen planus, [575](#)
for perioral dermatitis, [619–620](#)
for pompholyx, [319](#)
for pruritus vulvae, [689](#)
for psoriasis, [698](#)
 facial, [697](#)
 intertriginous, [697](#), [700](#)
for pyoderma gangrenosum, [712](#)
for rosacea, [747](#)
for sarcoidosis, [755](#)
for seborrheic dermatitis, [363](#)
for seborrheic eczema, [771–772](#)
for stoma care, [790](#)
for subacute cutaneous lupus erythematosus, [798](#)
for vitiligo, [363](#), [859](#), [861](#)

- for vulvar lichen simplex chronicus, [689](#)
- for Zoon's balanitis, [78](#)

Pimozide

- for delusional parasitosis, [187](#), [189](#)
- for dermatitis artefacta, [190](#)
- for psychogenic excoriation, [708](#), [710](#)

Pin-hole technique with squeezing, for sebaceous hyperplasia, [770](#)

Pinta, [624–625](#), [624f](#)

Pintides, [624](#)

Pioglitazone, [440](#)

Piperonyl butoxide, for pediculosis capitis, [608](#)

Pirfenidone

- for morphea, [514](#)
- for neurofibromatosis type 1, [561](#)

Piroxicam, for complex regional pain syndrome, [732](#)

Pitted keratolysis, [626–628](#), [626f](#)

Pityriases rubra pilaris, [629–631](#), [629f](#)

- photoaggravated, [630](#)
- subtypes of, [629](#)

Pityriasis alba, [362](#)

Pityriasis lichenoides, [636](#)

Pityriasis lichenoides chronica, [632–634](#), [632f](#)

Pityriasis lichenoides et varioliformis acuta, [635–637](#), [635f](#)

- management strategy for, [635](#)

Pityriasis rosea, [638–639](#), [638f](#)

- management strategy for, [638–639](#)

Pityriasis rubra pilaris, erythroderma and, [250](#)

Pityriasis versicolor, [362](#), [827–829](#), [827f](#)

Pityrosporum folliculitis, [278](#)

Pityrosporum orbiculare, seborrheic eczema and, [773–774](#)

Placebo effect, in vulvodynia, [865–866](#)

Plague, [99](#)

Plane xanthomas, [870](#), [872](#)

Plaques

in necrolytic acral erythema, [552](#)

in pinta, [624](#)

Plasma exchange/plasmapheresis

for α_1 -antitrypsin deficiency panniculitis, [589](#)

for antiphospholipid syndrome, [48](#)

for erythema elevatum diutinum, [241](#)

for erythropoietic protoporphyria, [263](#)

for Kawasaki disease, [397](#)

for pemphigoid gestationis, [664](#)

for pemphigus vulgaris, [614](#)

for porphyria cutanea tarda, [652](#)

for pretibial myxedema, [668](#), [670](#)

for pyoderma gangrenosum, [713](#)

for refractory cutaneous vasculitis, [432](#)

for relapsing polychondritis, [734](#)

scleromyxedema, [433](#)

for Stevens-Johnson syndrome, [832–833](#)

for toxic epidermal necrolysis, [830](#)

Platelet-derived growth factor, for pyoderma gangrenosum, [714](#)

Platelet-rich plasma (PRP)

in alopecia areata, [31–32](#)

in hair growth, [40](#)

Pleconaril, for enteroviruses, [851](#)

Pleomorphic dermal sarcoma (PDS), [63–64](#)

Plexiform neurofibromas, [559](#)

Plucking, for hirsutism, [358–359](#)

PLX4032, in melanoma, [488](#)

Pneumatic compression therapy, for lymphedema, [470](#)

Podophyllin

- for condyloma acuminata, [289](#)
- for warts, [857](#)

Podophyllotoxin

- for condyloma acuminata, [289](#)
- for molluscum contagiosum, [509](#)

Poikiloderma of Civatte, [659](#)

Polidocanol, for lipodermatosclerosis, [456](#)

Polyarteritis nodosa (PAN), [177](#)

Polycystic ovarian disease, with acanthosis nigricans, [3](#)

Polycystic ovary syndrome, [640–642](#), [640f](#)

Polycythemia vera, leukocytoclastic vasculitis associated with, [432](#)

Polycythemia vera-associated pruritus, [685](#)

Polymorphic eruption of pregnancy, [662](#)

Polymorphic light eruption, [643–645](#), [643f](#)

Polypodium leucotomos extract, for polymorphic light eruption and, [645](#)

Pompholyx, [319–321](#), [319f](#)

Porcine lipid cure, for myiasis, [539](#)

Porokeratoses, [646–649](#), [646f](#)

- disseminated forms of, [646](#)

Porphyria cutanea tarda, [650–652](#), [650f](#)

Porphyrins, [650](#)

Port wine stain, [653–657](#), [653f](#)
 watershed areas in, [653](#)

Portuguese man-of-war (*Physalia physalis*), [381](#)

Posaconazole
 for chromoblastomycosis, [152](#)
 for coccidioidomycosis, [158–159](#)
 for eumycetoma, [524](#)
 for histoplasmosis, [347](#), [349–350](#)
 for onychomycosis, [823](#)

Postherpetic neuralgia (PHN), [340](#), [341t](#)

Postinflammatory hyperpigmentation, [658](#), [658f](#)

Postkeloidectomy irradiation, for keloids, [400](#)

Poststreptococcal reactive arthritis, [729](#)

Potassium hydroxide, [820–821](#)
 for molluscum contagiosum, [510](#)

Potassium iodide
 for α_1 -antitrypsin deficiency panniculitis, [589](#)
 for cytophagic histiocytic panniculitis, [589](#)
 for erythema multiforme, [243](#)
 for erythema nodosum, [246](#)
 for nodular vasculitis, [587](#)
 for pyoderma gangrenosum, [714](#)
 for sporotrichosis, [777–778](#)
 for Sweet syndrome, [807](#)

Potassium titanyl phosphate, *See* [KTP laser](#)

Povidone-iodine
 for impetigo, [371](#)
 for molluscum contagiosum, [509](#)

traditional smallpox vaccination and, [96](#)

Powder chemical depilatories, for pseudofolliculitis barbae, [691](#), [694](#)

Poxviruses, inactivation of, [95](#)

PPG, *See* [Peristomal pyoderma gangrenosum](#)

Pravastatin, for xanthomas, [870–872](#)

Praziquantel, for rosacea, [747](#)

Prazosin

- for Raynaud's phenomenon, [724](#)
- for systemic sclerosis, [766](#)

Prednisolone

- for alopecia areata, [31](#)
- for autoimmune progesterone dermatitis, [71](#)
- for bullous pemphigoid, [117](#)
- for calcinosis cutis, [125](#)
- for chronic actinic dermatitis, [154](#)
- for complex regional pain syndrome, [732](#)
- for Darier disease, [180](#)
- for diffuse cutaneous systemic sclerosis, [766](#)
- for dissecting cellulitis of scalp, [212](#)
- for eosinophilic fasciitis, [218](#)
- for erysipelas, [141](#)
- for erythema elevatum diutinum, [239](#)
- for erythema multiforme, [243](#)
- for follicular mucinosis, [276](#)
- for juvenile xanthogranuloma, [390](#)
- for Kawasaki disease, [396](#)
- for Langerhans cell histiocytosis, [409](#)
- for livedo reticularis, [458](#)

for malignant atrophic papulosis, [483](#)
for mucous membrane pemphigoid, [519](#)
for pemphigoid gestationis, [663–664](#)
for pemphigus, [614](#)
for pityriasis rosea, [638](#)
for polymorphic eruption of pregnancy, [662–663](#)
for polymorphic light eruption, [644](#)
for pretibial myxedema, [670](#)
for pyoderma gangrenosum, [712](#)
for relapsing polychondritis, [734](#)
for rosacea fulminans, [751](#)
for rosacea lymphedema, [750](#)
for scleromyxedema, [433–434](#)
for Stevens-Johnson syndrome, [832](#)
for subcorneal pustular dermatosis, [803](#)
for tinea capitis, [818](#)
for Wells syndrome, [869](#)

Prednisone

for α_1 -antitrypsin deficiency panniculitis, [589](#)
for aphthous stomatitis, [51](#), [53](#)
for calcinosis cutis, [125](#)
for cytophagic histiocytic panniculitis, [588](#)
for dermatomyositis, [200](#)
for eosinophilic fasciitis, [216–217](#)
for epidermolysis bullosa acquisita, [229–230](#)
for erythema multiforme, [243](#)
for graft-*versus*-host disease, [299](#)
for granulomatous cheilitis, [314](#)

for hemangiomas, [322](#)
for Henoch-Schönlein purpura, [430–431](#)
for leprosy reactions, [426](#), [428](#)
for lichen planus, [444](#)
for linear IgA bullous dermatosis, [451](#)
for oral lichen planus, [574](#)
for papular urticaria, [590](#)
for pemphigus foliaceus, [613](#)
for pemphigus vulgaris, [613](#)
for polymorphic eruption of pregnancy, [662–664](#)
for pompholyx, [319](#)
for pyoderma gangrenosum, [712](#)
for rheumatoid arthritis-associated vasculitis, [431](#)
for sarcoidosis, [752–753](#), [756](#)
for scleredema, [763](#)
for subacute cutaneous lupus erythematosus, [799](#)
for subcutaneous fat necrosis of newborn, [805–806](#)
for Sweet syndrome, [807–808](#)
for urticarial vasculitis, [431](#)

Pregabalin

for burning mouth syndrome, [122](#)
for cutaneous leiomyoma, [417](#)
for leprosy, [427](#)
for neuropathic itch, [679](#)
for postherpetic neuralgia, [340–341](#), [341t](#)
for pruritus, [685](#)
for uremic pruritus, [683](#)
for vulvodynia, [865](#)

Pregnancy

- acne vulgaris and, [7–8](#)
- angiolymphoid hyperplasia with eosinophilia during, [41–43](#)
- antiphospholipid syndrome and, [47](#)
- cutaneous larva migrans and, [176](#)
- dermatoses, [662–667](#), [662f](#)
- gonorrhea and, [297](#)
- granuloma inguinale and, [310–311](#)
- herpes genitalis and, [334](#)
- histoplasmosis and, [350](#)
- human parvovirus B19 infection and, [604](#)
- lymphogranuloma venereum and, [475](#)
- melasma and, [493](#)
- prurigo pigmentosa and, [676](#)
- Rocky Mountain Spotted fever and, [739](#)
- rubella during, [848](#)
- smallpox vaccination and, [95–96](#)
- striae and, [794–795](#)
- syphilis and, [811](#)
- syringomata and, [814](#)
- varicella during, [844–846](#)

Pressure devices, for keloids, [398](#)

Pressure therapy, for keloids, [399](#)

Pressure ulcers, [414–415](#)

Pretibial myxedema, [668–671](#), [668f](#)

Prickly heat, [505](#), [507](#)

Prilocaine

- for molluscum contagiosum, [509](#)

for notalgia paresthetica, [569](#)

Primary chancre, [810–811](#)

Primary congenital lymphedema, [470](#)

Primary cutaneous B-cell lymphoma, lymphocytoma cutis and, [472](#)

Primary hypogonadism, with acanthosis nigricans, [2](#)

Primary lymphedema, [470](#)

Primary syphilis, [810](#)

Primum non nocere, [666](#)

Pritelivir, for herpes genitalis, [335–336](#)

Probenecid

- for calcinosis cutis, [125](#)
- for gonorrhea, in pregnancy, [297](#)

Probiotics

- for atopic dermatitis, [60](#)
- for warts, [858](#)

Probucol, for xanthomas, [870–872](#)

Progenitor cell transplantation

- herpes genitalis in, [335](#)
- herpes labialis in, [339](#)

Progesterone, lichen sclerosus and, [446](#)

Progesterone dermatitis, autoimmune, [70–72](#), [70f](#)

Programmed death 1 protein (PD-1), for melanoma, [485](#)

Progressive macular hypomelanosis, [363](#)

Progressive symmetric erythrokeratoderma, [255–257](#)

- absence of mutations at GJB3, GJB4, and LOR, [256](#)

Prolastin, for α_1 -antitrypsin deficiency panniculitis, [589](#)

Promazine, for delusional parasitosis, [189](#)

Promethazine, for prurigo nodularis, [672](#)

Prometheus, for cholestatic pruritus, [680](#)

Promogran, necrobiosis lipoidica with, [551](#)

Propantheline, for hyperhidrosis, [354](#)

Prophylaxis, for varicella, [846–847](#)

Propranolol

- for angiolymphoid hyperplasia with eosinophilia, [42](#)
- for aquagenic pruritus, [377](#)
- for hemangiomas, [322–323](#)
- rosacea-associated flushing with, [274](#)

Propylene glycol, [367](#)

- for Fox-Fordyce disease, [285](#)
- for seborrheic eczema, [771](#), [773](#)

Proquazone, for Jessner lymphocytic infiltrate, [385](#)

Prostacyclin

- for erythromelalgia, [259](#)
- for pulmonary hypertension, [767–768](#)
- for systemic sclerosis, [766](#)

Prostacyclin analogs

- for Raynaud's phenomenon, [764](#)
- for systemic sclerosis, [766](#)

Prostaglandin E₁

- for Behçet disease, [92](#)
- for erythromelalgia, [259](#)
- for Raynaud's phenomenon, [724](#)
- for systemic sclerosis, [724](#)

Prostaglandin inhibition, [660t](#)

Protease inhibitors, xerosis and, [879](#)

Protein C deficiency, livedoid vasculopathy, [461](#)

Protein ligand, for anthrax, [98](#)

Protein supplements, for epidermolysis bullosa, [226](#)

Proton pump inhibitors

- for burning mouth syndrome, [121](#)
- for scleroderma, [764](#)
- subacute cutaneous lupus erythematosus induced by, [797](#)

Protoporphyrin photosensitivity, [261](#)

Protoporphyrin, [262](#)

Proximal subungual onychomycosis, [823](#)

Prurigo gestationis, *See* [Atopic eruption of pregnancy](#)

Prurigo gravidarum, *See* [Intrahepatic cholestasis of pregnancy](#)

Prurigo nodularis, [672–675](#), [672f](#)

Prurigo of pregnancy, *See* [Atopic eruption of pregnancy](#)

Prurigo pigmentosa, [676–677](#), [676f](#)

Pruritic folliculitis of pregnancy, *See* [Atopic eruption of pregnancy](#)

Pruritic urticarial papules and plaques of pregnancy (PUPPP), *See* [Polymorphic eruption of pregnancy](#)

Pruritus, [606](#), [678–685](#), [678f](#)

- cholestasis of pregnancy, associated with, [681–682](#)
- cholestatic itch of, [680–681](#)
- hematologic disorders, associated with, [684–685](#)
- malignancy, associated with, [684](#)
- miscellaneous diseases associated with, [685](#)
- in notalgia paresthetica, [570](#)
- in perforating dermatoses, [616](#)
- physical examination of, [678](#)
- scabies and, [678](#), [757](#)
- xerosis and, [678](#)

Pruritus ani, [686–687](#), [686f](#)

management strategy, 686–687

Pruritus gravidarum, *See* Intrahepatic cholestasis of pregnancy

Pruritus vulvae, 688–690, 688f

- irritants and allergens, removal of, 688

Pseudoallergens, in chronic spontaneous urticaria, 841

Pseudofolliculitis barbae (PFB), 5, 691–694, 691f

Pseudomonas, folliculitis and, 278

Pseudomonas aeruginosa, 278

Pseudoxanthoma elasticum, 695–696, 695f

Psoralen

- for granuloma faciale, 308
- for sarcoidosis, 756

Psoriasis, 697–707, 697f

- erythroderma and, 250–251
- erythrodermic, 705–706
- facial and intertriginous, 697
- guttate, 698
- inverse, 698
- nail, 543–547, 543f
- palm and sole, 697
- pustular, 706–707
- in scalp, 697
- in squamous cell carcinoma, 784

Psoriatic arthritis, 543

Psychiatric disease

- burning mouth syndrome and, 120
- delusional parasitosis and, 188
- dermatitis artefacta and, 191

Psychogenic excoriation, [708–710](#), [708f](#)

Psychological treatments, for trichotillomania, [837](#)

Psychopharmacologic agents, for lichen simplex chronicus, [448](#)

Psychotherapy

- for blistering distal dactylitis in, [10030#s0090](#)
- for body dysmorphic disorder, [112](#)
- for burning mouth syndrome, [123](#)
- for dermatitis artefacta, [190](#)
- for psychogenic excoriation, [708](#), [710](#)

Pubic louse (*Phthirus pubis*), [606](#)

Pulmonary arterial hypertension, [765](#), [767](#)

Pulmonary function tests, for dermatomyositis, [199](#)

Pulmonary histoplasmosis, [347](#)

- chronic cavitary, [350](#)
- mild acute, [350](#)
- severe acute, [350](#)

Pulsed dye laser (PDL)

- for acne vulgaris, [11](#)
- for amyloidosis, [35](#)
- for angiolymphoid hyperplasia with eosinophilia, [42](#)
- for basal cell carcinoma, [564](#)
- for condyloma acuminata, [290](#)
- for dissecting cellulitis of scalp, [212](#)
- for granuloma annulare, [303](#)
- for granuloma faciale, [308](#)
- for Hailey-Hailey disease, [317](#)
- for inflammatory linear verrucous epidermal nevus, [223](#)
- for Jessner lymphocytic infiltrate, [385](#)

- for keloids, [400](#)
- for keratosis pilaris, [406t](#)
- for lymphangioma circumscriptum, [469](#)
- for mastocytoses, [491](#)
- for molluscum contagiosum, [510](#)
- for necrobiosis lipoidica, [548](#)
- for porokeratosis, [647–648](#)
- for port wine stain, [653–654](#)
 - pain reduction from, [655](#)
- for prurigo nodularis, [674](#)
- for psoriasis, [703](#)
- for psychogenic excoriation, [710](#)
- for pyogenic granuloma, [716–717](#)
- for rosacea, [748](#)
 - hair dryer use in, [748–749](#)
- for sarcoidosis, [755](#)
 - flashlamp pumped, [755](#)
- for sebaceous hyperplasia, [770](#)
- for subacute cutaneous lupus erythematosus, [801](#)
- for warts, [852](#), [856](#)
- for xanthomas, [871](#)

Pulsed infrared diode laser, for alopecia areata, [32–33](#)

Pulsed laser, for cellulite, [137](#)

Punch biopsy

- for dysplastic nevi, [68](#)
- for livedo reticularis, [457–458](#)

Punch grafting

- for chondrodermatitis nodularis helicis chronicus, [149](#)

- for epidermolysis bullosa, [227](#)
- for vitiligo, [862](#)
- Puncture, for myxoid cyst, [542](#)
- Purpura simplex, [132–133](#)
- Pustular eruption, after drug exposure, [25](#)
- Pustular psoriasis, [706–707](#)
- Pustular syphilids, [810](#)
- PUVA
 - for actinic prurigo, [18, 20](#)
 - for amyloidosis, [35](#)
 - for aquagenic pruritus, [377](#)
 - for atopic dermatitis, [60–61](#)
 - for capillaritis, [133](#)
 - for chronic actinic dermatitis, [156](#)
 - for chronic hand eczema, [28, 320](#)
 - for discoid eczema, [207](#)
 - for eosinophilic fasciitis, [216, 218](#)
 - for erythrokeratoderma, [255, 257](#)
 - for erythrokeratoderma variabilis, [257](#)
 - follicular mucinosis treated with, [276](#)
 - for granuloma annulare, [304](#)
 - for Grover disease, [835](#)
 - for hydroa vacciniforme, [351](#)
 - for irritant contact dermatitis, [380](#)
 - for Langerhans cell histiocytosis, [410](#)
 - for large plaque parapsoriasis, [599](#)
 - for lentigo, [658](#)
 - for lichen nitidus, [437](#)

for lichen planus, [441](#)
for livedo reticularis, [459](#)
for livedoid vasculopathy, [462](#)
for lymphomatoid papulosis, [479](#)
for mastocytoses, [490](#)
for morphea, [514](#)
for mycosis fungoides, [535](#)
for nail psoriasis, [546](#)
for necrobiosis lipoidica, [549](#)
for palmoplantar keratoderma, [579](#)
for palmoplantar pustulosis, [582](#)
for papular urticaria, [592](#)
for pityriases rubra pilaris, [629](#)
for pityriasis lichenoides chronica, [632](#)
for pityriasis lichenoides et varioliformis acuta, [635–636](#)
for polymorphic light eruption, [644](#)
for prurigo nodularis, [674](#)
for psoriasis, [701](#)
 erythrodermic, [705](#)
 guttate, [698](#)
 palm and sore, [697](#)
for reactive perforating collagenosis, [617](#)
for sarcoidosis, [752](#)
for scleredema, [761–763](#)
for scleromyxedema, [434](#)
for small plaque parapsoriasis, [598](#)
for subcorneal pustular dermatosis, [10236#s0080](#), [802](#)
for vitiligo, [860](#)

Pyoderma faciale, [751](#)

Pyoderma gangrenosum, [711–715](#), [711f](#)

Pyogenic granuloma, [716–718](#), [716f](#)

Pyrantel pamoate, for myiasis, [539](#)

Pyrazinamide, for tuberculosis, [838–839](#)

Pyrethrins

- for pediculosis capitis, [608](#)
- for scabies, [758–760](#)

Pyridoxine

- for erythropoietic protoporphyria, [262](#)
- for pemphigoid gestationis, [665](#)

Pyrithione, for seborrheic eczema, [773](#)

Q

Q fever, [742](#)

Quality of life, for patients with body dysmorphic disease, [111](#)

QuantiFERON-TB Gold test (QTF-G), for tuberculosis, [838](#)

Quinacrine

for dermatomyositis, [200](#)

for lupus panniculitis, [586](#)

for subacute cutaneous lupus erythematosus, [798](#)

Quinolone

for dissecting cellulitis of scalp, [212](#)

for Q fever endocarditis, [743](#)

Quinupristin-dalfopristin, in MRSA, [499](#)

R

r-PFE hyperimmune sera, [97](#)

Rabbitpox virus infection, [96](#)

Radiation, for rhinophyma, [738](#)

Radiation dermatitis, [719–721](#), [719f](#)

Radiation recall, [719](#)

Radiation therapy

for atypical fibroxanthoma, [63](#)

for basal cell carcinoma, [81](#)

for Bowen's disease, [115](#)

for chronic hand eczema, [321](#)

for dermatofibrosarcoma protuberans, [195](#), [197](#)

for epidermodysplasia verruciformis, [224–225](#)

for extramammary Paget disease, [266](#)

for Kaposi sarcoma, [392](#)

for keloids, [398](#), [400](#)

for keratoacanthoma, [403](#)

for lentigo maligna, [424](#)

for lymphangioma circumscriptum, [469](#)

for lymphocytoma cutis, [474](#)

for lymphomatoid papulosis, [477](#), [480](#)

for melanoma, [488](#)

for Merkel cell carcinoma, [496–497](#)

for myiasis, [539](#)

for nevoid basal cell carcinoma syndrome, [563](#)

for pretibial myxedema, [671](#)

for squamous cell carcinoma, [781](#)

Radio-induced malignancies, [719–721](#)

Radioembolization, for necrolytic migratory erythema, [555–556](#)

Radiofrequency treatment

for acne vulgaris, [11](#)

for angiolymphoid hyperplasia with eosinophilia, [42](#)

for cellulite, [137](#)

for neurofibromatosis type 1, [561](#)

for syringoma, [815](#)

for syringomata, [814](#)

for vulvodynia, [867](#)

Ranibizumab, for pseudoxanthoma elasticum, [696](#)

Ranula, [515](#)

Rapamycin

for dermatomyositis, [202](#)

for graft-*versus*-host disease, [301](#)

for Kaposi sarcoma, [393](#)

for Peutz-Jeghers syndrome, [623](#)

for plexiform neurofibromas, [559–561](#)

for port wine stain, [657](#)

Rapid plasma reagin test, for syphilis, [811](#)

Rapidly growing mycobacteria, [529](#)

RAS signal transduction, in neurofibromatosis type 1, [559](#)

RASA1, mutations in, port wine stain and, [653](#)

Rash

in human parvovirus B19 infection, [603](#)

in measles, [849–850](#)

in Rocky Mountain spotted fever, [739](#)

in secondary syphilis, [810](#)

Rat mite dermatitis, [591](#)

Raxibacumab, for anthrax, [97](#)

Raynaud's disease, [722–725](#), [722f](#)

Raynaud's phenomenon, [722–725](#)

re-PUVA

- for Ofuji's papuloerythroderma, [252](#)
- for palmoplantar keratoderma, [579](#)

Reactive arthritis, [726–729](#), [726f](#)

Reactive oxygen scavengers, [660t](#)

Reactive perforating collagenosis, [616](#)

Rebamipide, for Behçet disease, [92](#)

Rebound phenomenon, [746](#)

Recessive dystrophic epidermolysis bullosa, [226](#)

Recombinant bone morphogenetic protein, in neurofibromatosis type 1, [559](#)

Recombinant human epidermal growth factor, for pyoderma gangrenosum, [714](#)

Rectal infection, gonorrhea and, [295](#)

Red laser, for acne vulgaris, [10](#)

Reed syndrome, [416–417](#)

Reflex sympathetic dystrophy, [730](#)

Regenerative medicine, for androgenetic alopecia, [39](#)

Regional pain, [10217#f0010](#), [730–732](#)

Regional sympathetic nerve block, for complex regional pain syndrome, [732](#)

Relapsing polychondritis, [733–736](#), [733f](#)

Renal itch, [682–684](#)

Renal transplantation

- for nephrogenic systemic fibrosis, [558](#)

- perioral dermatitis in, [619](#)
- pseudofolliculitis barbae in, [692](#)
- for scleroderma, [768](#)
- sebaceous hyperplasia in, [769](#)

Resiquimod, for herpes genitalis, [335](#)

Respiratory conditions, yellow nail syndrome and, [881](#)

Resurfacing, of lesions, in lymphangioma circumscriptum, [467](#)

Retapamulin

- for folliculitis, [279](#)
- for furunculosis, [287](#)
- for impetigo, [370](#)

Retinal hemorrhages, pseudoxanthoma elasticum and, [695](#)

Retinoic acid

- for erythrokeratoderma variabilis, [256](#)
- for extramammary Paget disease, [267](#)
- for familial reactive perforating collagenosis, [617](#)
- for keloids, [401](#)
- for palmoplantar keratoderma, [580](#)
- for pseudofolliculitis barbae, [691](#)
- for systemic sclerosis, [766](#)

9-cis-retinoic acid, for Kaposi sarcoma, [393](#)

13-*cis*-Retinoic acid, *See* [Isotretinoin](#)

Retinoids

- for acne vulgaris, [6](#)
- for basal cell carcinoma, [566](#)
- bone toxicity, risk of, [579](#)
- for comedonal acne, [641](#)
- for confluent and reticulated papillomatosis, [161](#)

for cutaneous T-cell lymphoma, [254](#)
for Darier disease, [179](#)
erythrokeratodermas and, [255](#)
for erythrokeratoderma variabilis, [257](#)
for Fox-Fordyce disease, [285](#)
for Hailey-Hailey disease, [318](#)
for ichthyosis, [365](#), [368](#)
for keratosis pilaris, [405](#)
for lichen planopilaris, [438](#)
for palmoplantar keratoderma, [580](#)
for pityriases rubra pilaris, [629](#)
for polycystic ovary syndrome, [640](#)
for pompholyx, [319](#)
for porokeratoses, [646](#)
for psoriasis, [697–698](#), [703](#)
 erythrodermic, [705](#)
 guttate, [698](#)
for rosacea, [744](#), [750](#)
for squamous cell carcinoma, [781](#), [784](#)
for striae, [794](#)
for subcorneal pustular dermatosis, [802–803](#)
for xeroderma pigmentosum, [874–875](#)
for xerosis, [878](#)
Retinol, for cellulite, [138](#)
Retronychia, [600–601](#)
Reverse blot hybridization assay (REBA), for tuberculosis, [838–839](#)
Rheumatoid arthritis
 capillaritis with, [133](#)

complicated by vasculitis, [431](#)

Rhinophyma, [737–738](#), [737f](#)

development of malignancy and, [737](#)

rosacea and, [744](#)

Ribavirin

for Gianotti-Crosti syndrome, [294](#)

for measles, [850](#)

for porphyria cutanea tarda, [652](#)

for viral hemorrhagic fevers, [101](#)

Ricketts, ichthyosiform erythroderma and, [366](#)

Rickettsia akari, [742](#)

Rickettsia prowazekii, [741](#)

Rickettsia tsutsugamushi, [741](#)

Rickettsia typhi, [741](#)

Rickettsial infections, [739–743](#)

Rickettsial spotted fevers, [739](#)

Rickettsialpox, [742](#)

Riehl melanosis, [659](#)

Rifampicin (rifampin)

for actinomycetoma, [525](#)

for actinomycosis, [23](#)

for bacillary angiomatosis, [73](#)

for cat scratch disease, [134](#)

for cholestatic pruritus, [680](#)

for erythema induratum of Bazin, [587](#)

for fish tank granuloma, [526–527](#)

for folliculitis decalvans, [281–282](#)

for furunculosis, [286](#)

- for granuloma annulare, [305](#)
- for hidradenitis suppurativa, [344](#)
- for human monocytic ehrlichiosis, [743](#)
- for impetigo, [371](#)
- for leishmaniasis, [419](#)
- for leprosy, [426](#)
- for *Mycobacterium ulcerans* infection, [528](#)
- for psoriasis, [704](#)
- for reactive arthritis, [726](#)
- for scrub typhus, [742](#)
- for tuberculosis, [838–839](#)

Rifampin, *See* [Rifampicin](#)

Rifaximin, for rosacea, [749](#)

Rilmenidine, [749](#)

Riloncept, for cryopyrin associated periodic syndromes, [165–166](#)

Ringed keratolysis, [626–628](#), [626f](#)

Risperidone, for delusional parasitosis, [188–189](#)

Rituximab, [229](#), [231](#)

- for antiphospholipid syndrome, [47](#)
- for bullous pemphigoid, [119](#)
- for calcinosis cutis, [126](#)
- for cryoglobulinemic vasculitis, [431](#)
- for dermatitis herpetiformis, [194](#)
- for dermatomyositis, [201](#)
- for diffuse systemic sclerosis, [767](#)
- for eosinophilic fasciitis, [218](#)
- for erythema multiforme, [244](#)
- for Grover disease, [835](#)

- for Kawasaki disease, [397](#)
- for lupus erythematosus panniculitis, [586](#)
- for lymphocytoma cutis, [474](#)
- for lymphoma, [613](#)
- for mucous membrane pemphigoid, [520](#)
- for pemphigoid gestationis, [665](#)
- for pemphigus, [612](#)
- for pemphigus vulgaris, [613](#)
- for pretibial myxedema, [670](#)
- for Raynaud's phenomenon, [725](#)
- for rheumatoid arthritis, [612](#)
- for rheumatoid vasculitis, cutaneous ulcers, [432](#)
- for scleroderma, [764](#)
- for subacute cutaneous lupus erythematosus, [800](#)
- for Sweet syndrome, [809](#)
- toxicity of, [613](#)

Rivaroxaban, for livedoid vasculopathy, [462](#)

Robotic hair restoration, for androgenetic alopecia, [39](#)

Rochalimaea spp., [135](#)

Rocky Mountain spotted fever, [739–743](#), [739f](#)

- diagnosis of, [740](#)
- prevention of, [739](#)

Romidepsin, for mycosis fungoides, [536](#)

Rosacea, [744–751](#), [744f](#)

- acne, [747](#), [750](#)
- erythematotelangiectatic, [744](#), [748](#)
- flushing, [274](#), [744](#), [749](#)
- inflammatory, [744–748](#), [750](#)

- lymphedema, [744](#), [750](#)
- management strategy for, [744](#)
- ocular, [750](#)
- papulopustular, [746–748](#)
- rhinophyma and, [737](#)
- Rosacea fulminans, [751](#)
- Rosacea keratitis, [750](#)
- Roseola, [849](#)
- Ross syndrome, [354](#)
- Rotational therapy, for psoriasis, [703](#)
- Roxithromycin
 - for cellulitis, [140–141](#)
 - for confluent and reticulated papillomatosis, [163](#)
 - for granulomatous cheilitis, [315](#)
 - for prurigo pigmentosa, [677](#)
- Rubella, [848](#)
- Rubeola, [849](#)
- Ruby laser
 - for Becker nevus, [85](#)
 - for epidermal nevi, [222](#)
 - for Peutz-Jeghers syndrome, [621–622](#)
- Rucinol serum, for melasma, [495](#)
- Rupatadine
 - for chronic urticaria, [841t](#)
 - for mastocytoses, [490](#)
- Ruscogenin, for cellulite, [138](#)
- Ruxolitinib, for dermatomyositis, [202](#)

S

Salazosulfapyridine, for subcorneal pustular dermatosis, [802](#)

R-salbutamol, for discoid lupus erythematosus, [210](#)

Salicylic acid

for acne vulgaris, [10](#)

for erythrokeratoderma, [257](#)

for ichthyosis, [365](#)

for melasma, [494](#), [661](#)

for miliaria rubra, [507](#)

for molluscum contagiosum, [508](#)

for nail psoriasis, [544](#)

for palmoplantar keratoderma, [580](#)

for progressive symmetric erythrokeratoderma, [256](#)

for psoriasis, [699](#)

for reactive arthritis, [727](#)

for scabies, [757](#)

for seborrheic eczema, [771](#)

for warts, [852–855](#)

for xerosis, [878](#)

Saline, intravenous, for subcutaneous fat necrosis of newborn, [805](#)

Salmon patch (nevus simplex or angel kiss), [653](#)

SAPHO syndrome, [582](#)

Sarcoidosis, [752–756](#), [752f](#)

cutaneous, [752–756](#)

verrucous, [753](#)

erythema nodosum and, [245](#)

management strategy for, [752–756](#)

- in pseudofolliculitis barbae, 691–694
- scar, 753
- Sarcoma Group (GSF-GETO), 560
- Sarcoptes scabiei*, 757
- Saridegib, for nevoid basal cell carcinoma syndrome, 565
- Saturated solution of potassium iodide, for sporotrichosis, 777–778
- Scabicides, 757
- Scabies, 757–760, 757f
 - folliculitis and, 278
 - management strategy for, 757–760
 - in papular urticaria, 590
- Scalp
 - dermatomyositis of, 198–202
 - dissecting cellulitis of, 211–212, 211f
 - erosive pustular dermatosis in, 233, 233f
 - psoriasis of, 697, 700
 - pyoderma gangrenosum of, 711
 - seborrheic eczema of, 771, 773–774
- Scarring alopecia, 5
- Schamberg's disease, 133
- Schirmer test, for xeroderma pigmentosum, 875
- Scleredema, 761–763, 761f
- Scleredema fulminans, 762
- Sclerema neonatorum, 585
- Scleroderma, 764–768, 764f
 - internal organ involvement in, 767–768
- Sclerosing panniculitis, 585
- Sclerotherapy

- for angiolymphoid hyperplasia with eosinophilia, [42](#)
- for lymphangioma circumscriptum, [467](#)
- for myxoid cyst, [542](#)
- for pyogenic granuloma, [716–718](#)
- SCN9A gene, familial erythromelalgia, [258](#)
- Scombroid fish poisoning, [273](#)
- Scorpion stings, [102](#)
- SCORTEN, for toxic epidermal necrolysis, [832](#)
- Scrofuloderma, [839](#)
- Scrotum
 - extramammary Paget disease in, [265](#)
 - lichen simplex chronicus in, [450](#)
 - lymphangioma circumscriptum of, [468](#)
- Scrub typhus, [741](#)
- Sea anemone (*Edwardsiella lineata*), [381–382](#)
- ‘Sea lice’, [383](#)
- Sea nettle (*Chrysaora quinquecirrha*), [382](#)
- Sea wasp (*Chiropsalmus quadrumanus*), [382](#)
- Seabather’s eruption, [381–383](#)
- Sebaceous cysts, steatocystoma multiplex and, [788](#)
- Sebaceous hyperplasia, [769–770](#), [769f](#)
- Seborrheic eczema, [771–774](#), [771f](#)
 - nonscalp disease in, [771–773](#)
 - scalp disease in, [773–774](#)
- Seborrheic keratosis, [775–776](#), [775f](#)
- Seborrheic keratosis variants, [775](#)
- Secondary intention healing
 - acne keloidalis nuchae with, [5](#)

- for xanthomas, [871](#)
- Secondary lymphedema, [470](#)
- Secondary syphilis, [810–811](#)
- Secukinumab
 - for nail psoriasis, [545](#)
 - for pityriasis rubra pilaris, [630](#)
 - for psoriasis, [698](#), [702](#)
- Segmental bowel resection, for hereditary hemorrhagic telangiectasia, [331](#)
- Selective phosphodiesterase-5 (PDE-5) inhibitors, for flushing, [272](#)
- Selective serotonin reuptake inhibitors
 - for blistering distal dactylitis, [10030#p0105](#)
 - for dermatitis artefacta, [190](#)
 - for flushing, [273](#)
 - for polycythemia vera-associated pruritus, [685](#)
 - for pruritus vulvae, [688](#)
 - for psychogenic excoriation, [708](#)
 - for Raynaud's phenomenon, [722](#), [724](#)
 - for trichotillomania, [837](#)
- Selenium sulfide
 - for seborrheic eczema, [771](#), [773](#)
 - for tinea capitis, [818–819](#)
- Self-adhering foam, for chondrodermatitis nodularis helices chronicus, [148–149](#)
- Self-injury, dermatitis artefacta and, [190](#)
- "Senile freckles," [658](#)
- Sensorineural hearing loss, xeroderma pigmentosum and, [875](#)
- Sentinel lymph node biopsy
 - for malignant melanoma, [484–486](#)

- for Merkel cell carcinoma, [496–497](#)
- for squamous cell carcinoma, [782](#)
- Septal dermoplasty, for hereditary hemorrhagic telangiectasia, [331](#)
- Septal panniculitis, [584](#)
- Serologic cross-reactivity, of syphilis, yaws, and pinta, [625](#)
- Serology
 - for *Coxiella burnetii*, [743](#)
 - for hydroa vacciniforme, [351](#)
 - for leishmaniasis, [419](#)
- Lyme disease, [465](#)
 - for paracoccidioidomycosis, [594](#)
 - for Rocky Mountain spotted fever, [740](#)
 - for syphilis, [811](#)
- Serotonin, for flushing, [272](#)
- Serotonin selective reuptake inhibitors (SSRIs), for body dysmorphic disease, [113](#)
- Sertaconazole, for tinea pedis, [821](#)
- Sertraline
 - for cholestatic pruritus, [680](#)
 - for psychogenic excoriation, [709](#)
 - for trichotillomania, [837](#)
- Sevelamer hydrochloride, for pseudoxanthoma elasticum, [696](#)
- Sexually transmitted diseases treatment guidelines
 - in antiviral therapy initiation, [334](#)
 - in counseling, [336](#)
 - in hospitalization, [335](#)
 - in immunocompromised patients, [335](#)
- Sézary syndrome, [532–537](#), [532f](#)
 - combination therapy for, [253](#)

survival outcomes and prognostic factors in, [251](#)

SFN, *See* [Subcutaneous fat necrosis of newborn](#)

Shave biopsy, for dysplastic nevi, [68](#)

Shave excision, for pyogenic granuloma, [716–717](#)

Shaving

- for hirsutism, [358](#)
- pseudofolliculitis barbae induced by, [691](#)

Shaw scalpel, for rhinophyma, [738](#)

Shingles, *See* [Herpes zoster](#)

Shulman syndrome, [216](#)

Sifalimumab, for subacute cutaneous lupus erythematosus, [801](#)

Sign of Leser-Trelat, in seborrheic keratoses, [775](#)

Sildenafil

- for flushing, [272](#)
- for Raynaud's disease, [722](#)
- for Raynaud's phenomenon, [722](#)
- for systemic sclerosis-related pulmonary artery hypertension, [765](#)

Silicone

- for keloids, [399](#)
- for pitted and ringed keratolysis, [628](#)

Silver clear nylon dressing, for radiation dermatitis, [720](#)

Silver nitrate

- for aphthous stomatitis, [53](#)
- for molluscum contagiosum, [509](#)
- for pyogenic granuloma, [717](#)
- for warts, [853](#)

Silver sulfadiazine, for radiation dermatitis, [719–720](#)

Simple lentigo, [658](#)

Simulium spp. blackflies, [571](#)

Simvastatin

for alopecia areata, [33](#)

for livedo reticularis, [459](#)

for MRSA, [503](#)

Sinecatechins, for molluscum contagiosum, [511](#)

Sirolimus, *See* [Rapamycin](#)

Sitosterolemia, xanthomas and, [870](#)

Sjögren syndrome

erythema elevatum diutinum and, [239](#)

xerosis and, [878–880](#)

Sjögren-Larsson syndrome, [368](#)

Skin autografts, for epidermodysplasia verruciformis, [225](#)

Skin cooling, in erythromelalgia, [258](#)

Skin dermatophytosis, [820–822](#), [820f](#)

management strategy for, [820–822](#)

Skin examinations, for xeroderma pigmentosum, [875](#)

Skin grafting

for dissecting cellulitis of scalp, [211–212](#)

for epidermolysis bullosa, [226](#)

for foot ulcers, [415](#)

for palmoplantar keratoderma, [581](#)

for porokeratosis, [647](#)

Skin manifestation, of drug eruptions, [213](#), [213f](#)

Skin scrapings

for leishmaniasis, [418](#)

for pityriasis versicolor, [827](#)

Skin substitute dressings, for staphylococcal scalded skin syndrome, [787](#)

Skin turnover acceleration, [660t](#)

Slapped cheek sign, [603](#)

SLC39A4 gene, in acrodermatitis enteropathica, [12](#)

Slow Mohs micrographic surgery

- for dermatofibrosarcoma protuberans, [196](#)
- for lentigo maligna, [423](#)

Small bowel endoscopy, Peutz-Jeghers syndrome and, [621–622](#)

Small-bowel involvement, in hereditary hemorrhagic telangiectasia, [330–332](#)

Small plaque parapsoriasis, [597–598](#)

Smallpox, [94](#)

Smoking cessation

- necrobiosis lipoidica and, [548](#)
- palmoplantar pustulosis and, [582](#)

Smoothed inhibitors, in nevoid basal cell carcinoma syndrome, [562](#), [565](#)

Sneddon syndrome, [457](#)

Sneddon-Wilkinson disease

- hepatocellular carcinoma and, [803](#)
- rheumatoid arthritis and, [802–803](#)

See also [Subcorneal pustular dermatosis](#)

Soap substitutes, for xerosis, [879](#)

Soaps, avoidance of, for xerosis, [878](#)

Society for Immunotherapy of Cancer, on tumor immunotherapy, [486](#)

Sodium bicarbonate, in aquagenic pruritus, [376](#)

Sodium channel blockers, in erythromelalgia, [258](#)

Sodium cromoglycate

- for mastocytoses, [490](#)
- for pyoderma gangrenosum, [712](#)

Sodium fusidate

for folliculitis, [279](#)

for furunculosis, [287](#)

for impetigo, [370](#)

Sodium lactate, to ameliorate keratosis pilaris, [407](#)

Sodium nitroprusside, in erythromelalgia, [259](#)

Sodium stibogluconate, for leishmaniasis, [418](#), [420](#)

Sodium sulfacetamide, for rosacea, [746](#)

Sodium tetradecyl sulfate

for Kaposi sarcoma, [393](#)

for lymphangioma circumscriptum, [468](#)

for pyogenic granuloma, [717–718](#)

Sodium thiosulfate

for calcinosis cutis, [126](#)

for calciphylaxis, [128–129](#)

Solar lentigines, [775](#)

“Solar lentigo,” [658](#)

Solar urticaria, [375](#)

Solitary keratoacanthoma, [402–403](#)

Somatostatin, for rosacea, [747](#)

Sonic hedgehog signaling pathway (SHH)

in nevoid basal cell carcinoma syndrome, [562](#)

smoothened inhibitors of, [562](#), [565](#)

Sonidegib, for nevoid basal cell carcinoma syndrome, [565](#)

Sorafenib

for Kaposi sarcoma, [392](#)

for keratoacanthoma, [404](#)

for subcorneal pustular dermatosis, [803](#)

South American blastomycosis, [593–596](#), [593f](#)

Spectinomycin

for gonorrhea

pharyngeal infection, [297](#)

pregnancy and, [297](#)

resistance in *Neisseria* spp., [296](#)

Spinal cord astrocytoma, for xeroderma pigmentosum, [876](#)

Spinal cord stimulation

for complex regional pain syndrome, [730–732](#)

for Raynaud's phenomenon, [725](#)

Spinal cord stimulator, for vulvodynia, [867](#)

Spinal pathology, in notalgia paresthetica, [569](#)

SPINK5, in Netherton syndrome, [366](#)

Spinosad, for pediculosis capitis, [607](#)

Spironolactone

for androgenetic alopecia, [38](#)

for Becker nevus, [86](#)

for hirsutism, [359](#), [642](#)

for rosacea, [746](#)

Split-skin grafting

for lipodermatosclerosis, [456](#)

for sarcoidosis, [755](#)

Sporothrix schenckii, [777](#)

Sporotrichosis, [777–779](#), [777f](#)

guidelines in, [779](#)

Squamous cell carcinoma (SCC), [780–784](#)

actinic keratoses and, [14](#)

dissecting cellulitis of scalp and, [211](#)

- epidermal nevi and, [220](#)
- epidermolysis bullosa and, [228](#)
- intraepidermal, [114](#)
- lichen sclerosus and, [445](#)
- necrobiosis lipoidica and, [548–551](#)

Squaric acid, for warts, [854](#)

Squaric acid dibutylester, for epidermodysplasia verruciformis, [225](#)

Staged excision

- for lentigo maligna, [422–423](#), [425](#)
- for lentigo maligna melanoma, [422–423](#)

Stanford experience, in lymphomatoid papulosis, [478](#)

Stanozolol

- for hereditary angioedema, [325–326](#)
- for lipodermatosclerosis, [454](#)

Staphylococcal enterotoxin B, [97](#)

Staphylococcal furunculosis, [287](#)

Staphylococcal scalded skin syndrome, [785–787](#), [785f](#)

Staphylococcus aureus

- acne keloidalis nuchae from, [4–5](#)
- atopic dermatitis from, [56](#), [60](#)
- bed bugs from, [88](#)
- blistering distal dactylitis from, [109](#)
- folliculitis decalvans from, [281](#)
- folliculitis from, [278](#)
- furunculosis from, [286](#)
- impetigo from, [369–370](#)
- paronychia from, [600](#)
- staphylococcal scalded skin syndrome from, [785](#)

Staphylococcus epidermidis, in miliaria, [505–506](#)

Statins

for neurofibromatosis type 1, [559](#)

for Raynaud's phenomenon, [725](#)

for systemic sclerosis, [725](#)

for xerosis, [879](#)

Stromelysin-3, dermatofibrosarcoma protuberans, [196](#)

Stucco keratoses, [775](#)

Sturge-Weber syndrome, port wine stain and, [654–657](#)

Subacute cutaneous lupus erythematosus, [797–801](#), [797f](#)

erythroderma and, [251](#)

Subacute sclerosing panencephalitis, [849–850](#)

Subcision, for cellulite, [136](#)

Subcorneal pustular dermatosis, [802–804](#), [802f](#)

Subcutaneous fat necrosis of newborn, [805–806](#), [805f](#)

Subcutaneous panniculitis-like T-cell lymphoma, cytophagic histiocytic panniculitis and, [588–589](#)

Subcutaneous vulvar stimulation, for vulvodynia, [867](#)

Subfascial perforator endoscopic surgery (SEPS), for lipodermatosclerosis, [454](#)

Substrate reduction therapy, for Fabry disease, [269](#)

Sucralfate

- for aphthous stomatitis, [51](#)
- for stoma care, [792](#)

Suction, for cellulite, [137](#)

Sudamina, [505](#)

Sugar, for MRSA, [503](#)

Sulfadiazine, for paracoccidioidomycosis, [593](#)

Sulfamethoxazole monotherapy, for actinomycetoma, [523](#)

Sulfamethoxypyridazine

- for erythema elevatum diutinum, [239](#)
- for linear IgA bullous dermatosis, [451](#)
- for paracoccidioidomycosis, [593](#)

Sulfapyridine

- for dermatitis herpetiformis, [192](#)
- for erythema elevatum diutinum, [239](#)
- for linear IgA bullous dermatosis, [451](#)
- for livedoid vasculopathy, [462](#)
- for pemphigoid gestationis, [665](#)
- for subcorneal pustular dermatosis, [802–803](#)
- for Sweet syndrome, [808](#)

Sulfasalazine, [216](#), [218](#)

- for alopecia areata, [32](#)
- for lichen planus, [441–442](#)
- for psoriasis, [703](#)
- for pyoderma gangrenosum, [712](#)
- for reactive arthritis, [726](#)

Sulfonamides

in erythema elevatum diutinum, [239](#)

for mycetoma, [524](#)

for paracoccidioidomycosis, [593](#), [595](#)

Sulfur

for rosacea, [746](#)

for rosacea fulminans, [751](#)

for scabies, [757–759](#)

Sulphamethoxypyridazine, for mucous membrane pemphigoid, [518](#)

Sun avoidance

for actinic keratoses, [14](#)

for discoid lupus erythematosus, [209](#)

Sun exposure

in actinic keratoses, [14](#)

in actinic prurigo, [19](#)

in chronic actinic dermatitis, [155](#)

in hydroa vacciniforme, [351](#)

in melasma, [493](#)

in nevoid basal cell carcinoma syndrome, [563](#)

in psoriasis, [697](#)

Sunblock creams, for epidermodysplasia verruciformis, [224](#)

Sunburn lentigo, [658](#)

Sunglasses, xeroderma pigmentosum and, [873–874](#)

SunGuard, [873–874](#)

Sunitinib malate, for necrolytic migratory erythema, [556](#)

Sunscreen/sun protection

for actinic keratoses, [14](#)

chloasma for, [659–661](#)

- for discoid lupus erythematosus, [209](#)
- for erythropoietic protoporphyria, [261](#)
- for herpes labialis, [339](#)
- for hypermelanosis, [659](#)
- for melasma, [493](#)
- for nevoid basal cell carcinoma syndrome, [562](#)
- for perforating dermatoses, [616](#)
- for polymorphic light eruption, [644](#)
- for rosacea, [747](#)
- for subacute cutaneous lupus erythematosus, [797–801](#)
- Superabsorbent disposable diapers, [204](#)
- Superficial mucocele, [515](#)
- Superficial ulcers, for decubitus ulcers, [182](#)
- Supersaturated solution of potassium iodide (SSKI), for Sweet syndrome, [807](#)
- Suplatast tosilate, for angiolymphoid hyperplasia with eosinophilia, [42](#)
- Support groups, xeroderma pigmentosum and, [874](#)
- Supportive care
 - for erythema infectiosum, [603](#)
 - for Rocky Mountain spotted fever, [739](#)
 - for Stevens-Johnson syndrome, [831](#)
 - for toxic epidermal necrolysis, [830](#)
- Suprathel, for staphylococcal scalded skin syndrome, [787](#)
- Suramin, for onchocerciasis, [573](#)
- Surgery
 - for acne keloidalis nuchae, [4–5](#)
 - for androgenetic alopecia, [38](#)
 - for angiolymphoid hyperplasia with eosinophilia, [41](#)

for basal cell carcinoma, [79](#), [563](#), [565](#)
for cat scratch disease, [135](#)
for chondrodermatitis nodularis helices chronicus, [148](#)

for dermatofibrosarcoma protuberans, [196](#)
for dissecting cellulitis of scalp, [211–212](#)
of eosinophilic fasciitis, [218](#)
of Fox-Fordyce disease, [285](#)
of granuloma annulare, [303](#)
for granuloma faciale, [308](#)
for granuloma inguinale, [310](#)
for granulomatous cheilitis, [312](#), [315](#)
for hemangiomas, [324](#)
for hidradenitis suppurativa, [345](#)
for hyperhidrosis, [355–357](#)
for juvenile xanthogranuloma, [389](#)
for lentigo maligna, [423](#)
for lichen sclerosus, [445](#)
for lipodermatosclerosis, [455](#)
for lymphangioma circumscriptum, [468–469](#)
for lymphedema, [470](#)
for mastocytomas, [491](#)
for Melkersson-Rosenthal syndrome, [312](#)
for myiasis, [10162#s0050](#)
for myxoid cyst, [541](#)
for necrolytic migratory erythema, [554](#)

- for neurofibromas, [559](#)
- for neurofibromatosis type 1, [559](#)
- for nevoid basal cell carcinoma syndrome, [562](#)
- for nevus sebaceus, [567](#)
- for orf, [577](#)
- for Papillon- Lefèvre syndrome, [581](#)
- plastic, for palmoplantar keratoderma, [581](#)
- for pretibial myxedema, [668–670](#)
- for pyoderma gangrenosum, [715](#)
- for relapsing polychondritis, [734](#)
- for rhinophyma, [737](#)
- for sarcoidosis, [752](#), [755](#)
- for sebaceous hyperplasia, [769](#)
- for syringomata, [814–815](#)
- for tufted folliculitis, [282](#)

Surgical margins, for melanoma

- excisional, [486](#)
- guidelines on, [484](#), [484t](#)
- in situ, [486](#)

Swabs

- for furunculosis, [286](#)
- for paronychia, [600](#)

Sweating

- in Grover disease, [834](#)
- in miliaria, [505](#)

Sweet syndrome, [807–809](#), [807f](#)

Sympathectomy

- for complex regional pain syndrome, [732](#)

- digital artery, for Raynaud's phenomenon, [725](#)
- for hyperhidrosis, [357](#)
- Sympathetic blocks
 - for complex regional pain syndrome, [730–732](#)
 - for herpes zoster and postherpetic neuralgia, [342](#)
- Sympathetically independent pain (SIP), [731](#)
- Sympathetically maintained pain (SMP), [731](#)
- Symptomatic dermographism, [373](#)
- Symptomatic pitted keratolysis, [628](#)
- Synthetic copolymer wound dressing, for staphylococcal scalded skin syndrome, [787](#)
- Synthetic dressing, of decubitus ulcer, [185–186](#)
- Syphilis, [810–813](#), [810f](#), [813f](#)
 - diagnostics and treatment of, [811–813](#)
 - incubation period of, [810](#)
- Syringocystadenoma papilliferum, from nevus sebaceus, [567](#)
- Syringomata, [814–815](#), [814f](#)
- Systemic μ -opioid receptor antagonist, [685](#)
- Systemic immunosuppressive agents, for lichen planus, [443–444](#)
- Systemic lupus erythematosus
 - lupus panniculitis and, [584](#)
 - Mycobacterium kansasii* infection and, [529](#)
 - psychogenic excoriation and, [709](#)
- Systemic nickel allergy, [28](#)
- Systemic sclerosis, See [Scleroderma](#)

T

T- SPOT Assay TB test (T-SPOT), for tuberculosis, [838](#)

T cell deficiency, yellow nail syndrome and, [882](#)

T-cell receptor gene rearrangement studies

of large plaque parapsoriasis, [598](#)

of parapsoriasis, [597](#)

Tacalcitol

for acquired perforating dermatosis, [618](#)

for confluent and reticulated papillomatosis, [163](#)

for Grover disease, [834–835](#)

for palmoplantar keratoderma, [581](#)

for porokeratosis of Mibelli, [647](#)

for prurigo nodularis, [673](#)

for psoriasis, [700](#)

for subcorneal pustular dermatosis, [804](#)

Tacrolimus, [446](#)

for allergic contact dermatitis, [27](#)

for amyloidosis, [35](#)

for angiolymphoid hyperplasia with eosinophilia, [41](#)

for atopic dermatitis, [55](#), [59](#)

for balanitis, [78](#)

for chronic actinic dermatitis, [156](#)

for confluent and reticulated papillomatosis, [163](#)

for cutaneous lupus erythematosus, [209](#)

for cytophagic histiocytic panniculitis, [588](#)

for Darier disease, [180](#)

for dermatomyositis, [200](#)

for dyshidrotic palmar eczema, [320](#)
for erosive pustular dermatosis, [233–234](#)
for erythema annulare centrifugum, [235](#), [237](#)
for erythema dyschromicum perstans, [238](#), [238t](#)
for erythrodermic chronic actinic dermatitis, [253](#)
for follicular mucinosis, [276](#)
for folliculitis, [279](#)
for folliculitis decalvans, [282](#)
for Fox-Fordyce disease, [285](#)
for geographic tongue, [292](#)
for granuloma annulare, [303](#)
for granuloma faciale, [307](#)
for Hailey-Hailey disease, [317](#)
for inflammatory linear verrucous epidermal nevus, [222–223](#)
for jellyfish stings, [383](#)
for Jessner lymphocytic infiltrate, [385](#)
for juvenile plantar dermatosis, [387](#)
for keratosis pilaris, [407](#)
for lichen myxedematosus, [434](#)
for lichen nitidus, [436](#)
for lichen simplex chronicus, [448](#)
for lymphocytoma cutis, [474](#)
for morphea, [513–514](#)
for mucous membrane pemphigoid, [521](#)
for nail psoriasis, [544](#)
for necrobiosis lipoidica, [549](#)
for necrolytic acral erythema, [553](#)
for Netherton syndrome, [252](#)

for oral lichen planus, [575](#)
for paronychia, [600–601](#)
for pityriasis lichenoides chronica, [634](#)
for pompholyx, [319](#)
for prurigo nodularis, [675](#)
for pruritus ani, [686](#)
for psoriasis, [697](#), [700](#), [704](#)
for pyoderma gangrenosum, [711–715](#)
for reactive arthritis, [727](#)
for red baby, [253](#)
for rosacea, [747](#)
for sarcoidosis, [755–756](#)
for seborrheic eczema, [771–772](#)
for stoma care, [790](#)
for subacute cutaneous lupus erythematosus, [798](#)
for systemic lupus erythematosus, [432](#)
for vitiligo, [860–861](#)

Tadalafil

for flushing, [272](#)
for Raynaud's phenomenon, [723](#)

Talimogene laherparepvec, for melanoma, [484](#)

Tamoxifen

for autoimmune progesterone dermatitis, [71](#)
for chilblains, [146](#)
for cutaneous polyarteritis nodosa, [178](#)
for dermatomyositis, [202](#)
for hereditary hemorrhagic telangiectasia, [332](#)
for malignant peripheral nerve sheath tumors, [561](#)

for neurofibromatosis type 1, [559](#)

for scleredema, [761](#), [763](#)

Tar

for discoid eczema, [206](#)

for parapsoriasis, [598](#)

for psoriasis, [699](#)

for seborrheic eczema, [771](#)

Targeted anticancer therapies, xerosis and, [879](#)

Tattoos, lymphocytoma cutis and, [473–474](#)

Tavaborole, for onychomycosis, [823](#), [825–826](#)

Tazarotene

for acne vulgaris, [6](#)

for basal cell carcinoma, [81](#)

for confluent and reticulated papillomatosis, [163](#)

for Darier disease, [179](#)

for elastosis perforans serpiginosa, [617](#)

for erythrokeratoderma variabilis, [256](#)

for ichthyosis, [367](#)

for keratosis pilaris, [407](#)

for lentigo maligna, [425](#)

for nail psoriasis, [544](#)

for nevoid basal cell carcinoma syndrome, [566](#)

for psoriasis, [697](#), [700](#)

 facial, [697](#)

reactive arthritis and, [727](#)

Tea tree oil

for acne vulgaris, [9](#)

for scabies, [760](#)

Tear substitutes, for ocular rosacea, [751](#)

Teicoplanin

for cellulitis and erysipelas, [141](#)

for MRSA, [502](#)

Telangiectasia macularis eruptiva perstans, [489](#), [491](#)

Tendinous xanthomas, [870](#)

Tenofovir, for herpes genitalis, [335](#)

Terbinafine

for chromoblastomycosis, [151–153](#)

for mycetoma, [522](#), [524](#)

for onychomycosis, [823](#), [825–826](#)

adverse effects of, [823](#)

for paracoccidioidomycosis, [596](#)

for paronychia, [601](#)

for pityriasis versicolor, [827–828](#)

for seborrheic eczema, [771–773](#)

for sporotrichosis, [777–778](#)

for tinea capitis, [816–818](#)

for tinea pedis, [820–822](#)

Terfenadine, for erythropoietic protoporphyria, [262](#)

Tertiary syphilis, [811](#)

Testosterone, for lichen sclerosus, [446](#)

Tetmosol, for scabies, [759](#)

Tetracaine, rosacea and, [748](#)

Tetracycline(s)

for acne keloidalis nuchae, [4](#)

for actinic prurigo, [20](#)

for actinomycosis, [21–22](#)

for aphthous stomatitis, [50](#)
for bacillary angiomatosis, [74](#)
for bullous pemphigoid, [117](#)
for dermatitis herpetiformis, [193](#)
for EGFR inhibitor-induced folliculitis, [279](#)
for epidermolysis bullosa, [228](#)
for erythema elevatum diutinum, [241](#)
for erythema nodosum, [247](#)
for granulomatous cheilitis, [312](#)
for hidradenitis suppurativa, [345](#)
for lichen planopilaris, [439](#)
for linear IgA bullous dermatosis, [452](#)
for lymphogranuloma venereum, [475](#)
for MRSA, [287](#)
for mucous membrane pemphigoid, [518](#)
for ocular rosacea, [751](#)
for paronychia, [602](#)
for perioral dermatitis, [619](#)
for pitted and ringed keratolysis, [626](#)
for pityriasis lichenoides, [636](#)
for pityriasis lichenoides chronica, [633](#)
for prurigo pigmentosa, [677](#)
for Rocky Mountain spotted fever, [739](#)
for rosacea, [744–746](#), [750](#)
for rosacea fulminans, [751](#)
for sarcoidosis, [752](#), [754](#)
for steatocystoma multiplex, [788](#)
for subcorneal pustular dermatosis, [804](#)

for yaws, [625](#)

Δ^9 -tetrahydrocannabinol (dronabinol), for cholestatic pruritus, [681](#)

Tetrix cream (Cor806.805), for irritant contact dermatitis, [379](#)

Thalidomide

for actinic prurigo, [18](#), [20](#)

for angiolymphoid hyperplasia with eosinophilia, [43](#)

for aphthous stomatitis, [51](#)

for Behçet disease, [91](#)

for chronic actinic dermatitis, [157](#)

for erythema multiforme, [243](#)

for granulomatous cheilitis, [312](#), [315](#)

for hydroa vacciniforme, [353](#)

for Jessner lymphocytic infiltrate, [385](#)

for Kaposi sarcoma, [393](#)

for leprosy reaction, [426](#)

for lupus erythematosus profundus, [586–587](#)

for lymphocytoma cutis, [474](#)

for mastocytoses, [491](#)

for necrobiosis lipoidica, [551](#)

for peripheral neuropathy, [799](#)

for prurigo nodularis, [675](#)

for pyoderma gangrenosum, [714](#)

for renal itch, [684](#)

for sarcoidosis, [752](#), [754](#)

for scleromyxedema, [434](#)

for subacute cutaneous lupus erythematosus, [799](#)

for Sweet syndrome, [808](#)

for toxic epidermal necrolysis, [833](#)

Therapeutic hypothermia, for subcutaneous fat necrosis of newborn, [805–806](#)

Therapeutic lymphadenectomy, for malignant melanoma, [484](#), [488](#)

Therapeutic plasma exchange, for nephrogenic systemic fibrosis, [558](#)

Thermography, for complex regional pain syndrome, [731](#)

Thermolysis, for hirsutism, [358–359](#)

Thermosensitive lichen amyloidosis, [35–36](#)

Thermotherapy

- for chromoblastomycosis, [150](#)
- for leishmaniasis, [420](#)
- for *Mycobacterium ulcerans* infection, [529](#)
- for sporotrichosis, [777](#), [779](#)
- for warts, [855–856](#)

Thiabendazole

- for cutaneous larva migrans, [176](#)
- for scabies, [759](#)

Thiacetazone, for tuberculosis, [839](#)

Thiamphenicol

- for chancroid, [144](#)
- for granuloma inguinale, [310](#)

Thiazolidinediones, for polycystic ovary syndrome, [642](#)

Thimble jellyfish (*Linuche unguiculate*), [381–382](#)

6-thioguanine, for pustular psoriasis, [706](#)

Thiopurine methyltransferase (TPMT) deficiency, [613–614](#)

Thromboprophylaxis, for antiphospholipid syndrome, [47](#)

Thrombosis, antiphospholipid syndrome and, [46](#)

Thyroid acropathy, pretibial myxedema and, [668](#)

Thyroid dermopathy, *See* [Pretibial myxedema](#)

Thyroid disease

autoimmune, in melasma, [493–495](#)
in palmoplantar pustulosis, [582](#)
Thyrotropin binding inhibitory immunoglobulins, in pretibial myxedema, [670](#)
Tickborne illness, [102](#)
Tigecycline
for actinomycosis, [22–23](#)
for methicillin-resistant *Staphylococcus aureus*, [279–280](#)
for *Mycobacterium chelonae* infection, [530](#)
Timolol
for hemangiomas, [323](#)
for pyogenic granuloma, [718](#)
Tinea capitis, [816–819](#), [816f](#)
Tinea corporis, [820](#)
Tinea cruris, [820](#)
Tinea faciei, [820](#)
Tinea imbricata, sarcoid mimicking, [756](#)
Tinea pedis, [820–822](#), [820f](#)
Tinea unguium, [823–826](#), [823f](#)
Tinea versicolor, See [Pityriasis versicolor](#)
Tipifarnib, for neurofibromatosis type 1, [559](#)
Tissue plasminogen activator, for calciphylaxis, [129–130](#)
Tissue replacement, for foot ulcers, [415](#)
Titanium dioxide, for erythropoietic protoporphyria, [261](#)
Tobacco, subacute cutaneous lupus erythematosus and, [797](#)
Tobramycin, for *Mycobacterium chelonae* infection, [530](#)
Tocilizumab
for eosinophilic fasciitis, [219](#)
for relapsing polychondritis, [734](#)

for urticarial vasculitis, [10131#s0205](#)

α -tocopherol

- for radiation dermatitis, [720](#)
- for yellow nail syndrome, [881–882](#)

Tocoretinate, for amyloidosis, [35–36](#)

Tofacitinib

- for alopecia areata, [32](#)
- for nail psoriasis, [547](#)

Toker cells, in extramammary Paget disease, [265](#)

Topical fusidic acid, for *Staphylococcus aureus*, [279](#)

Topiramate-induced burning mouth syndrome, [121](#)

Total-body cutaneous examination, xeroderma pigmentosum and, [875–877](#)

Total body irradiation, for cytophagic histiocytic panniculitis, [589](#)

Total-body photography, xeroderma pigmentosum and, [875–877](#)

Toxic epidermal necrolysis, [214–215](#), [830–833](#), [830f](#)

Toxic shock syndrome, [252](#)

Toxoplasmosis

- pityriasis lichenoides chronica and, [632](#)
- pityriasis lichenoides et varioliformis acuta and, [635](#)

Tramadol, for postherpetic neuralgia, [342](#)

Trametinib, for melanoma, [484–485](#), [488](#)

Tranexamic acid

- for hereditary angioedema, [328](#)
- for melasma, [495](#)

Tranquilizers, for hyperhidrosis, [354](#)

Transcutaneous electrical nerve stimulation (TENS)

- for amyloidosis, [35](#)
- for lichen simplex chronicus, [448](#)

- for notalgia paresthetica, [569–570](#)
- for postherpetic neuralgia, [342](#)
- for pruritus, [618](#)
- for vulvodynia, [866](#)

Transient acantholytic dermatosis (Grover disease), [834–835](#), [834f](#)

- management strategy, [834–835](#)

Transient aplastic crisis, human parvovirus B19 infection, [603](#)

Transillumination, for myxoid cyst, [541](#)

Transplant recipients, for squamous cell carcinoma, [784](#)

Transpolydatin, for vulvodynia, [866](#)

Trastuzumab, [267](#)

Trauma

- avoidance to, for epidermolysis bullosa, [226](#)
- epidermolysis bullosa acquisita and, [229](#)

Treponema carateum, [624](#)

Treponema pallidum

- macrolide resistance in, [813](#)
- in syphilis, [810](#)

Treponema pallidum particle agglutination (TPPA) test, for syphilis, [811](#)

Treponematoses, [625](#)

Tretinoin

- for acanthosis nigricans, [2](#)
- for acne vulgaris, [8](#)
- for alopecia areata, [30](#)
- for basal cell carcinoma, [81](#)
- for confluent and reticulated papillomatosis, [163](#)
- for follicular mucinosis, [276](#)
- for Fox-Fordyce disease, [285](#)

- for geographic tongue, [292](#)
 - for melasma, [493–494](#), [660](#)
 - for molluscum contagiosum, [510](#)
 - for necrobiosis lipoidica, [550](#)
 - for oral lichen planus, [576](#)
 - for palmoplantar keratoderma, [580](#)
 - for porokeratosis, [647](#)
 - for progressive symmetric erythrokeratoderma, [256](#)
 - for pseudofolliculitis barbae, [692](#)
 - for rosacea, [746](#)
 - for scleroderma, [764](#)
 - for syringomas, [815](#)
 - for verrucous epidermal nevus, [222](#)
- Triactive system, for cellulite, [137](#)
- Triamcinol1 acetone, for yellow nail syndrome, [882](#)
- Triamcinolone
- for acne keloidalis nuchae, [4](#)
 - for alopecia areata, [30–33](#)
 - for aphthous stomatitis, [49](#), [51](#)
 - for chondrodermatitis nodularis helices chronicus, [147](#)
 - for cutaneous candidiasis, [172](#)
 - for discoid lupus erythematosus, [797](#)
 - for erosive pustular dermatosis, [233](#)
 - for erythrokeratoderma variabilis, [256](#)
 - for Fox-Fordyce disease, [285](#)
 - for granuloma annulare, [302](#)
 - for granuloma faciale, [308](#)
 - for granulomatous cheilitis, [315](#)

for keloids, [399](#)
for lichen myxedematosus, [434](#)
for lichen planopilaris, [438](#)
for lichen simplex chronicus, [448](#)
for lipodermatosclerosis, [456](#)
for miliaria profunda, [507](#)
for mucocèles, [515](#)
for mucous membrane pemphigoid, [517](#)
for nail psoriasis, [544](#)
for necrobiosis lipoidica, [549](#)
for oral lichen planus, [575](#)
for palmoplantar pustulosis, [583](#)
for papular urticaria, [590](#)
for paronychia, [602](#)
for pompholyx, [319](#)
for pretibial myxedema, [669](#)
for prurigo nodularis, [672](#)
for pruritus vulvae, [688](#), [690](#)
for pyoderma gangrenosum, [712](#)
for pyogenic granuloma, [718](#)
for rosacea, [746](#)
for sarcoidosis, [752–753](#), [756](#)
for vulvodynia, [865](#)

Triazoles

for eumycetoma, [524](#)
for histoplasmosis, [347](#)

Trichloroacetic acid

for acanthosis nigricans, [2](#)

- for acne vulgaris, [11](#)
- for actinic keratoses, [17](#)
- for condyloma acuminata, [290](#)
- for Grover disease, [835](#)
- for leishmaniasis, [421](#)
- for Peutz-Jeghers syndrome, [621](#)
- for seborrheic keratosis, [775–776](#)
- for syringomata, [815](#)
- for warts, [855](#)
- for xanthomas, [872](#)

Trichobezoars, [836](#)

Trichoblastoma, from nevus sebaceus, [567](#)

Trichophagia, [836](#)

Trichophyton

- dermatophytosis and, [820](#)
- tinea capitis and, [816](#), [818](#)

Trichophyton interdigitale, onychomycosis and, [823](#)

Trichophyton mentagrophytes

- dermatophytosis and, [820](#)
- palmoplantar keratoderma and, [580](#)

Trichophyton rubrum

- dermatophytosis and, [820](#)
- onychomycosis and, [823](#)

Trichophyton tonsurans, tinea capitis and, [816](#), [818](#)

Trichophyton violaceum, tinea capitis and, [816](#), [818](#)

Trichorhizophagia, [836](#)

Trichotillomania, [836–837](#), [836f](#)

Triclosan

for aphthous stomatitis, [50](#)
for impetigo, [371](#)
Tricyclic antidepressants
for complex regional pain syndrome, [731](#)
for postherpetic neuralgia, [340](#), [341t](#)
for prurigo nodularis, [672](#)
for psychogenic excoriation, [708](#)
for vulvodynia, [865](#)
Triethanolamine, for hyperhidrosis, [355](#)
Trifluorothymidine (TFT), for herpes labialis, [337](#)
Triiodothyronine, for Raynaud's phenomenon, [725](#)
Trimethoprim
for epidermolysis bullosa, [228](#)
for *Mycobacterium fortuitum* infection, [530t](#)
Trimethoprim-sulfamethoxazole
for granuloma inguinale, [309–310](#)
for MRSA, [279](#), [287](#), [499](#), [501](#)
for mycetoma, [522](#)
for paracoccidioidomycosis, [593](#)
for pediculosis capitis, [608](#)
TriPollar radiofrequency device, for striae, [795](#)
Trolamine, for radiation dermatitis, [720](#)
Trovaflaxacin, for granuloma inguinale, [310](#)
True jellyfish (Schyphozoans), [381](#)
Tryptase, in mastocytoses, [489](#)
Tryptophan ingestion, in eosinophilic fasciitis, [217](#)
Tuberculids, [838–839](#)
Tuberculin skin test (TST), [838](#)

Tuberculoid leprosy, [426](#)

Tuberculosis, [838–839](#), [838f](#)

Tuberculosis verrucosa cutis, [838–839](#)

Tuberculous antigen, [838](#)

Tuberculous chancre, [838](#)

Tuberoeruptive xanthomas, [870](#)

Tuberous xanthomas, [870](#)

Tufted folliculitis, [282](#)

Tularemia, [98](#)

- in children, [99](#)
- WHO guidelines on, [99](#)

Tumor immunotherapy, for melanoma, [486](#)

Tumors, from nevus sebaceus, [567–568](#)

Turpentine, for myiasis, [539–540](#)

Tweezing, for hirsutism, [358–359](#)

Type 1 diabetes, keratosis pilaris in, [405–408](#)

Tyrosinase inhibition, [660t](#)

Tyrosine, restriction of, palmoplantar keratoderma and, [579](#)

Tyrosine kinase inhibitor, for mastocytoses, [491–492](#)

U

Udenafil, for Raynaud's phenomenon, [723](#)

Ulcer(s)

cutaneous polyarteritis nodosa, [178](#)

decubitus, [181–186](#), [181f](#)

genital, chancroid, [143](#)

granuloma inguinale and, [309–310](#)

livedo reticularis and, [457](#)

livedoid vasculopathy and, [460](#)

in MRSA, [503](#)

paracoccidioidomycosis and, [593](#)

penile, [482](#)

transient genital, [475](#)

Ulcerative colitis

erythema elevatum diutinum and, [241](#)

pyoderma gangrenosum and, [711](#), [714–715](#)

Wells syndrome and, [868–869](#)

Ulceroglandular tularemia, [98](#)

Ulesfia, for pediculosis capitis, [607](#)

Ulinastatin, for Kawasaki disease, [397](#)

Ultrapulse CO₂ laser, for basal cell carcinoma, [564](#)

Ultrasonic massage, for scleredema, [763](#)

Ultrasound

endobronchial, for relapsing polychondritis, [734](#)

for hemangiomas, [322–324](#)

for lipodermatosclerosis, [456](#)

for morphea, [513](#)

- for myiasis, [538–539](#)
- for myxoid cyst, [541](#)
- for nevoid basal cell carcinoma syndrome, [562](#)
- for PCOS, [359](#)
- pretibial, for pretibial myxedema, [668](#)
- for subcutaneous fat necrosis of newborn, [805–806](#)
- Ultrasound-guided sclerotherapy (UGS), for lipodermatosclerosis, [456](#)
- Ultraviolet A1 phototherapy
 - for alopecia areata, [31](#)
 - for atopic dermatitis, [61](#)
 - for granuloma annulare, [303](#)
 - for Grover disease, [835](#)
 - for hydroa vacciniforme, [353](#)
 - for lichen sclerosus, [447](#)
 - for morphea, [513](#)
 - for pityriases rubra pilaris, [630](#)
 - for pityriasis lichenoides chronica, [634](#)
 - for pityriasis rosea, [639](#)
 - for sarcoidosis, [756](#)
 - for scleredema, [762](#)
 - for scleroderma, [764](#)
 - for systemic sclerosis, [766](#)
 - for urticaria pigmentosa, [491](#)
 - of widespread plaque-type, nodular, and erythrodermic mycosis fungoides, [253](#)
- Ultraviolet B phototherapy
 - for allergic contact dermatitis and photoallergy, [28](#)
 - for amyloidosis, [34](#)
 - for aquagenic pruritus, [373](#)

- for atopic dermatitis, [61](#)
- for atopic eruption of pregnancy, [667](#)
- for chronic actinic dermatitis, [156](#)
- for Fox-Fordyce disease, [285](#)
- for intrahepatic cholestasis of pregnancy, [666](#)
- for mastocytoses, [490](#)
- narrowband, for pityriasis lichenoides chronica, [633](#)
- for perforating dermatoses, [616](#)
- for pityriasis lichenoides et varioliformis acuta, [636](#)
- for pityriasis rosea, [638](#)
- for polymorphic light eruption, [644](#)
- for prurigo nodularis, [673](#)
- for psoriasis, [697](#), [701](#), [703](#)
- for reactive perforating collagenosis, [617](#)
- for subcorneal pustular dermatosis, [802](#)
- for uremic pruritus, [617](#)

Ultraviolet phototherapy, for pruritus, [679](#)

Ultraviolet (UV) radiation, for pityriasis rosea, [638](#)

Undifferentiated pleomorphic sarcoma (UPS), [63–64](#)

Unilateral lateral thoracic syndrome, (asymmetric periflexural exanthema), [603](#)

Unna boot, for lichen simplex chronicus, [448](#)

Urea

- for ameliorate keratosis pilaris, [407](#)
- erythrokeratodermas and, [255](#)
- for ichthyosis, [367](#)
- for palmoplantar keratoderma, [579](#)
- for progressive symmetric erythrokeratoderma, [256](#)
- for tinea pedis, [822](#)

- for xerosis, [878–879](#)
- Uremic pruritus, *See* [Renal itch](#)
- Urethra, Bowen's disease involving, [115](#)
- Urethritis, gonococcal, [295](#)
- Uroporphyrinogen decarboxylase genes, [650](#)
- Urostomy dermatitis, [790](#)
- Ursodeoxycholic acid
 - for cholestatic pruritus, [680](#)
 - for erythropoietic protoporphyria, [263](#)
 - for intrahepatic cholestasis of pregnancy, [665](#)
 - for renal itch, [682](#)
- Urticaria, [840–843](#), [840f](#)
- Urticaria, papular, [590–592](#), [590f](#)
- Urticaria pigmentosa, [489–490](#), [489f](#)
- Urticarial vasculitis, [431](#)
- Urticarias, inducible, [372](#), [372f](#)
- Ustekinumab
 - for erythrodermic psoriasis, [254](#)
 - for nail psoriasis, [545](#)
 - for palmoplantar pustulosis, [583](#)
 - for pityriases rubra pilaris, [630](#)
 - for psoriasis, [698](#), [702](#), [704](#)
 - erythrodermic, [705](#)
 - pustular, [706](#)
 - for pyoderma gangrenosum, [715](#)
- UV meters, handheld, for xeroderma pigmentosum, [874](#)
- UV protection
 - for herpes labialis, [337](#)

for xeroderma pigmentosum, [873](#), [876](#)

V

V600E-mutated BRAF, in melanoma, [484–485](#)

Vaccines

for anthrax, [97](#)

for cutaneous leishmaniasis (CL), [418](#)

for Gianotti-Crosti syndrome, [293](#)

for herpes simplex, [336](#)

for herpes zoster, [340](#), [342](#)

for influenza, myocarditis/pericarditis following, [96](#)

for Lyme disease, [465](#)

for lymphocytoma cutis, [473](#)

for measles, [850](#)

for postherpetic neuralgia, [342](#)

for rubella, [848](#)

for smallpox, [95](#)

for varicella, [844](#), [846–847](#)

for varicella zoster virus, [342](#)

Vaccinia, [96](#)

Vaccinia immune globulin, for smallpox, [95](#)

Valaciclovir

for herpes genitalis, [333–336](#)

for herpes labialis, [337–339](#)

for herpes zoster, [340–343](#)

for hydroa vacciniforme, [352](#)

for postherpetic neuralgia, [341](#)

for varicella, [845](#)

Valganciclovir, for Kaposi sarcoma, [394](#)

Vancomycin

for MRSA, [279–280](#), [499–500](#), [502](#)

for staphylococcal scalded skin syndrome, [786](#)

Vardenafil

for flushing, [272](#)

for Raynaud's phenomenon, [723](#)

Varicella, [844–847](#), [844f](#)

contacts with, [342](#)

Varicella pneumonitis, [844–846](#)

Varicella zoster virus (VZV)

latent, [340](#)

vaccine for, [342](#)

Vascular lasers

for pyogenic granuloma, [716](#)

for rosacea, [744](#)

Vasculitides, [429](#)

Vasculitis

in bedbug bite reaction, [89](#)

leukocytoclastic, [429–432](#), [429f](#)

nodular, [584](#), [587](#)

urticarial, [431](#)

Vaseline, for myiasis, [539](#)

Vasoconstrictors, for rosacea, [744](#)

Vasodilators

for erythromelalgia, [258](#)

for flushing, [272](#)

for Raynaud's phenomenon, [724](#)

for scleroderma, [764](#)

Vectorborne disease, [102–104](#)

VelaSmooth system, for cellulite, [137](#)

Vemurafenib

- for keratoacanthoma, [404](#)
- for melanoma, [484–485](#), [487–488](#)

Vena cava filters, inferior, for antiphospholipid syndrome, [48](#)

Venereal disease research laboratory (VDRL) test, for syphilis, [811](#)

Venesection, for porphyria cutanea tarda, [651](#)

Venlafaxine

- for body dysmorphic disorder., [112](#)
- for psychogenic excoriation, [710](#)

Venom, centipede, [103](#)

Venous leg ulcers, [414](#), [456](#)

- compression for, [415](#)
- pentoxifylline for, [415](#)

Ventilation devices, for relapsing polychondritis, [734](#)

Verapamil, for keloids, [401](#)

Verruciform xanthomas, [870](#)

Verrucous epidermal nevi, [221–222](#)

Versajet Hydrosurgery System, for rhinophyma, [738](#)

Vesicular hand dermatitis, [320](#)

Vesiculobullous Darier's disease, [180](#)

Vestibulectomy, for vulvodynia, [864](#), [866](#)

Vidarabine, for herpes labialis, [337](#), [339](#)

Video capsule endoscopy, for hereditary hemorrhagic telangiectasia, [331](#)

Vinblastine

- for Kaposi sarcoma, [392–393](#)
- for Langerhans cell histiocytosis, [409](#)

Vincristine

for cytophagic histiocytic panniculitis, [588](#)

for hemangiomas, [324](#)

for scleromyxedema, [435](#)

Vinegar, for jellyfish stings, [383](#)

Viral exanthems, [848–851](#), [848f](#)

Gianotti-Crosti syndrome and, [293](#)

Viral hemorrhagic fevers, [100](#)

Viral hepatitis, pigmented purpura dermatosis and, [132](#)

Viral warts, [852–858](#), [852f](#)

Virus-like inclusions, in malignant atrophic papulosis, [481](#)

Visilizumab, for pyoderma gangrenosum, [715](#)

Vismodegib

for basal cell carcinoma, [565](#)

intermittent therapy of, [566](#)

for keratocystic odontogenic tumors, [565](#)

for medulloblastoma, [565](#)

for nevoid basal cell carcinoma syndrome, [562](#), [566](#)

for xeroderma pigmentosum, [874–875](#)

Vitamin A

for Grover disease, [834](#)

for measles, [850](#)

for palmoplantar keratoderma, [580](#)

Vitamin B₁₂

for aphthous stomatitis, [53](#)

for erythema nodosum, [247](#)

Vitamin D

deficiency of, ichthyosiform erythroderma and, [366](#)

- levels, in erythropoietic protoporphyria, [262](#)
- for pemphigus, [612](#)
- for porokeratoses, [646](#)
- for psoriasis, [697](#)
- for relapsing polychondritis, [734](#)
- withdrawal of, in subcutaneous fat necrosis of newborn, [805](#)
- for xeroderma pigmentosum, [874](#)

Vitamin D₃, for subcorneal pustular dermatosis, [804](#)

Vitamin E

- for actinic prurigo, [20](#)
- for granuloma annulare, [306](#)
- for porphyria cutanea tarda, [650](#), [652](#)
- for subcorneal pustular dermatosis, [804](#)
- for yellow nail syndrome, [881](#)

Vitamin K, for calciphylaxis, [129](#)

Vitamin K antagonists, livedoid vasculopathy, [461](#)

Vitiligo, [859–863](#), [859f](#)

- autoimmune diseases, [860](#)
- management strategy, [859–860](#)

Vohwinkel syndrome, [581](#)

von Recklinghausen disease, *See* [Neurofibromatosis type 1](#)

Voriconazole

- for blastomycosis, [106](#)
- for chromoblastomycosis, [153](#)
- for coccidioidomycosis, [159](#)
- for cryptococcosis, [168](#), [170](#)
- for fungal infections, [106](#)
- for histoplasmosis, [347](#), [350](#)

- for mycetoma, [524](#)
- for paracoccidioidomycosis, [593](#), [596](#)
- Vorinostat, for mycosis fungoides, [536](#)
- Vulva
 - extramammary Paget disease of, [267](#)
 - lichen sclerosus in, [445–447](#)
 - lichen simplex chronicus in, [449](#)
 - lymphangioma circumscriptum of, [468](#)
 - pruritus in, [688–690](#), [688f](#)
- Vulval Darier's disease, [180](#)
- Vulvar intraepithelial neoplasia (VIN), pruritus vulvae and, [689](#)
- Vulvodynia, [864–867](#)
 - placebo and, [865–866](#)
- VZIG
 - for immunocompromised individuals, [844–845](#)
 - for neonates, [844–845](#)
 - pregnancy and, [844–846](#)
 - for varicella prophylaxis, [846](#)

W

Wake sign, scabies and, [758](#)

Warfarin

- for antiphospholipid syndrome, [47](#)

- for calcinosis cutis, [126](#)

- for cutaneous polyarteritis nodosa, [178](#)

- for livedoid vasculopathy, [461](#)

Warm compresses, for paronychia, [600](#)

Warming devices, for Raynaud's disease, [722](#)

Warts, condyloma acuminata, [288](#), [288f](#)

Wash E45, for xerosis, [879](#)

Wasp sting, [104](#)

Water contact, pruritus, [372t](#)

Water-repellant silicone ointment, for pitted and ringed keratolysis, [626](#), [628](#)

Weber-Christian disease, [584](#)

Weight management, in polycystic ovary syndrome, [641](#)

Wells syndrome, [868–869](#), [868f](#)

- associations, [869t](#)

- management strategy, [868–869](#)

“Wet flushing,” [272](#)

Wet-work occupations, [379](#)

Wet wraps, for atopic dermatitis, [54](#), [58–59](#)

White superficial onychomycosis, [823](#)

Whitfield ointment, for pitted and ringed keratolysis, [626](#)

Wide local excision (WLE)

- for atypical fibroxanthoma, [63](#)

- for malignant melanoma, [484](#)
- for Merkel cell carcinoma, [497](#)
- Withdrawal, in perioral dermatitis, [619](#)
- Wolbachia*, [573](#)
- Wolfe graft, for myxoid cyst, [542](#)
- Wood lamp
 - for lentigo maligna, [422](#)
 - for melasma, [493](#)
- Wood light examination, for tinea capitis, [816–817](#)
- World Health Organization tuberculosis treatment guidelines, [839](#)
- Wound care
 - for epidermolysis bullosa, [227](#)
 - for leg ulcers, [414](#)
 - for livedoid vasculopathy, [460](#)
 - for pyoderma gangrenosum, [711](#)

X

X-ray epilation, for dissecting cellulitis of scalp, [211](#)

Xanthelasma palpebrarum, [871–872](#)

Xanthogranuloma, juvenile, [388–390](#), [388f](#)

Xanthoma striatum palmare, [870](#)

Xanthomas, [870–872](#), [870f](#)

Xanthomatosis

 cerebrotendinous, [870](#)

 perifollicular, [284](#)

XEN402, in familial erythromelalgia, [259](#)

Xeroderma pigmentosum, [873–877](#), [873f](#)

 diagnosis of, [874](#)

 treatment of skin cancers and, [875](#)

Xerosis, [878–880](#), [878f](#)

 for discoid eczema, [206](#)

Xylitol chewing gum, for angular cheilitis, [45](#)

Xylocaine, for postherpetic neuralgia, [342](#)

Y

Yaws, [624–625](#), [624f](#)

Yellow nail syndrome, [881–882](#), [881f](#), [881t](#)

Yersinia pestis, [97](#), [99–100](#)

Z

Zafirlukast, for cold urticaria, [10058#s0125](#)

Zileuton, for acne vulgaris, [9](#)

Zinc

for acne vulgaris, [8](#)

for acrodermatitis enteropathica, [12](#)

for aphthous stomatitis, [52](#)

for Behçet disease, [91](#)

for diaper dermatitis, [204–205](#)

for dissecting cellulitis of scalp, [211–212](#)

for epidermodysplasia verruciformis, [225](#)

for epidermolysis bullosa, [226](#)

for erosive pustular dermatosis, [234](#)

for erythema multiforme, [244](#)

for erythropoietic protoporphyria, [261](#)

for folliculitis decalvans, [281–282](#)

for juvenile plantar dermatosis, [387](#)

for leishmaniasis, [421](#)

for pruritus ani, [686](#)

for pruritus vulvae, [688](#)

radiation dermatitis and, [720](#)

for renal itch, [683](#)

for rosacea, [748](#)

for seborrheic eczema, [771](#)

for warts, [854–855](#), [858](#)

for yellow nail syndrome, [881–882](#)

Zinc deficiency, in necrolytic acral erythema, [552](#)

Zinc replacement therapy, for burning mouth syndrome, [122](#)

Ziprasidone, for delusional parasitosis, [189](#)

Zoon's balanitis, [78](#)

Zostavax, [340](#)

Zoster, herpes, [340–343](#), [340f](#)

Dedication	79
Evidence Levels	80
Credits	82
1. Acanthosis nigricans	84
Management Strategy	85
2. Acne keloidalis nuchae	93
Management Strategy	94
3. Acne vulgaris	99
Management Strategy	100
4. Acrodermatitis enteropathica	118
Management Strategy	119
5. Actinic keratoses	123
Management Strategy	123
6. Actinic prurigo	136
Management Strategy	137
7. Actinomycosis	146
Management Strategy	147
8. Acute generalized exanthematous pustulosis	155
Management Strategy	156
9. Allergic contact dermatitis and photoallergy	163
Management strategy	165
10. Alopecia areata	173
Management Strategy	173
11. Amyloidosis	190

Management Strategy	193
12. Androgenetic alopecia	199
Management Strategy	201
13. Angiolymphoid hyperplasia with eosinophilia	210
Management Strategy	211
14. Angular cheilitis	219
Management Strategy	220
15. Antiphospholipid syndrome	224
Management Strategy	225
16. Aphthous stomatitis	233
Management Strategy	234
17. Atopic dermatitis	249
Management Strategy	250
18. Atypical fibroxanthoma	280
Management Strategy	282
19. Atypical nevi	288
Management Strategy	292
Specific Investigations	293
First-Line Therapies	296
20. Autoimmune progesterone dermatitis	299
Management Strategy	300
21. Bacillary angiomatosis	308
Management Strategy	309
22. Balanitis	316
Management Strategy	317
23. Basal cell carcinoma	327
Management Strategy	328
24. Becker nevus	342
Management Strategy	343
25. Bed bugs	351
Management Strategy	351
26. Behçet disease	359
Management Strategy	360

27. Bioterrorism	373
Smallpox	373
Management Strategy	374
Anthrax	381
Management Strategy	382
Tularemia	388
Management Strategy	389
Plague	392
Management Strategy	392
Viral hemorrhagic fevers	395
Management Strategy	395
28. Bites and stings	400
Management Strategy	401
29. Blastomycosis	414
Management Strategy	415
Guidelines	421
30. Blistering distal dactylitis	423
Management Strategy	424
31. Body dysmorphic disorder (dermatologic nondisease)	427
Management Strategy	428
32. Bowen disease and erythroplasia of Queyrat	438
Diagnosis	439
Management Strategy	439
33. Bullous pemphigoid	445
Management Strategy	446
34. Burning mouth syndrome (glossodynia)	458
Management Strategy	459
Specific Investigations	460
35. Calcinosis cutis	469
Management Strategy	471
36. Calciphylaxis	481
Management Strategy	482
37. Capillaritis (pigmented purpuric dermatoses)	489
Management Strategy	491

38. Cat scratch disease	500
Management Strategy	501
39. Cellulite	507
Management Strategy	508
40. Cellulitis and erysipelas	516
Management Strategy	517
41. Chancroid	529
Diagnosis and Management Strategy	530
Special considerations: Evacuation of buboes and unusual manifestations	532
42. Chilblains	534
Management Strategy	535
43. Chondrodermatitis nodularis helices chronicus	542
Management Strategy	544
44. Chromoblastomycosis	552
Management Strategy	553
45. Chronic actinic dermatitis	564
Management Strategy	566
46. Coccidioidomycosis	577
Management Strategy	578
Current Guidelines	584
47. Confluent and reticulated papillomatosis	585
Management Strategy	586
48. Cryopyrin-associated periodic syndromes (CAPS)	597
Management Strategy	598
Second-Line Therapy	603
49. Cryptococcosis	605
Management Strategy	606
Third-Line Therapies	612
Guidelines	612
50. Cutaneous candidiasis and chronic mucocutaneous candidiasis	614
Cutaneous candidiasis	615

Management Strategy	616
Chronic mucocutaneous candidiasis	620
Management Strategy	621
51. Cutaneous larva migrans	627
Management Strategy	628
Specific Investigations	628
52. Cutaneous polyarteritis nodosa	633
Management Strategy	634
53. Darier disease	641
Management Strategy	642
54. Decubitus ulcers	648
Management Strategy	649
55. Delusions of parasitosis	668
Management Strategy	669
56. Dermatitis artefacta	679
Management Strategy	681
57. Dermatitis herpetiformis	686
Management Strategy	687
58. Dermatofibrosarcoma protuberans	694
Management Strategy	695
59. Dermatomyositis	702
Management Strategy	703
60. Diaper dermatitis	718
Management Strategy	719
61. Discoid (Nummular) eczema	725
Management Strategy	726
62. Discoid lupus erythematosus	734
Management Strategy	736
63. Dissecting cellulitis of the scalp	742
Management Strategy	743
64. Drug eruptions	749
Management Strategy	750
65. Eosinophilic fasciitis	757

Management Strategy	758
66. Epidermal nevi	769
Management Strategy	770
Verrucous epidermal nevi	773
Inflammatory/dysplastic epidermal nevi	777
67. Epidermodysplasia verruciformis	782
Management Strategy	783
68. Epidermolysis bullosa	789
Management Strategy	790
69. Epidermolysis bullosa acquisita	800
Management Strategy	801
70. Erosive pustular dermatosis	812
Management Strategy	814
71. Erythema annulare centrifugum	819
Management Strategy	821
72. Erythema dyschromicum perstans	831
Management Strategy	833
Therapy	833
73. Erythema elevatum diutinum	836
Management Strategy	837
74. Erythema multiforme	847
Management Strategy	848
75. Erythema nodosum	857
Management Strategies	859
76. Erythrasma	868
Management Strategy	868
77. Erythroderma	873
Management Strategy	874
78. Erythrokeratodermas	890
Management Strategy	892
79. Erythromelalgia	901
Management Strategy	902
80. Erythropoietic protoporphyria	910

Management Strategy	911
81. Extramammary Paget disease	922
Management Strategy	923
82. Fabry disease	931
Management Strategy	932
83. Flushing	943
Management Strategy	944
84. Follicular mucinosis	953
Management Strategy	954
85. Folliculitis	962
Management Strategy	963
86. Folliculitis decalvans	970
Management Strategy	971
87. Fox–Fordyce disease	978
Management Strategy	980
88. Furunculosis	986
Management Strategy	987
89. Condyloma acuminata	993
Management Strategy	994
90. Geographic tongue	1003
Management Strategy	1004
91. Gianotti–Crosti syndrome	1008
Management Strategy	1009
92. Gonorrhea	1015
Management Strategy	1015
Special Considerations	1022
93. Graft-versus-host disease	1025
Management Strategy	1026
Acute GVHD	1027
Chronic GVHD	1033
94. Granuloma annulare	1040
Management Strategy	1041
Localized Granuloma Annulare	1042

Generalized (Disseminated) Granuloma Annulare	1047
95. Granuloma faciale	1058
Management Strategy	1060
96. Granuloma inguinale	1066
Management Strategy	1067
Special considerations	1073
97. Granulomatous cheilitis	1074
Management Strategy	1075
98. Hailey–Hailey disease	1088
Management Strategy	1089
99. Hand and foot eczema (endogenous, dyshidrotic eczema, pompholyx)	1097
Management Strategy	1098
100. Hemangiomas	1107
Management Strategy	1109
101. Hereditary angioedema	1118
Management Strategy	1120
Acute Angioedema	1120
Acute Angioedema	1124
Long-Term Prophylaxis of Hereditary Angioedema	1127
Prevention of Relapse Due to Dental and Surgical Interventions	1129
Treatment in Children	1130
Hereditary Angioedema With Normal C1inh	1130
